Background. The practice of feeding a raw meat-based diet (RMBD) to dogs is a topic of increasing interest to owners and veterinary professionals alike. Despite the research around the practice, particularly about the risk of nutritional imbalances and microbial contamination, an increasing number of dog owners are adopting a raw diet for their dogs. This study expands the research into owner motivations for feeding RMBDs and cooked diets and asks them their opinions about risk and nutritional value.

Methods. An anonymized, online, internationally accessible questionnaire was developed to ascertain owner perspectives on the risks, benefits, and nutritional value of commercially prepared and homemade RMBDs as compared with commercially prepared cooked diets (CCDs).

Results. The questionnaire was completed by 419 dog owners of diverse backgrounds across the world. Of the participants, 25.3% fed RMBDs. Just over 70.0% of all participants had spoken to their veterinarian about their dog's nutrition. Owners who fed RMBDs ranked their veterinarian's knowledge lower and their own knowledge of canine nutrition higher than owners who fed CCDs. They rated commercial and homemade RMBDs as highly nutritious 83.5% and 73.6% of the time, respectively, while only 12.5% rated CCDs as highly nutritious. Owners who fed CCDs ranked RMBDs as highly nutritious less often, but also only ranked CCDs as highly nutritious 52.7% of the time. All participants agreed that CCDs were low risk to human health. Owners who fed RMBDs ranked raw diets as highly risky to human or dog health under 20.0% of the time but deemed CCDs risky to animal health over 65.0% of the time. When asked about benefits of raw diets, the most repeated words offered by owners were "health", "better", "coat" and "teeth". The most repeated risks presented were "bacteria", "nutrition", "risk" and "Salmonella". Owners who fed RMBDs tended to use vague terminology like "health" and "better" when asked why they fed a raw diet. Owners who did not feed RMBDs used more specific terminology like "expensive", "time" and "risk" when asked why they did not feed a raw diet. Overall, the two groups differed in their perceptions around RMBD and CCD feeding, which highlights the need for a better line of communication and education between veterinarians and owners.

Abstract

12 **Background.** The practice of feeding a raw meat-based diet (RMBD) to dogs is a topic of
13 increasing interest to owners and veterinary professionals alike. Despite the research around
14 the practice, particularly about the risk of nutritional imbalances and microbial
15 contamination, an increasing number of dog owners are adopting a raw diet for their dogs.
16 This study expands the research into owner motivations for feeding RMBDs and cooked
17 diets and asks them their opinions about risk and nutritional value.
18 **Methods.** An anonymized, online, internationally accessible questionnaire was developed to
19 ascertain owner perspectives on the risks, benefits, and nutritional value of commercially
20 prepared and homemade RMBDs as compared with commercially prepared cooked diets
21 (CCDs).
22 **Results.** The questionnaire was completed by 419 dog owners of diverse backgrounds across
23 the world. Of the participants, 25.3% fed RMBDs. Just over 70.0% of all participants had
24 spoken to their veterinarian about their dog's nutrition. Owners who fed RMBDs ranked their
25 veterinarian's knowledge lower and their own knowledge of canine nutrition higher than
26 owners who fed CCDs. They rated commercial and homemade RMBDs as highly nutritious
27 83.5% and 73.6% of the time, respectively, while only 12.5% rated CCDs as highly
28 nutritious. Owners who fed CCDs ranked RMBDs as highly nutritious less often, but also
29 only ranked CCDs as highly nutritious 52.7% of the time. All participants agreed that CCDs
30 were low risk to human health. Owners who fed RMBDs ranked raw diets as highly risky to
31 human or dog health under 20.0% of the time but deemed CCDs risky to animal health over
32 65.0% of the time.
33 When asked about benefits of raw diets, the most repeated words offered by owners were
34 "health", "better", "coat" and "teeth". The most repeated risks presented were "bacteria",
35 "nutrition", "risk" and "Salmonella". Owners who fed RMBDs tended to use vague
36 terminology like "health" and "better" when asked why they fed a raw diet. Owners who did
37 not feed RMBDs used more specific terminology like "expensive", "time" and "risk" when
38 asked why they did not feed a raw diet. Overall, the two groups differed in their perceptions
39 around RMBD and CCD feeding, which highlights the need for a better line of
40 communication and education between veterinarians and owners.
41

