Abstract

Burmese Cretaceous amber (~99 Ma, Myanmar) is famous for the preservation of a wide
range of fauna and flora, including representatives of marine, freshwater and terrestrial groups.
Here, we report on three ostracod specimens, that came visible as syninclusions to an aquatic
isopod. The three specimens represent three different taxa, that were found preserved in a single
piece of amber. One of the described specimens was studied using µCT scanning data. On the
basis of general carapace morphology we assign all three to the group Podocopida, and
(tentatively) its ingroup Cypridocopina. A lack of visibility of more particular diagnostic features
such as adductor muscle scars and details of the marginal zone precludes a further identification,
but we discuss possible affinities with either the marine-brackish group Pontocypridoidea or the
non-marine group Cypridoidea. The taphonomy indicates that the studied ostracods had been
subject to limited (if any) post-mortem transport, which could be consistent with marginal
marine environments.

Keywords. Myanmar, amber, ostracods, palaeoenvironment, taphonomy

Introduction

Ostracods (also known as "seed shrimps") are small crustaceans with a bivalved carapace
(e.g., *Horne et al.*, *2002*). Adult ostracods are typically 0.5–2 mm long, but can also be smaller
or much larger, for example the marine *Gigantocypris* can be more than 30 mm (*Poulsen, 1962*;
Horne et al., *2002*; *Brusca & Brusca, 2003*). Ostracods are the most commonly preserved fossil

40   arthropods, which can be dated back to Early Ordovician (*Horne*, *2005*). The earliest ostracods
41   are all marine and the first undoubted non-marine representatives of the group are of Early
42   Carboniferous age (*Rodriguez-Lazaro & Ruiz-Muñoz*, *2012*). At the present day, non-marine
43   ostracods can be found in most non-marine aquatic ecosystems including freshwater and saline
44   lakes, streams and rivers, springs, wetlands, temporary ponds, and groundwater (*Horne et al.*,
45   *2019*). They can even be found in semi-terrestrial habitats such as moist soils with leaf litter
46   (*Rodriguez-Lazaro and Ruiz-Muñoz*, *2012*). However, most of the relatively few records of
47   ostracods preserved in amber (e.g., *Keyser & Weitschat, 2005*; *Keyser & Friedrich*, *2017*;
48   *Matzke-Karasz et al.*, *2019*) are from the Cenozoic and, although the number of kinds of
49   organisms trapped in Burmese Cretaceous amber from Myanmar has increased exponentially
50   over the past few years (including flowers, fungi, scorpions, spiders, crabs, frogs, dinosaurs and
51   insects; *Ross*, *2018*), only one ostracod (a marine myodocopan) has so far been reported (*Xing et
52   al.*, *2018*). Here, we report podocopan ostracods from amber of Myanmar ("Burmite"), the age of
53   which has been biostratigraphically constrained to be late Albian–early Cenomanian (latest Early
54   to earliest Late Cretaceous; *Cruickshank & Ko*, *2003*). *Shi et al.* (2012) further constrained the
55   age geochronologically based on U-Pb zircon ages from the volcanoclastic rock matrix,
56   containing the amber, to lowermost Cenomanian, ~ 99 million years. In this study we describe
57   three fossil remains of Ostracoda in Burmese amber along with a careful interpretation about
58   their systematic position and critically discuss their values as palaeoenvironmental indicators.
59

Materials & Methods

61   A single piece of amber (26.4 mm feret diameter) is the focus of this study. It was
62   commercially obtained by Mark Pankowski (Rockville, Maryland, USA) and was donated to the
63   collection of the Natural History Museum Vienna ("Naturhistorisches Museum Wien", NHMW)
64   in April 2017 (Thomas Nichterl, collection manager at NHMW, pers. comm., 2020). The amber
65   piece is available under the collection number NHMW-2017/0052/0001. The amber piece comes
66   from one of the commercial mining sites in the Hukawng Valley in the Kachin Province of
67   Myanmar (Haug et al., 2020). Due to being commercially acquired, stating a more precise
68   provenance is not possible.
69   Microscopic images were made using a Keyence VHX-6000 digital microscope. The focus-
70   stacking function of the digital microscope was used to create in-focus images of three-
71   dimensional objects despite the limitation of the depth-of-field. To gather x-ray micro-computer
72   tomography (µCT) data, a Baker Hughes (General Electrics) "phoenix nanotom m" computer
73   tomograph was used along with the acquisition software "datos|x". The µCT imaging was
74   performed at the zoological State collection in Munich. A current of 100 kV was used to scan the
75   object. The amber piece was rotated 360 degrees in 1440 steps. The final reconstruction of the
76   volume data was done using VGStudio MAX 2.2.6.80630 (Volume Graphics). The achieved
77   voxel size of the volume was 2.81295 µm. Drishti 2.6.4 (GNU) was used for volume rendering.
78   In some cases, more than one transfer function was applied to show structures with different x-
79   ray qualities. Regular (two-dimensional) images and red-cyan stereo anaglyphs were exported.

