The daily average natural rainfall amounts in the five regions of Thailand can be estimated using the confidence intervals for the common mean of several delta-lognormal distributions based on the fiducial generalized confidence interval (FGCI), large sample (LS), method of variance estimates recovery (MOVER), parametric bootstrap (PB), and highest posterior density intervals based on Jeffreys' rule (HPD-JR) and normal-gamma-beta (HPD-NGB) priors. Monte Carlo simulation was conducted to assess the performance in terms of the coverage probability and average length of the proposed methods. The numerical results indicate that MOVER and PB provided better performances than the other methods in a variety of situations, even when the sample case was large. The efficacies of the proposed methods were illustrated by applying them to real rainfall datasets from the five regions of Thailand.

12 ABSTRACT

13 The daily average natural rainfall amounts in the five regions of Thailand can be estimated using the
14 confidence intervals for the common mean of several delta-lognormal distributions based on the fiducial
15 generalized confidence interval (FGCI), large sample (LS), method of variance estimates recovery
16 (MOVER), parametric bootstrap (PB), and highest posterior density intervals based on Jeffreys' rule
17 (HPD-JR) and normal-gamma-beta (HPD-NGB) priors. Monte Carlo simulation was conducted to assess
18 the performance in terms of the coverage probability and average length of the proposed methods. The
19 numerical results indicate that MOVER and PB provided better performances than the other methods in
20 a variety of situations, even when the sample case was large. The efficacies of the proposed methods
21 were illustrated by applying them to real rainfall datasets from the five regions of Thailand.

22 INTRODUCTION

23 Approximately 82.2% of Thailand's cultivated land area depends on natural rainfall (Supasod, 2006),
24 thereby indicating its importance for Thai agriculture. However, it is a natural phenomenon with a
25 significant level of uncertainty that can cause natural disasters such as droughts, floods, and landslides.
26 In many countries around the world, extreme rainfall events have been increasing in frequency and
27 duration. On December 5, 2017, Storm Desmond led to heavy rainfall causing flooding in northern
28 England, Southern Scotland, and Ireland (Otto and Oldenborgh, 2017). On July 6–7, 2018, extreme
29 rainfall events such as floods and landslides affected over 5,000 houses, and approximately 1.9 million
30 people in Japan were evacuated from the at-risk area (Oldenborgh, 2018). In mid-September 2019, the
31 amount of rainfall was extreme during Tropical Storm Imelda in Southeast Texas, USA, where over
32 1,000 people were affected by large-scale flooding and there were 5 deaths (Oldenborgh et al., 2019).
33 Thus, it is necessary to assess how rainfall varies in each region of a country on a daily basis. Due to
34 the climate pattern and meteorological conditions, Thailand is commonly separated into five regions:
35 northern, northeastern, central, eastern, and southern. The rainfall in each region varies widely due to both
36 location and seasonality. Importantly, Thailand's rainfall data include many zeros with probability $\delta > 0$
37 and positive right-skewed data following a lognormal distribution for the remainder of the probability.
38 Thus, applying a delta-lognormal distribution (Aitchison, 1955) is appropriate.

39 The mean is a measure of the center of a set of observations (Casella and Berger, 2002) that can be
40 used in statistical inference, while functions of the mean such as the ratio or difference between two
41 means can also be used. These parameters have been applied in many research areas, such as medicine,
42 fish stocks, pharmaceuticals, and climatology. For example, they have been used for hypothesis testing of
43 the effect of race on the average medical costs between African American and Caucasian patients with
44 type I diabetes (Zhou et al., 1997), to estimate the mean charges for diagnostic tests on patients with

45 unstable chronic medical conditions (Zhou and Tu, 2000; Tian, 2005; Tian and Wu, 2007; Li et al., 2013),
 46 to estimate the maximum alcohol concentration in men in an alcohol interaction study (Tian and Wu,
 47 2007; Krishnamoorthy and Oral, 2015), to estimate the mean red cod density around New Zealand as
 48 an indication of fish abundance (Fletcher, 2008; Wu and Hsieh, 2014), and to estimate the mean of the
 49 monthly rainfall totals to compare rainfall in Bloemfontein and Kimberley in South African (Harvey and
 50 van der Merwe, 2012).