Introduction

43 The practice of feeding a raw meat-based diet (RMBD) to dogs is a topic of increasing interest to
44 owners and veterinary professionals alike, with Google searches for 'raw dog food' quadrupling
45 over the last ten years.[1] Estimates of the percentage of dog owners who feed RMBDs vary, but
46 experts agree that the practice is increasing in both the United States and Europe.[2]
47
48 As the feeding of RMBDs has become more common there has been an increase in research on
49 the safety of the practice, particularly the potential for nutritional imbalances and the
50 microbiological risks associated with raw meat. Leading veterinary organizations, from the
51 American Veterinary Medical Association to the World Small Animal Veterinary Association,
52 discourage the feeding of RMBDs, but given its increasing popularity, some owners are clearly
53 not heeding their warnings.[3,4] Despite this increased popularity and interest in RMBDs, scant

54 research has been published on dog owner opinions regarding this type of feeding and comparing
55 it to the feeding of commercially prepared cooked diets (CCDs).
56
57 This study was undertaken with the aim to better understand dog owner perspectives on risks,
58 benefits, and nutritional value of raw diets compared to cooked diets. We hypothesized that
59 owners who feed primarily raw diets to their dogs will perceive the practice to pose less risk to
60 both human and animal health than those who feed a non-raw diet. We also anticipated that those
61 who feed raw diets will perceive them as more or equally nutritious as CCDs.
62

Materials & Methods

64 Approval to conduct the project was sought and granted by the University of Glasgow College of
65 Medical, Veterinary & Life Sciences Ethics Committee for Non-Clinical Research Involving
66 Human Participants (Approval Ref: 200180125).
67
68 An anonymized, online, internationally accessible, open questionnaire was developed using
69 Google Forms. The questionnaire was tested against peers to assess usability, technical
70 functionality, comprehension, cohesiveness, flow, and length before fielding the study. The
71 questionnaire consisted of 11 sections. The first section included a description of the
72 questionnaire including time estimate for completion, stated the terms of consent, and included
73 contact information for the researchers. Any person over the age of 18 who was the primary
74 owner or caregiver of a pet dog was invited to participate as the target population. Participation
75 was completely voluntary and required participants to consent to continue with the questionnaire.
76 Participants were not required to sign in or belong to any network in order to participate. No
77 incentives for participation were offered. The second section collected demographics about the
78 dog owner. Sections 3-10 included dichotomous, categorical, ordinal and free-text box questions.
79 Sections 3-10 included 1-4 questions each, with an average of 3 questions per section. Section 11
80 consisted of a brief appreciation for their time and ended the questionnaire. Participants were
81 allowed to skip any question or answer free-text questions with "NA" (not applicable) and they
82 were able to navigate forwards and backwards before submitting the questionnaire. Questions
83 asked about general feeding trends and opinions, rather than asking for owners to respond about
84 each pet they may own.
85
86 Results were automatically collected by the Google Forms software and were exported from the
87 internet when the data collection was finished.
88
89 After obtaining permission from page administrators, a live, sharable link to the questionnaire
90 was initially posted four times on dog-centric community pages on Facebook; Dogspotting (1.7
91 million members) and Dogspotting Society (974,000 members). Facebook users frequent these
92 types of pages to view and share photos or videos of dogs and information about dog ownership.
93 Two of the researchers also posted the link on their personal Facebook pages. It is known to the