80   GIMP 2.10 (GNU) was used to optimize the histogram, and enhance colour, brightness and
81   contrast of the final images. Inkscape (versions 0.92.3 and 0.92.4, GNU) was used to create the
82   figure plates. Measurements were performed using ImageJ (FIJI, public domain).
83
84   **Systematic palaeontology**
85   The higher classification draws mainly on schemes published by *Horne* (2002), *Hou et al.* (2002)
86   and *Smith et al.* (2015).
87
88   Ostracoda Latreille, 1806 (= Ostrachoda Latreille, 1802)
89   Podocopa Sars, 1866
90   Podocopida Sars, 1866
91   Cypridocopina Jones, 1901
92
93   All three ostracod taxa are assigned to the Cypridocopina on the basis of their overall carapace
94   morphology, including rounded subtriangular outline in lateral view, compressed fusiform
95   outline in dorsal/ventral view, and smooth or lightly pitted external surface. Neither with light
96   microscopy nor with computer-tomography have we been able to resolve any diagnostic features,
97   such as adductor muscle scars or internal details of the marginal zone, that might lead to a more
98   precise identification.
99
100   Taxon A
101   Fig. 1A; Fig. 2; Suppl. 1
102
103   Material. One articulated carapace, moderately well preserved.
104
105   Dimensions. L: 0.57 mm, H: 0.34 mm, W: 0.17 mm.
106
107   Locality and horizon. Hukawng Valley, Kachin Province, Myanmar (E 96°36′15″, N 26°13′47″,
108   accuracy of about 10 km); lowermost Cenomanian, lowermost Upper Cretaceous.
109
110   Description. Carapace small, elongate subtriangular in lateral view; slender, fusiform (spindle-
111   shaped) with bluntly rounded extremities in dorsal view. Left valve slightly larger than right
112   valve and overlapping right valve along all margins but most markedly on the ventral margin and
113   at the highest point of the dorsal margin. Left valve possibly with alveolus behind a rostrum.
114   Maximum height at one third of length from anterior margin. Anterior cardinal distinct, obtuse-
115   angled (approx. 140°), forming the highest point. Posterior cardinal angle weakly rounded and
116   obtuse with about 160°. Anterior margin broad and slightly infracurvate, almost equicurvate with
117   a moderately long, nearly straight dorsal part. Posterior margin distinctly narrower than anterior
118   one, rounded and equicurvate, having a short slightly curved dorsal part. Dorsal margin slightly

119 convex and inclined towards posterior end, about 20°. Ventral margin almost straight, slightly
120 concave at mid-length. Surface smooth. Internal features not observable.
121
122 Remarks: The left valve shows shallow indentation near the anterior end of the ventral margin
123 that could be interpreted as an alveolus behind a rostrum, i.e. a "beak" such as is diagnostic of
124 the group *Cypridea* (Superfamily Cypridoidea) (Fig. 2H). However, there is no trace of its
125 equivalent in the left valve, and the feature may actually represent damage to the valve. Based on
126 the gross morphological similarities, taxa A belongs to either Pontocypridoidea or Cypridoidea.
127 However, the strong asymmetry of the right and left valves perhaps favours an assignment to the
128 group Cypridoidea but this is not conclusive.
129
130 Taxon B
131 Fig. 1B
132
133 Material. One articulated carapace, well-preserved.
134
135 Locality and horizon. Hukawng Valley, Kachin Province, Myanmar (E 96°36′15″, N 26°13′47″,
136 accuracy of about 10 km); lowermost Cenomanian, lowermost Upper Cretaceous.
137
138 Description. Carapace small and fusiform (spindle-shaped) with sharp extremities in dorsal view;
139 surface smooth. Valves approximately equal in size, without evident overlap. Internal features
140 not observable.
141
142 Remarks: We have been unable to obtain a clear lateral view of this carapace, which appears to
143 differ from those of taxa A and C by having sharper anterior and posterior extremities and no
144 obvious overlap of the valves. We speculate that Taxon B belongs to either Pontocypridoidea or
145 Cypridoidea according to preserved features.
146
147 Taxon C
148 Fig. 1C
149
150 Material. One articulated carapace, well-preserved.
151
152 Locality and horizon. Hukawng Valley, Kachin Province, Myanmar (E 96°36′15″, N 26°13′47″,
153 accuracy of about 10 km); lowermost Cenomanian, lowermost Upper Cretaceous.
154
155 Description. Carapace small, rounded subtriangular in lateral view. Left valve slightly
156 overlapping right valve along ventral and posterior margins. Maximum height in front of mid-
157 length. Anterior margin broad, almost equicurvate. Posterior margin narrower than anterior one,
158 rounded and equicurvate. Carapace distinctly punctate tending to reticulation. Internal features
159 not observable.

