BACKGROUND. Various perceptions, and practices have been associated with the COVID-19 pandemic. In this study, we assessed the perception and practices regarding COVID-19 among residents in selected urban communities of Ibadan, Oyo State, Nigeria. **METHODS.** A descriptive cross-sectional study design using a multi-stage sampling technique was used to recruit 360 respondents (Mean age: 33.2 ± 10.6 years; 62.5% females) from households in Ibadan. Data were collected using an interviewer-administered questionnaire from 3rd - 6th June 2020. Those who demonstrated washing of the palm, back of the hand, spaces between the fingers, fingernails, wrist, and thumbs had 6 points and were categorized to have had a good practice of handwashing. Descriptive statistics were conducted. Bivariate analyses of sociodemographic characteristics and good hand washing practices were conducted using Chi-square test. P-values <0.05 were statistically significant. **RESULTS.** Going to the hospital (95%) and calling the COVID-19 help number (58.3%) were the frequently reported practices among respondents following the development of COVID-19 symptoms. Also, 89 (26%) knew they could contract COVID-19, while 41 (12%) perceived it as an exaggerated event. The effects most frequently reported by respondents were hunger/low income (48.8%) and academic delay (8.8%). Use of face masks by 64.5% and social distancing (48%) were the most frequently reported practices for prevention. Only 71(20.8%) demonstrated good handwashing practices. The perception of likelihood to contract COVID-19 and practices to prevent COVID-19 had a weak correlation of 0.239($p<0.001$). **CONCLUSION.** Gaps exist in the practices that prevent COVID-19. There is a need to improve handwashing, use of face masks and other practices that prevent COVID-19. Implications across public health communication and policies were stated.

14

15 **Abstract**

16

17 **BACKGROUND.**

18 Various perceptions, and practices have been associated with the COVID-19 pandemic. In this
19 study, we assessed the perception and practices regarding COVID-19 among residents in
20 selected urban communities of Ibadan, Oyo State, Nigeria.

21

22 **METHODS.**

23 A descriptive cross-sectional study design using a multi-stage sampling technique was used to
24 recruit 360 respondents (Mean age: 33.2 ± 10.6 years; 62.5% females) from households in
25 Ibadan. Data were collected using an interviewer-administered questionnaire from 3rd – 6th June
26 2020. Those who demonstrated washing of the palm, back of the hand, spaces between the
27 fingers, fingernails, wrist, and thumbs had 6 points and were categorized to have had a good
28 practice of handwashing. Descriptive statistics were conducted. Bivariate analyses of
29 sociodemographic characteristics and good hand washing practices were conducted using Chi-
30 square test. P-values <0.05 were statistically significant.

31

32 RESULTS.

33 Going to the hospital (95%) and calling the COVID-19 help number (58.3%) were the frequently
34 reported practices among respondents following the development of COVID-19 symptoms. Also,
35 89 (26%) knew they could contract COVID-19, while 41 (12%) perceived it as an exaggerated
36 event. The effects most frequently reported by respondents were hunger/low income (48.8%) and
37 academic delay (8.8%). Use of face masks by 64.5% and social distancing (48%) were the most
38 frequently reported practices for prevention. Only 71(20.8%) demonstrated good handwashing
39 practices. The perception of likelihood to contract COVID-19 and practices to prevent COVID-
40 19 had a weak correlation of 0.239($p<0.001$).

41

42 CONCLUSION.

43 Gaps exist in the practices that prevent COVID-19. There is a need to improve handwashing, use
44 of face masks and other practices that prevent COVID-19. Implications across public health
45 communication and policies were stated.

46

47 Keywords: Coronavirus, COVID-19, risk perception, handwashing practices, Nigeria.

48

49 Introduction

50

51 The Coronavirus infection (COVID-19) is an emerging infectious illness which broke out during
52 the winter of 2019 (Al-Hanawi et al, 2020; WHO, 2020). Due to its presentations, it has been
53 declared a public health emergency of international concern by the World Health Organization
54 (WHO) (WHO, 2020). An alarming response has been introduced across the globe due to its
55 high infectiousness and case fatality rate (Zhong et al., 2020). The identification of the risks and
56 the prevention of infectivity regarding COVID-19 have been stated to depend on human
57 perception (Zhong et al., 2020). Especially in the submergence of an infectious disease such as
58 COVID-19, different thoughts have shaped individuals' views on the illness.