94   researchers that the survey was posted elsewhere on Facebook by individuals other than the
95   researchers. The link remained live for 14 weeks during the summer of 2019.
96
97   Discrete data were compiled and analyzed using Microsoft Excel. Statistical significance was
98   determined using chi-squared testing with a p-value of less than 0.001 unless specifically noted.
99   When presenting percentages to compare cooked and raw feeding groups, summation of
100   percentages is always 100%. Qualitative analysis of the fill-in data was undertaken using the
101   RStudio text mining (tm) package and word cloud generator package (wordcloud) to discover
102   relevant word frequencies and visually represent the data. Qualitative data were mined to exclude
103   common English stop words and combine words with the same stem (e.g. risk and risky) as well
104   as words with an identical meaning (e.g. stool, feces, faeces, poop, poo).
105

Results

Demographics

108   Four hundred and nineteen people of variable age responded to the survey. Most respondents
109   were female (n=393, 93.6%), omnivorous (n=357, 85.6%), and did not work as part of the
110   animal industry or animal related field (n=306, 73.2%). Only a minority of respondents lived in
111   households with immunocompromised individuals (n=33, 7.9%), pregnant women (n=10, 2.4%)
112   or children under ten years of age (n=43, 10.3%). Our survey participants hailed from sixteen
113   countries on five continents, with the United States (n=206, 58.4%) and the United Kingdom
114   (n=97, 27.5%) as the most represented and second most represented countries, respectively.
115   (Table 1).
116

Establishment of Diet

118   When asked how owners established their dog's diet, 24.4% (n=101) of respondents said they
119   followed a recommendation from a veterinarian, veterinary nurse or veterinary technician.
120   Information published online from a non-veterinary source (n=54, 13.0%) and information
121   published by a veterinarian or veterinary nutritionist (n=50, 12.1%) were also popular choices.
122   The remainder of respondents (n=209, 50.5%) established their dog's diet in myriad other ways,
123   like recommendations from friends and family, tradition (what they have always fed),
124   recommendation of the breeder or rescue/shelter and recommendation from breed specific
125   literature, among others (101 discrete answers were offered).
126
127   Owners were asked what their dogs ate most of the time (their main diet). The majority of
128   respondents fed their dog a CCD as the main diet, in the forms of dry/kibble or
129   wet/canned/sachet (n=267, 63.7%). Commercially prepared raw food (n=54, 12.9%) was the
130   next most popular choice, followed by a homemade raw diet (n=52, 12.4%), a prescription diet
131   for a medical condition (n=30, 7.2%) and a homemade cooked diet (n=16, 3.8%). For the
132   purposes of this paper, owners who fed predominantly raw diets (as their main diet) in any form

133   will herein be referred to as "raw feeders" while owners who fed predominantly cooked diets in
134   any form will be referred to as "cooked feeders".

135

136   **Perceptions of Diets**
137   Respondents were asked to rate various diets on scales of 1 to 5 (where 1 is lowest and 5 is
138   highest) in terms of perceived nutritional value, as well as risks to both human and dog health;
139   the diets they rated were CCDs, commercially prepared RMBDs, and homemade RMBDs.

140

141   When asked about nutrition, raw feeders were more likely to rate RMBDs as highly nutritious (4
142   or 5 out of 5) than cooked feeders were (p<0.001 for all comparisons made), and made only a
143   small distinction between commercial or homemade RMBDs, with 83.5% (n=79) of raw feeders
144   rating commercial RMBDs as highly nutritious and 73.6% (n=78) rating homemade RMBDs as
145   highly nutritious. In contrast, cooked feeders made a greater distinction between commercial and
146   homemade diets than between cooked and raw; 52.7% (n=164) of cooked feeders rated CCDs as
147   highly nutritious and 51.6% (n=119) gave the same rating to commercial RMBDs. Only 35.7%
148   (n=106) of cooked feeders rated homemade RMBDs as highly nutritious, and only 12.5% (n=13)
149   of raw feeders rated CCDs as highly nutritious (Figure 1).

150

151   When asked about risk, all participants rated CCDs as low risk to humans; there was no
152   statistical difference between the groups (p=0.93). However, cooked feeders perceived RMBDs
153   as riskier to both their dog's health and human health than raw feeders did (p<0.001 for all).
154   Both groups viewed CCDs as riskier to dog health than to human health: while approximately
155   15.0% of both groups thought there was a high risk to human health (cooked feeders n=17, raw
156   feeders n=7), there was a significant difference in perception of risk to dog health between
157   groups. Forty-five cooked feeders (25.1%) rated CCDs as highly risky to dog health. The
158   results from raw feeders were more extreme: 65.3% (n=54) of them rated CCDs as highly risky
159   to dog health. (Figure 1).