160

161   Remarks: The carapace is similar in lateral outline, but laterally more inflated, than that of Taxon
162   A. Moreover, Taxon A has an apparently smooth exterior while Taxon C is distinctly punctate.
163   Based on its overall shape and distinct punctation it has strong similarities to species of the non-
164   marine group *Harbinia* Tsao, 1959 (an ingroup of Cypridoidea).

165

166   Syninclusions: cf. Psychodidae (Diptera); *Alavesia* sp. (Diptera); Coleoptera sp.; Euarthropoda
167   sp. (one unidentifiable remain and three isolated legs); *Cymothoida* sp. (Isopoda) (Schädel et al.
168   in review).

169

170   Discussion

171   Even though the studied ostracod specimens are well-preserved, their positions within the
172   amber piece do not allow us to study further details, so we are unable to identify them beyond
173   suborder level with confidence. This limitation in turn impedes the palaeoenviromental
174   interpretation of the assemblage. Nevertheless, we can speculate, on the basis of gross
175   morphological similarities, that at least taxa A and B belong to either of two ingroups of
176   Cypridocopina, namely Pontocypridoidea and Cypridoidea. Moreover, as we don't know if the
177   specimens are adults, and the shape of Taxon A could be a juvenile, which tend to have less
178   inflated posterior margins. If we assume Taxon A is an adult, then it resembles a
179   Pontocypridoidea or Cypridoidea (maybe even a Paracypridinae of the Candonidae).
180   Cypridoidea are the predominant group in non-marine environments today, such as fresh water
181   and saline inland water (athalassic environments). Pontocypridoidea, on the other hand,
182   comprises marine and brackish-water taxa (*Horne, 2003*). In the case of Taxon C the general
183   shape and the association with the other two taxa suggest that it, too, is a cypridocopine. Species
184   of the Cretaceous non-marine cypridoidean genus *Harbinia* Tsao, 1959, have similar carapace
185   shape and punctate/reticulate ornament (e.g. *Harbinia hapla* Tsao, 1959, illustrated by *Ye et al.*
186   (2003: pl. 27, figs 2a-c). However, we cannot rule out the possibility that it may belong to the
187   group Cytheroidea (which is the dominant marine group today but also has non-marine lineages)
188   without being able to see the characteristic adductor muscle scar patterns that distinguish
189   between cypridoideans and cytheroideans.
190   All three ostracod specimens in this study lack preserved soft parts but are preserved with
191   articulated carapaces, suggesting limited (if any) post-mortem transport. In view of our
192   uncertainty about the precise systematic interpretation of our specimens we can contribute little
193   to the discussion of the taphonomic and palaeoenvironmental interpretation of the Burmese
194   amber assemblage. Both cypridoidean and pontocypridoidean taxa would be consistent with the
195   mixed marine–freshwater–terrestrial components of the assemblage.
196   An ammonite shell preserved in Burmese amber argues that the Burmese amber forest was
197   located near a dynamic and shifting coastal environment (*Yu et al., 2019*), a conclusion
198   supported by the occurrence of a marine myodocopan ostracod (*Xing et al., 2018*). Also, semi-
199   aquatic and aquatic insects occur in Burmese amber, including Ochteridae (Hemiptera),

200 Heteroceridae (Coleoptera), Chresmododea and Gerridae (Hemiptera), Dytiscidae and Gyrinidae
201 (Coleoptera), adults and larvae of Odonata, larvae of Psephenidae, Trichoptera, and
202 Ephemeroptera (*Zhang, 2017*; *Xing et al., 2018*; *Schädel et al.*, 2020). The herein presented
203 ostracods are within the same amber piece as a fossil, supposedly aquatic living, isopod (*Schädel*
204 *et al.* in review). Actuo-palaeontological experiments (*Schmidt & Dilcher*, 2007) have
205 demonstrated, that it is easily possible for aquatic organisms to be trapped in submerged bodies
206 of resin. Several records of delicate arthropod remains from groups with supposed aquatic
207 lifestyle (*Heard et al., 2018*; *Schädel et al., 2019*; *Schädel et al. 2020*; *Serrano-Sánchez et al.*,
208 *2015*; *Serrano-Sánchez et al., 2016*) indicate that the result of in-situ embedment of aquatic
209 organisms is present in many amber sites. Recurrent flows of resin and changing water levels can
210 explain the preservation of aquatic and non-aquatic organisms – such as the dipterans in the
211 herein presented assemblage – in the same amber piece (*Xing et al., 2018*).
212