59

60 Currently, the Coronavirus disease has spread to 213 countries with nearly 24 million confirmed
61 cases with close to 820,000 recorded deaths (WHO, 2020). Publicly available reports from the

62 Africa Centre for Disease Control (ACDC) states that confirmed cases of COVID-19 had risen to
63 1,203,769 and 28,289 deaths as of 25th of August 2020 (ACDC, 2020). As of 25th of August
64 2020, the West African subregion accounted for a significant proportion of cumulative COVID-
65 19 records in Africa. In Nigeria, there are 52,800 confirmed cases of COVID-19 with a total of
66 1007 deaths as of 25th of August 2020 (NCDC, 2020; WHO, 2020). Oyo State presently holds
67 the third spot on the Nigeria Centre for Disease Control (NCDC) daily COVID-19 updates, with
68 3058 laboratory-confirmed cases of COVID-19 and 37 deaths (NCDC, 2020). Urban areas in
69 Ibadan, the capital city of Oyo State frequently present with confirmed cases (Enwongo, 2020).

70

71 As a part of the emergency response activities across all States in Nigeria, health education
72 campaigns have been directed at members of the public (NCDC, 2020). These campaigns have
73 been aimed at knowledge improvement and the correction of certain misconceptions that have
74 been widely circulated among community members (NCDC, 2020) Education on precautionary
75 measures such as wearing of face masks, regular handwashing with soap and water or with
76 alcohol-based hand sanitizers, and social distancing have been done (NCDC, 2020; The Pace
77 Setter State, 2020).

78

79 It is evident that perception shapes one's knowledge and the adoption of safety measures
80 concerning the transmission of an infection. Data obtained from the perception of community
81 members regarding COVID-19 could help target interventions needed to improve the knowledge
82 of community members regarding Coronavirus. Superstitious beliefs have largely shaped the
83 perception of most Nigerians regarding the source and cause of COVID-19 (Chukwuorji & Iorfa,
84 2020). At the onset of the COVID-19 outbreak in Nigeria, infected persons belonged to either the
85 political class or high socioeconomic cadre (Chukwuorji & Iorfa, 2020). The characteristic
86 prevalence of COVID-19 infection among this group of persons accorded COVID-19 the name,
87 'a disease of the rich and mighty' (Nwaubani, 2020). Few months into the COVID-19 outbreak
88 in Nigeria, perceptions revolved around "immunity" to COVID-19 among the religious folks
89 with a disregard of bans on religious gatherings (Lichtensein, Ajayi, & Egbunike, 2020). Such
90 perceptions could have been influenced by several factors. Social media platforms such as
91 WhatsApp, Facebook, and Twitter have been used to spread false news on COVID-19, resulting
92 to panic disorder and anxiety among some persons and shunning of safety measures among

93 others (Aluh & Onu, 2020; Olapegba et al., 2020). Among many persons, physical distancing,
94 social isolations, restriction of religious and social gatherings etc. have been opined as alien
95 solutions in overcoming the COVID-19 pandemic in Nigeria and Africa at large (Olapegba et al.,
96 2020).

97
98 Literatures have reported the existence of knowledge relating to COVID-19 among Nigerians,
99 and it is expected that this would influence precautionary behavior among them. However,
100 inherent wrong perceptions may contribute to COVID-19 risk aversion measures (Iorfa et al.,
101 2020). Perceptions of COVID-19 has been influenced by age and gender. Due to their increased
102 vulnerability to illnesses, older persons have been predicted to increasingly adopt COVID-19
103 precautionary behavior compared to other population groups (Iorfa et al., 2020). Females have
104 been identified as models in the adoption of precautionary health behavior. In the COVID-19
105 context, the practice of handwashing, hygiene, and use of face masks occur more frequently
106 among females than males (Iorfa et al., 2020). Such an occurrence could be due to the perceived
107 susceptibility to illnesses among females as well as their health-conscious nature.