160

161   **Perceptions of Nutritional Knowledge**
162   Two hundred and ninety-seven (70.9%) respondents had discussed nutrition with their
163   veterinarian. When asked to rank how knowledgeable they felt their veterinarian was about
164   nutrition where 1 was least knowledgeable and 5 was most knowledgeable, 59.9% (n=249) of
165   respondents gave their veterinarian a 4 or 5 out of 5. When asked to rank how knowledgeable
166   owners felt they were about their dog's nutrition, 61.9% (n=260) gave themselves 4 or 5 out of 5.
167   Further analysis of this data shows a significant difference in responses given by raw feeders and
168   cooked feeders. When asked to rank their own nutritional knowledge on a scale of 1 to 5, 65.2%
169   (n=174) of cooked feeders ranked themselves as 4 or 5 out of 5, while 86.0% (n=85) of raw
170   feeders gave themselves the same score (p<0.001). Only 45.5% (n=33) of raw feeders gave their
171   veterinarian a 4 or 5 on the scale, whereas 78.0% (n=215) of cooked feeders ranked their
172   veterinarian as 4 or 5 out of 5 (p<0.001) (Figure 1).

173
174 **Free Text Answers**
175 Owners provided a variety of opinions via free-text boxes when asked about perceived benefits
176 and risks of raw feeding as well as why they chose to feed a RMBD or why they chose not to
177 feed a RMBD to their dog. These perceptions are visually summarized in the word clouds
178 (Figures 2-5). The most repeated words for benefits of RMBDs were "health" (frequency (f)=
179 105), "better" (f=104), "coat" (f=59), and "teeth" (f=50) (Figure 2) and the most repeated words
180 for risks were "bacteria" (f=91), "nutrition" (f=72), "risk" (f=63), and "Salmonella" (f=39)
181 (Figure 3). When asked why they chose to feed raw, owners most often used the words "health"
182 (f=54), "better" (f=23), "nutrition" (f=20)" and "coat" (f=14) (Figure 4). Conversely, when asked
183 why they chose not to feed raw, the most common words were "expensive" (f=59), "time"
184 (f=45), "risk" (f=42), and "convenience" (f=36) (Figure 5).
185

186 ## Discussion
187 Our demographic data indicates that our survey respondents were overwhelmingly female
188 (n=393, 93.6%) and seems to be a typical result in surveys of pet owners.[5] Though we did have
189 responses from a breadth of countries, the United States and the United Kingdom were the two
190 most represented countries, which is an expected result given that our questionnaire was only
191 available in English.
192

193 Comparing raw feeders with cooked feeders revealed many key distinctions in opinion and
194 perception between the two groups. To start, raw feeders and cooked feeders differed in their
195 assessments of the nutritional quality of various diets. As we hypothesized, raw feeders
196 perceived homemade and commercial RMBDs both as highly nutritious, making little distinction
197 between the two preparations. This perception is not supported by scientific evidence; numerous
198 studies have demonstrated the risks of nutritional imbalances inherent in homemade diets.[6-9]
199 Even homemade diets formulated by veterinarians have been shown to sometimes be incomplete
200 though they tend to have fewer and less severe deficiencies than those formulated by non-
201 veterinarians.[6] Homemade diets should always be formulated in consultation with board-
202 certified veterinary nutritionists to ensure they are properly balanced. A wide array of medical
203 conditions can be caused by improper nutrient balance including nutritional secondary
204 hyperparathyroidism, developmental orthopedic conditions, and even canine nutritional
205 hyperthyroidism; there are multiple documented cases of dogs developing these conditions as a
206 result of eating improperly balanced homemade RMBDs.[10-13] These risks are concerning,
207 especially as a recent international study of pet owners found that 89% of raw-feeding dog
208 owners fed homemade raw diets.[14] A separate survey aimed specifically at raw feeders found
209 that only 15% of respondents formulated their dog's RMBD with guidance from a veterinarian or
210 nutritionist.[15] The fact that raw feeders are not making a distinction between the nutritional
211 quality of homemade and commercial RMBDs and that many seem to be formulating their dog's
212 diet without appropriate guidance suggests a need for further owner education on the risks of