Conclusions

214 The three specimens are new records of podocopan ostracods to be reported from Burmese
215 Cretaceous amber, and most likely belong to the Order Podocopida, Suborder Cypridocopina,
216 and either the Superfamily Cypridoidea (indicative of non-marine environments) or the
217 Superfamily Pontocypridoidea (indicative of marine/brackish environments). If the former be
218 true, these would be the oldest non-marine ostracods preserved in amber. Either superfamily
219 assignment would be consistent with previous evidence of a mixed marine–freshwater–terrestrial
220 assemblage deposited in a coastal setting.
221

Acknowledgements

223 Our greatest gratitude is to Mark Pankowski who generously donated the amber piece to the
224 Natural History Museum in Vienna. We thank Matúš Hyžný and Mathias Harzhauser for
225 mediation and access to the amber piece. We are grateful to Roland Melzer (Zoological State
226 Collection, Munich) for his help with the µCT scans. Viktor Baranov (LMU, Munich) is thanked
227 for his help with the identification of the syninclusions. BS acknowledges support from Austrian
228 Science Fund (FWF) project P 27687-N29. MS is kindly funded by the Deutsche
229 Forschungsgemeinschaft (DFG Ha 6300/3-2) and thanks Joachim T. Haug and Carolin Haug
230 (both LMU, Munich) for their enormous support. For constructive suggestions regarding the
231 manuscript we thank the editor (Kenneth De Baets), Alan Lord and one anonymous reviewer.
232 This research was supported by the Strategic Priority Research Program of the Chinese Academy
233 of Sciences (XDB26000000). Furthermore, we are thankful to the various contributors of the free
234 and open source software used in this study.

235

Data and materials availability:

237 The amber is deposited permanently at the Natural History Museum Vienna (Naturhistorisches
238 Museum Wien', NHMW) in full compliance with the International Code of Zoological
239 Nomenclature (https://www.iczn.org/the-code/the-international-code-of-zoological-

240 nomenclature/the-code-online/). The fossils at the NHMW are held safely in trust for the benefit
241 of researchers and educators in the world respecting all ethnic groups, ages, sexes, landowners
242 and collectors. Apart from public exhibitions, access is free to all scientists and interested people
243 by prior arrangement during normal working hours and subject to the NHMW laboratory and
244 museum regulations. All data needed to evaluate the conclusions in the paper are present in the
245 paper. All data related to the paper are also deposited in the Morph·D·Base (Zoological Research
246 Museum Alexander Koenig, Germany). Correspondence and requests should be addressed to
247 H.W.

344   Figure explanations

345

346   Fig. 1: A: Overview image depicting the relative position of the ostracods (white arrows); B:

347   Taxon B with numerous vesicles at or right above the lateral pore canals; C: overview image of

348   the amber piece. D: Taxon C; asterisk: Taxon A.

349

350   Fig. 2: Taxon A. A−B: light microscopy, mixed translucent and reflected light. A: dorsolateral

351   view. B: left lateral view, side 1; C–L: volume rendering images based on μCT data. C: right

352   lateral view; D: red-cyan stereo anaglyph, posterolateral view; E: posterior view; F: ventral view;

353   G: dorsal view; H: left lateral view; I: red-cyan stereo anaglyph, anterolateral view; J: anterior

354   view; K: ventral view, presumed pyrite crystals in red; L: right lateral, presumed pyrite crystals

355   in red.

Figure 1

Fig. 1: A: Overview image depicting the relative position of the ostracods (white arrows);
B: Taxon B with numerous vesicles at or right above the lateral pore canals; C: overview
image of the amber piece. D: Taxon C; asterisk: Taxon A.

Figure 2

Taxon A. A−B: light microscopy, mixed translucent and reflected light. A: dorsolateral view. B: left lateral view, side 1; C–L: volume rendering images based on μCT data. C: right lateral view; D: red-cyan stereo anaglyph, posterolateral view;

E: posterior view; F: ventral view; G: dorsal view; H: left lateral view; I: red-cyan stereo anaglyph, anterolateral view; J: anterior view; K: ventral view, presumed pyrite crystals in red; L: right lateral, presumed pyrite crystals in red.