108

109

110 Given the importance of risk perception in behavior modification for disease control, it becomes
111 pertinent to assess the perception and practices regarding COVID-19. To the best of our
112 knowledge, the perception, and practices of community members in urban areas in Ibadan
113 regarding COVID-19 is currently unknown. An assessment of the perception and practices of
114 community members is important to reduce the risk for COVID-19 infection in Ibadan, a densely
115 populated city in Nigeria. We hypothesized that there is no difference in the sociodemographic
116 characteristics of the community members with the practices of COVID-19 mitigating factors.
117 This study thus aimed at assessing the perception and practices of community members in urban
118 areas in Ibadan regarding COVID-19.

119

120

121

122

123

124 **Materials & Methods**

125 **Study design and study setting**

126

127 A descriptive cross-sectional study design was used. Data was collected using an interviewer-
128 administered questionnaire. Data collection took place from the 3rd of June to the 6th of June
129 2020. The study was carried out in Ibadan, Oyo State Nigeria. Ibadan is the capital city of Oyo
130 State. Oyo State is one of the states in the south western part of Nigeria. Between 15th of June
131 and 10th of August, 2020, confirmed COVID-19 cases had risen from 764 to 2,887 in Oyo State,
132 and the State ranks next to Lagos State and the Federal Capital Territory on the NCDC reports
133 for COVID-19 (NCDC, 2020; Enwongo, 2020). The official language in Nigeria is English,
134 while the major informal language for communication in Ibadan is Yoruba, which has different
135 dialects.

136

137 **Study population**

138

139 The study population for the survey was one eligible member of the households in the selected
140 urban communities in Ibadan, Oyo State. All consenting household members were included in
141 the study. Household members that were less than 18 years were excluded. Verbal consent was
142 obtained from participants.

143

144 **Sample size determination and sampling technique**

145

146 The sample size was calculated using sample size formula for descriptive cross-sectional study.
147 The population of the selected LGA is >100,000. The sample size was calculated using the
148 Leslie Kish formula for sample size determination for a single proportion as follows:

149 $n = Z\alpha^2 p(1-p)/d^2$ where:

150 n = Minimum desired sample size

151 Z = the standard normal deviate, usually set as 1.96 which corresponds to 5% level of
152 significance.

153 P = 50% was be used

154 d = Degree of accuracy (precision) set at 5 % (0.05)

155 $n = 1.96^2 \times 0.5 \times (1-0.5) / 0.05^2 = 384$

156 A sample of 360 (93.8%) were studied in the urban communities of Ibadan. A multi-stage
157 sampling technique was used to select the respondents for the study

158

159 Stage 1:

160 Simple random sampling was used to select 3 out of the 6 urban local government area in Ibadan.

161

162 Stage 2:

163 In each of the selected LGA, a political ward was chosen for the study.

164

165 Stage 3:

166 A center location was chosen in the selected ward. A bottle was rotated to determine the
167 direction of movement of the interviewers. From the direction of the bottle tip all consenting
168 eligible adults from the households were included in the study until 120 persons were
169 interviewed in each LGA.

170 Sampling of 120 each in the three urban LGA gives a total sample size of 360.

171

172 **Data Collection Methods**

173

174 The questionnaire has two sections.

175 Section A: Sociodemographic characteristics

176 The sociodemographic characteristics include age of respondents, sex, highest level of education,
177 ethnicity, and occupation.

178

179 Section B: Perception and practices regarding COVID-19.

180 Close-ended questions were asked on perception of the respondents on COVID-19, their current
181 practices, and what they would do if they were infected. Open-ended questions were asked on
182 the effects of COVID-19 on and suggestions to the government to curb the pandemic.