213   feeding an improperly balanced homemade diet. By comparison, the majority of cooked feeders
214   did distinguish between their assessments of the two preparations, with few of them rating
215   homemade RMBDs as highly nutritious and a larger number rating both commercial RMBDs
216   and CCDs as highly nutritious. It is worth noting that a RMBD being commercially produced is
217   not a guarantee that it is nutritionally balanced, particularly given that legal standards for pet
218   food vary from country to country. The WSAVA recommends only feeding commercial pet food
219   (raw or cooked) from companies that meet specific standards, including the full-time
220   employment of a board-certified veterinary nutritionist.[16]
221
222   Unsurprisingly only one in eight raw feeders viewed CCDs as highly nutritious. Cooked feeders
223   demonstrated interesting perceptions of CCDs, with just over half of them (n=164, 52.7%) rating
224   CCDs as highly nutritious; that is an alarmingly low number considering this is the diet they
225   chose to feed to their dogs. When we combine these findings with the top reasons that owners
226   provided for not feeding RMBDs ("time", "expensive", "convenience"), we can postulate that
227   diet choice is multifactorial and that lifestyle factors may be playing a larger role than nutritional
228   value for some owners. This is an area that begs further research to understand exactly why
229   cooked feeders are choosing to feed a diet they do not view as particularly high in nutritional
230   value.
231
232   When it comes to risks associated with raw and cooked diets, raw feeders and cooked feeders
233   again had different perceptions. Cooked feeders were far more likely to rate both commercial
234   and homemade RMBDs as higher risk to both dog and human health than CCDs. This is
235   reassuring as it demonstrates an awareness of the published dangers surrounding the handling
236   and consumption of raw meat products. One of those risks is of zoonotic infection with
237   *Salmonella*, which is one of the most commonly found pathogens in RMBDs and may pose a
238   greater threat to owners than their pets; dogs have been found less likely to exhibit clinical signs
239   of *Salmonella* infections even while shedding the bacteria into their environments, and multiple
240   studies have demonstrated higher incidence of *Salmonella* shedding in dogs fed RMBDs.[17-20]
241   This risk is not necessarily mitigated by strict hygiene standards; *Salmonella* species have been
242   shown to persist in dog bowls used for RMBDs, even after being cleaned in a dishwasher at
243   85°C or scrubbed and soaked in bleach.[21] Salmonella is the most common pathogenic risk from
244   raw feeding cited by our respondents, though it is by no means the only risk associated with
245   RMBDs; other examples of pathogens found in studies of RMBDs include the bacteria
246   *Escherichia coli* species, *Campylobacter* species, *Clostridium perfringens,* and *Brucella suis,* as
247   well as the parasites *Toxoplasma gondii*, *Sarcoystis cruzi,* and *Sarcoystis tenella.* These
248   contaminants lead to a range of disorders, including polyradiculoneuritis in the case of
249   *Campylobacter spp.* infection.[22-25] There have also been concerning reports of antimicrobial-
250   resistant pathogens found in commercial RMBDs, from strains of *E. coli* to various *Salmonella*
251   serovars, and there are ongoing reports of cats in the UK contracting Tuberculosis from a
252   particular brand of commercial RMBD.[26-28] Many of these risks have been further explored by