183

184 A six-point question was asked on the practice of handwashing. The respondents were asked to
185 demonstrate how they usually practice handwashing. The interviewer correctly marked all the
186 points demonstrated by respondents.

187

188 The questionnaire was adapted from a tool used for a similar perception study on Ebola Virus
189 Disease in 2014 (Gidado et al., 2014). The tool was validated by an infectious disease
190 epidemiologist. Pre-testing of the tool was done by administering 10 questionnaires in another
191 Local Government Area not selected for the study. A few ambiguous questions were modified.
192 Back-to-back translation of the questionnaire was done by experts who had sound understanding
193 of the Yoruba language. The questionnaire was administered to most of the respondents in
194 Yoruba Language.

195

196 Data were collected using a semi-structured interviewer-administered questionnaire. The
197 questionnaire was used for a similar study done in Lagos Nigeria during the Ebola Virus Disease
198 outbreak (Gidado, 2014). A few adaptations were made to suit the COVID-19 context. Face
199 validity were done by a panel of expert epidemiologist. The questionnaire was pre-tested among
200 adult resident of an LGA that was not selected for the study (Ibadan South-West). Some
201 questions were modified based on the feedback received during pre-testing. Data collection was
202 done by trained research assistants with minimum of first degree.

203

204 Independent variables included: Sociodemographic characteristics like age, sex, level of
205 education, and occupation.

206 Outcome/dependent variables were the practice of handwashing and the use of other mitigating
207 measures.

208

209 **Data Management**

210

211 Data were analyzed with SPSS version 23. Age was summarized using mean and standard
212 deviation, while frequencies, and percentages were used for categorical variables. A total score
213 of 6 was assigned to good practice of hand washing after the respondents were asked to
214 demonstrate hand washing. One point each was assigned for the following: palm, back of the

215 hand, spaces between the fingers, fingernails, wrist and thumbs. Only those who demonstrated
216 the 6 points were categorized to have had a good practice of handwashing. Chi square test was
217 used for the assessment of associations between sociodemographic characteristics and practice of
218 handwashing. Pearson correlation was between the perception of likelihood to contract COVID-
219 19 and practices to prevent COVID-19. P value of < 0.05 were accepted as significant.

220

221 **Ethical Approval and Consent to Participate**

222

223 Ethical approval to carry out the study was obtained from the Oyo State Ministry of Health
224 Ethical Review Committee, with reference number AD/13/479/1779^A. Permission for the study
225 was sought from the respondents and their confidentiality was ensured. The respondents were
226 informed of their right to decline or withdraw from the study at any time without any adverse
227 consequences. No harm came to participants because of participation in this study.

228

229 **Results**

230

231 A total of 360 respondents were interviewed among urban residents in Ibadan. The mean age was
232 33.2 ± 10.6 years, among them 136 (37.8%) were aged between 25 and 34 years, and 225
233 (62.5%) were females. Those with secondary education and above were 332 (92.2%), 314
234 (87.2%) were of the Yoruba ethnic group, and 171 (47.5%) engaged in business or trading.
235 (Table 1). Among the 360 respondents 342 (95%) have heard of COVID-19.

236

237 Most frequently reported practices among respondents following the development of COVID-19
238 symptoms were: Going to the hospital 171(50%) and calling the COVID-19 help number 105
239 (30.7%). The other reported practices included: Praying and staying at home each with 29 (8.5%)
240 respondents as shown in Figure 1.

241

242 Regarding COVID-19, 89 (26%) knew they could contract COVID-19, while 41 (12%)
243 perceived it as an exaggerated event. It was also perceived as an intention for corruption by 23
244 (6.7%), COVID-19 was an attack by the Western World was reported by 68 (19,9%), and
245 122(35.7%) called COVID-19 a source of panic. The effects most frequently reported by

246 respondents were hunger/low income 167 (48.8%) and academic delay 30 (8.8%). Regarding
247 suggestions to the government, 108 (31.6%) suggested the provision of medical
248 supplies/palliatives/ seeking of cure, while 68 (19.9%) suggested free testing/free treatment.
249 Other effects of COVID-19 and suggestions to the government are as shown in Table 2.

250

251 The most frequently reported practice for prevention of COVID-19 among respondents were the
252 use of face masks by 224 (65.5%) and social distancing by 164 (48%). Others included: Staying
253 at home/following COVID-19 updates 8 (2.2%), taking Vitamin C/fruits/warm water 4 (1.1%),
254 and doing nothing 5 (1.4%) as shown in Figure 2.

255

256 Figure 3 shows that only 80 (22%) of respondents demonstrated good handwashing practices.
257 Among respondents aged less than 25 years, 16 (23.5%) had good handwashing practice
258 compared to 14(29.8%) aged above 45 years. Among females, 49 (22.8%) had good
259 handwashing practices compared to 22(17.3%) males although these differences are not
260 statistically significant (Table 3).

261

262 Males have 27.5% less odds of having good hand washing practice compared to females, though
263 not statistically significant [AOR 0.725,95%CI=0.418-1.259, p=0.253], (Table 4).

264

265 The perception of the likelihood to contract COVID-19 and practices to prevent COVID-19 had
266 a weak positive correlation of 0.239($p<0.001$).

267

268 Discussion

269

270 This study found that many individuals lived in denial of the existence of COVID-19. The
271 perception of the illness as an avenue for politicians to enrich themselves indicates that there still
272 exists inadequate knowledge of the Coronavirus among community members in Ibadan. Denial,
273 ignorance regarding COVID-19, and the existing lack of trust in the Nigerian government have
274 been reported since the outbreak of COVID-19 in Nigeria (Chukwuorji & Iorfa, 2020). From the
275 present study, a high rating of the perceived likelihood of contracting COVID-19 was observed

276 among 26% of respondents, while it was minimally perceived as an attack by the Western World
277 among nearly 20%.

278

279 Findings obtained from this study revealed that the practices most often adopted following the
280 development of COVID-19 symptoms were either to go to the hospital or call the COVID-19
281 help number. This indicates that the source of help for COVID-19 treatment is well known
282 among community members in urban areas of Ibadan. Although distrust in government capacity
283 regarding COVID-19 is currently obtainable, individuals are willing to take proactive measures
284 following the suspected development of COVID-19 symptoms (Chukuorji & Iorfa, 2020). An
285 Indian study similarly reported that hospital visitation was frequently opted for as a step to be
286 taken following the development of COVID-19 in individuals in a close relationship (Dkar et al.,
287 2020).

288

289 We found that about the use of face masks and practice of social distancing measures were more
290 frequently embraced among respondents compared to other COVID-19 mitigation measures,
291 although full adherence was low. A web-based study conducted in Nigeria mostly stated mouth-
292 covering while sneezing, wearing of face masks, and avoidance of crowded spaces as self-
293 reported practices among respondents (Iorfa et al., 2020). Our findings revealed that myriads of
294 perceptions were associated with COVID-19. These included COVID-19 as an exaggerated
295 illness with intentions for corruption, its highly infectious and deadly nature, and a reason for
296 panic disorders. Similarly, the likelihood of positive practices concerning COVID-19 was
297 associated with a positive perception of the risk of infection (Zhong et al., 2020). Findings from
298 previous studies conducted in Nigeria also corroborate the key role of positive risk perception on
299 imbibing COVID-19 protective practices and attitudes (Iorfa et al., 2020). The finding from the
300 present study contradicts the assumption of the Health Belief Model (HBM) that protective
301 actions are more likely to succeed a high level of perceived susceptibility (Tarkang et al., 2015).
302 The results obtained herein is higher than the knowledge concerning the practice of face masks
303 in Saudi Arabia (Al-Hanawi et al., 2020). Due to its deadly nature, COVID-19 has introduced
304 fear which has compelled protective actions from individuals regarding the illness (Zhong et al.,
305 2020).