253 Davies et al in their 2019 review.[2] One recent study found that only 63 out of 16,475 raw-feeding
254 households self-reported that a member of their household became ill due to raw products fed to
255 their pet(s), and of those households, only 39 had the pathogen confirmed by a laboratory.[29] This
256 seems to indicate a very minimal human risk from feeding RMBDs to pets, however the two
257 most commonly reported pathogens in that study, *Campylobacter* and *Salmonella* are both
258 considered to be widely underdiagnosed and underreported.[30, 31] It is difficult to gauge the exact
259 degree to which zoonotic transmission of pathogens occurs from the feeding of RMBDs but the
260 risk is certainly present. While responses from cooked feeders imply some level of understanding
261 of the pathogenic risks of RMBDs, they also demonstrate a perception that commercial RMBDs
262 are less risky than homemade RMBDs when there is little evidence to support this. By contrast,
263 raw feeders were not likely to rate any type of RMBD as highly risky to either human or animal
264 health. This correlates with Morelli et al who found that 65% of raw feeders believed that
265 RMBD consumption cannot make dogs ill.[15] These findings clearly indicate a need for further
266 owner education on the pathogenic risks of RMDBs.
267
268 Interestingly, a quarter of cooked feeders (n=45, 25.1%) and roughly two-thirds of raw feeders
269 (n=13, 65.3%) rated CCDs as highly risky when it comes to canine health. It is worth noting that
270 participants were not given an opportunity to explain the reasoning behind their ratings, so it is
271 unclear what perceived risks were being associated with CCDs. Cooked pet food can be host to
272 microbial pathogens, however, the risk is significantly lower than for RMBDs; a study of over
273 1,000 commercially available pet foods found evidence of *Salmonella* or *Listeria* species in
274 40.8% of raw samples and only 0.42% of cooked ones.[32] However there have been some highly
275 publicized incidents of dry food recalls including a problem in 2007 with melamine
276 contamination and more recently excess levels of vitamin D which may have been a factor for
277 owners in answering this question.[33, 34] Exploring owner-perceived risks associated with
278 commercially cooked food would be an interesting area for further research.
279
280 When respondents were asked to rate their veterinarian's knowledge of nutrition, 59.9% (n=249)
281 of owners surveyed believed their veterinarian to be highly knowledgeable (4 or 5 out of 5). A
282 prior survey by Morgan et al found that only 35.9% of surveyed dog owners trusted their
283 veterinarians as a knowledge resource with respect to pet nutrition.[5] While that statistic makes
284 our figure seem surprisingly high, further analysis of our data shows a large difference in the
285 assessment of veterinarian nutritional knowledge depending on the diet fed by the owner in
286 question; cooked feeders gave their veterinarian an average score of 3.9 out of 5 while raw
287 feeders gave an average score of only 2.9 out of 5. The stark difference between the perceptions
288 of the two groups demonstrates a need for better communication between veterinarians and their
289 raw feeding clients, with specific regard to veterinarians' ability to inspire confidence in their
290 own nutritional knowledge. Furthermore, this emphasizes the need for a strong foundation in
291 nutrition in veterinary education alongside the communication skills and confidence to raise
292 questions and start evidence-based discussions about nutrition in the consulting room.

293

294   One of the novel aspects of this research was allowing owners to provide their opinions on raw
295   feeding in their own words using free-text boxes. When all owners were asked about the benefits
296   of raw feeding, specific keywords repeatedly arose such as "teeth", "coat", "natural", "digestion"
297   and "allergen", along with general positive words like "better" and "health". Highlighting the
298   areas where owners think raw feeding benefits their dogs can serve as a starting point for
299   veterinarians to open discussion about nutrition and help them to understand what owners find
300   appealing about the practice of feeding RMBDs.

301

302   When asked why raw feeders chose to feed RMBDs, frequently repeated words were more often
303   vague: "health", "better", "issues" and "benefits". These did not further the understanding of the
304   motivation behind raw feeding and may expose an inability of raw feeders to agree on reasons to
305   choose RMBDs. The lack of specific terms also emphasizes the dearth of peer-reviewed
306   published data on the benefits of raw feeding.