306

307 Previous studies have shown that fear could motivate healthy behavior among individuals
308 especially during epidemics, but such behavior may not be sustainable (Witte, 1998; Nabi, 1999;
309 Ufuwa et al., 2020). The adoption of these healthy behaviors in the present study is in tandem
310 with the recommendations of the World Health Organization (WHO) on safety measures for
311 COVID-19 (WHO, 2020). The insufficiency of fear as a propellant for adherence to
312 recommended guidelines for COVID-19 has been reported to be an outplay of knowledge-
313 attitude discrepancy (Iorfa et al., 2020). These findings imply that individual perception of
314 infectious illnesses such as COVID-19 may not be sufficient to influence the adoption of
315 protective practices. This explains the need for a regular sensitization of community members on
316 COVID-19 safety measures regardless of their perception concerning the illness.

317

318 We found that the practice of handwashing was commoner among individuals with a greater risk
319 perception for COVID-19. Because these individuals perceive themselves as vulnerable to
320 COVID-19 infection, they are more likely to engage in handwashing practice. Handwashing
321 practice has been identified as one of the mitigation strategies for breaking the chain of COVID-
322 19 transmission. An online-based Nigerian survey revealed a higher practice of handwashing
323 compared to other COVID-19 preventive measures (Iorfa et al., 2020). A study conducted in
324 Ibadan on hand hygiene practices post Ebola virus disease outbreak revealed a high proportion of
325 inadequate self-reported hand hygiene practice (Martins & Osiyemi, 2017). Lassa fever studies
326 conducted in Edo State reported inadequate handwashing practices, while a similar study in
327 Kaduna State, Nigeria reported good handwashing practices among respondents (Tobin et al.,
328 2019;). The similarities of most of these findings with ours imply the wide acceptance of the
329 practice of handwashing in the management of infectious diseases.

330

331 We found that COVID-19 poses significant threat to local economy, resulting in low income and
332 resultant hunger. This is likely due to the increased cost of purchasing goods or a result of the
333 lockdown which has denied many individuals the opportunity to earn their income. Denial of
334 opportunities to engaging in money-making ventures was experienced and impacts such as
335 hunger was greatly felt among many persons (Chukwuorji & Iorfa, 2020). This explains the need
336 for the provision of palliatives to fight hunger and reduce susceptibility to other infections during
337 the COVID-19 outbreak. Similarly, decreased productivity and job losses and an unprecedented

338 economic disaster have been reported (Atalan, 2020). Contrary to the finding in this study, other
339 studies have reported stress and anxiety as psychological reactions due to the Coronavirus
340 pandemic (Atalan, 2020). Other psychological reactions such as boredom, anger, and loneliness
341 have been notably identified as resultant threats during the COVID-19 pandemic (Aluh & Onu,
342 2020). This calls for the provision of psychosocial support for individuals during the COVID-19
343 lockdown. Interestingly, a recognition of the significance of essential staff has also resulted from
344 the COVID-19 outbreak (The National, 2020).

345

346 Pertaining to suggestions to the government concerning COVID-19 containment, the provision
347 of medical supplies and palliatives received highest recommendation among respondents. Most
348 Nigerian households depend on daily earnings of breadwinners, and difficulty in survival was
349 experienced during the COVID-19 lockdown which lasted for three months in Nigeria
350 (Chukwuorji & Iorfa, 2020). Also, health education, the enforcement of preventive measures,
351 and free testing and treatment received much recognition. These imply two things. Firstly, health
352 education concerning COVID-19 should be done by public health officials in simple,
353 unambiguous languages which will facilitate the understanding of community members.
354 Secondly, the availability of medical supplies and palliatives would enhance the adherence to
355 safety measures for COVID-19, such as the use of face masks among community members.
356 Similar suggestions have been made in previous studies (Kebede et al., 2020)

357

358 **Strengths of the Study**

359

360 Up to date, most studies on perception and practices regarding COVID-19 have used electronic
361 sources for data collection, and such results may have been biased. Our study is a community-
362 based physical study that used a semi-structured interviewer-administered questionnaire. To the
363 best of our knowledge, it is the first to study the perception and practices of adult population in
364 urban communities in Nigeria. The study also made use of a adequate sample size (360 adults).

365

366 **Limitations of the Study**

367

368 As this study was limited to the perception and practices regarding COVID-19, the knowledge of
369 community members on the illness was not addressed. The assessment of factors influencing
370 COVID-19 practices among community members was obscure in this study.

371

372 **Conclusions**

373

374 The adoption of preventive measures depends on an individual's perception of the risk of an
375 illness. Adequate and correct risk perception for COVID-19 is needed to forestall onward
376 transmission of COVID-19. We hereby recommend enhanced sensitization and health education
377 sessions for all community members about COVID-19 in Ibadan metropolis regardless of their
378 sociodemographic characteristics. Also, health campaigns should be more focused on practices
379 such as regular handwashing with soap and water, physical and social distancing, which protect
380 against transmission of COVID-19.

381

382 **Acknowledgements**

383 The authors express their gratitude to all community members for their willingness and
384 cooperation to participate in this study.

Points scored in handwashing demonstration

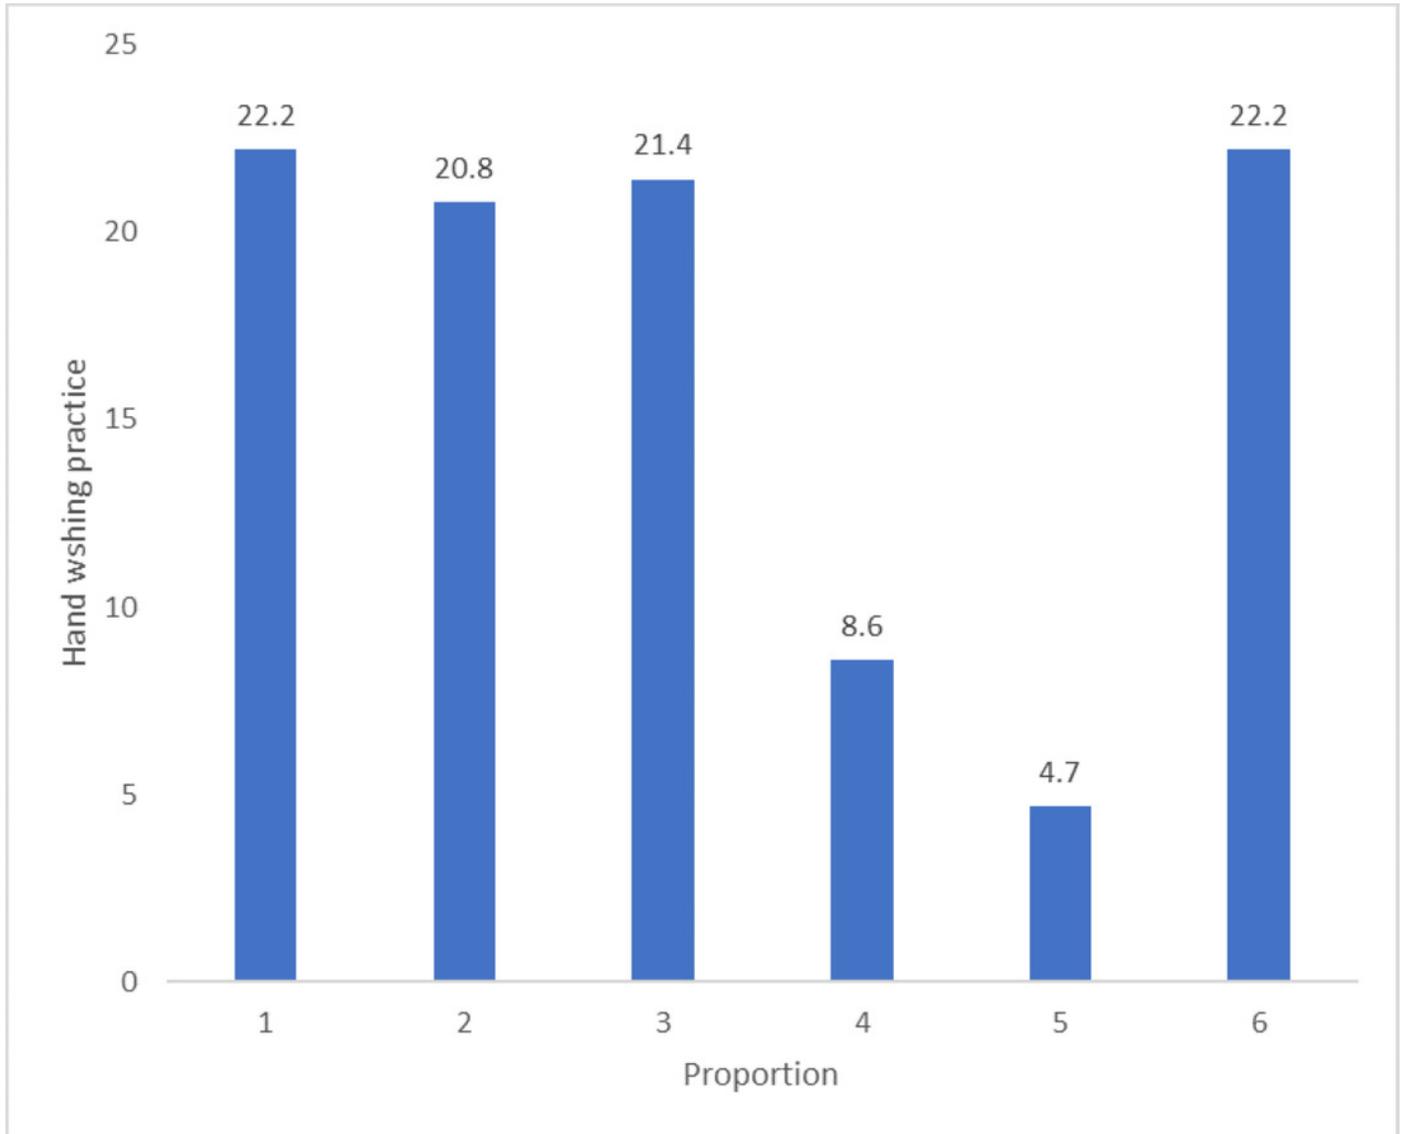

Table 1 (on next page)

Sociodemographic characteristics of respondents among Ibadan residents, 2020

1