307

308   Asking owners about the risks associated with raw feeding generated less ambiguous results,
309   with words like "bacteria", "Salmonella", "contamination", "bone" and "unbalanced" being
310   frequently repeated. This suggests that at least a subset of the population is informed about some
311   of the documented risks of RMBDs. When owners who did not feed RMBDs were asked why
312   they avoid the practice, they used tangible words again, with "time", "expensive", "risk", and
313   "convenience" being some of the most repeated words. It is worth pointing out that the most
314   common answers for why owners chose not to feed RMBDs do not directly correlate with the
315   risks they listed previously. This perhaps indicates that it is not the risks associated with RMBDs
316   that is preventing these owners from choosing that diet for their dog.

317

318   Compiling the free-text data into word clouds or tag clouds provides an intuitive and accessible
319   way to visualize the data, rather than simply relying on frequency graphs. It demonstrates the
320   complexity and diversity of data while highlighting the most important and frequently used
321   keywords as the largest and centrally located words.[35] The use of word clouds originated in the
322   world wide web as a way to compile tags but has since evolved as a useful tool for text
323   analytics.[36] Their use in scientific literature has not been widespread, thus this application
324   represents an innovative way to present our data. Our word clouds summarize a massive amount
325   of free-text data and allow us to pick out trends and keywords quickly and efficiently while
326   providing an aesthetically pleasing medium that is easy for a layperson to interpret.

327

328   The free-text boxes were a particular strength of this survey as it allowed owners a chance to
329   express their perceptions in their own words. Additional strengths included our wide geographic
330   spread of participants and variety in professional background of participants. Limitations of the
331   survey include aspects that potentially restricted participation, in particular the need for
332   respondents to be proficient in the English language as well as have internet and social media

333 access. The varying geographical and cultural backgrounds of respondents may also have led to
334 some confusion in terminology, for example, the term 'traditional' was used multiple times in the
335 survey and yet will imply different connotations to a respondent depending on their background.
336 As with many studies, sample size and participant engagement could have been more robust and
337 will be a point of attention for future research.
338

Conclusions

340 This study used a novel questionnaire to assess dog owner perceptions around canine feeding of
341 raw meat-based and commercial cooked diets. Dog owners have immense choice when deciding
342 on a diet for their pets and the data indicated that an increasing number of them are choosing
343 RMBDs, despite concerns cited by leading veterinary bodies.[2] This contradiction indicates a
344 clear need to understand what specifically is driving owners to choose RMBDs or CCDs, though
345 it is equally important to assess what causes owners to avoid feeding these diet types too.
346

347 We found our hypotheses to be largely correct; dog owners who choose to feed RMBDs
348 generally viewed the practice to be less risky to both human and dog health than owners who did
349 not feed RMBDs. Raw feeders also rated raw diets as significantly more nutritious than CCDs.
350 Moreover, over six in seven raw feeders perceived themselves as highly knowledgeable about
351 nutrition, while only half viewed their veterinarian as knowledgeable. Conversely, cooked
352 feeders perceived their veterinarians as more knowledgeable than they were about their dog's
353 nutrition, but only half of them viewed CCDs as a nutritious diet. Further potential areas of
354 research could include probing into specific claims made by raw feeders in the free-text portion
355 of the questionnaire as well as exploring why cooked feeders choose their diet.
356

Figure 1

Owner responses to rating questions

Dog owner responses when asked to rate cooked diets or raw diets on three variables (nutritional value, risk to dog health, or risk to human health) as well as their own knowledge of nutrition and their veterinarian's knowledge of nutrition on a 5-point scale, where 1 was the least and 5 was the most of each variable, separated by owner's chosen diet (cooked feeders versus raw feeders).

Figure 2

Perceived benefits of raw diets

Response to the prompt: What benefits are you aware of associated with feeding a raw diet?

Figure 3

Perceived risks of raw diets

Response to the prompt: What risks are you aware of associated with feeding a raw diet?

Figure 4

Reasons for feeding a raw diet.

Response to the prompt: If you feed your dog a raw diet, why?

Figure 5

Reasons for not feeding a raw diet.

Response to the prompt: If you do not feed your dog a raw diet, why not?

Demographics.

Demographic data for survey respondents.

Variable	Number of respondents	%