Socio-demographic Characteristics	Frequency	%
Age group (Years)		
<25	70	19.4
25-34	136	37.8
35-44	106	29.4
≥45	48	13.3
Sex		
Male	135	37.5
Female	225	62.5
Highest level of Education		
Primary and below	28	7.8
Secondary and above	332	92.2
Ethnicity		
Yoruba	314	87.2
Ibo	31	8.6
Hausa	8	2.2
Others	7	1.9
Occupation		
Business/Trader	171	47.5
Artisans	110	30.6
Professional/Civil Servant	30	8.3
Unemployed/housewife/student	49	13.6

2

Table 2 (on next page)

Perceptions and effects of COVID-19 and suggestions to government by community members in Ibadan, 2020

1

Variables	n (%)
Perception on COVID-19	
It creates a lot of panic	122 (35.7)
It is a deadly disease	94 (27.5)
I am at risk of COVID-19 infection	89 (26)
It is highly infectious	72 (21.1)
It is an attack by the Western World	68 (19.9)
It is just being exaggerated	41 (12)
It has no cure	33 (9.6)
Don't believe it exists	28 (8.2)
An intention for corruption	23 (6.7)
Effects of COVID-19	
Hunger/Low income	167 (48.8)
Academic delay	30 (8.8)
Restricted movement/No going to work	25 (7.3)
No gatherings	20 (5.8)
Suggestions to Government	
Provide medical supplies/Palliatives/Seek cure	108 (31.6)
Health Education/Enforce preventive measures	70 (20.5)
Free testing/Free treatment	68 (19.9)
Stop reporting false figures/Lift lockdown and bans	44 (12.9)
No idea/Do anything	27 (7.9)