51 In practice, the mean has been widely used in many fields, as mentioned before. When independent
 52 samples are recorded from several situations, then the common mean is of interest when studying more
 53 than one population. Many researchers have investigated methods for constructing confidence interval
 54 (CIs) for the common mean of several distributions. For example, Fairweather (1972) proposed a linear
 55 combination of Student's t to construct CIs for the common mean of several normal distributions. Jordan
 56 and Krishnamoorthy (1996) solved the problem of CIs for the common mean under unknown and
 57 unequal variances based on Student's t and independent F variables from several normal populations.
 58 Krishnamoorthy and Mathew (2003) presented the generalized CI (GCI) and compared it with the CIs
 59 constructed by Fairweather (1972), and Jordan and Krishnamoorthy (1996). Later, Lin and Lee (2005)
 60 developed a GCI for the common mean of several normal populations. Tian and Wu (2007) provided CIs
 61 for the common mean of several lognormal populations using the generalized variable approach, which
 62 was shown to be consistently better than the large sample (LS) approach. Lin and Wang (2013) studied
 63 the modification of the quadratic method to make inference via hypothesis testing and interval estimation
 64 for several lognormal means. Krishnamoorthy and Oral (2015) proposed the method of variance estimates
 65 recovery (MOVER) approach for the common mean of lognormal distributions.

66 As mentioned earlier, many researchers have developed CIs for the common mean of several normal
 67 and lognormal distributions. However, there has not yet been an investigation of statistical inference
 68 using the common mean of several delta-lognormal distributions. Since the common mean is used to
 69 study more than one population, the average precipitation in the five regions in Thailand can be estimated
 70 using it as there is an important need to estimate the daily rainfall trends in these regions. Furthermore,
 71 the daily rainfall records from the five regions in Thailand satisfy the assumptions for a delta-lognormal
 72 distribution. Herein, CIs for the common mean of several delta-lognormal models based on the fiducial
 73 GCI (FGCI), LS, MOVER, parametric bootstrap (PB), and highest posterior density (HPD) intervals
 74 based on Jeffreys' rule (HPD-JR) and normal-gamma-beta (HPD-NGB) priors are proposed. The outline
 75 of this article is as follows. The ideas behind the proposed methods are detailed in Section 2. Numerical
 76 computations are reported in Section 3. In Section 4, the daily natural rainfall records of the five regions
 77 in Thailand are used to illustrate the efficacy of the methods. Finally, the paper is ended with a discussion
 78 and conclusions.

79 METHODS

80 Let $W_{ij} = (W_{i1}, W_{i2}, \dots, W_{in_i})$ be random samples drawn from a delta-lognormal distribution, for $i = 1, 2, \dots, k$
 81 and $j = 1, 2, \dots, n_i$. There are three parameters in this distribution: the mean μ_i , variance σ_i^2 and the
 82 probability of obtaining a zero observation δ_i . The distribution of W_{ij} is given by

$$H(w_{ij}; \mu_i, \sigma_i^2, \delta_i) = \begin{cases} \delta_i & ; w_{ij} = 0 \\ \delta_i + (1 - \delta_i)G(w_{ij}; \mu_i, \sigma_i^2) & ; w_{ij} > 0 \end{cases} \quad (1)$$

where $G(w_{ij}; \mu_i, \sigma_i^2)$ is a lognormal distribution function, denoted as $LN(\mu_i, \sigma_i^2)$ such that $\ln W_{ij} \sim$
 $N(\mu_i, \sigma_i^2)$. The number of zeros has a binomial distribution $n_{i(0)} = \#\{j : w_{ij} = 0\} \sim B(n_i, \delta_i)$. The popula-
 tion mean of W_{ij} is given by

$$\vartheta_i = (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) \quad (2)$$

83 The unbiased estimates of μ_i , σ_i^2 , and δ_i are $\hat{\mu}_i = n_{i(1)}^{-1} \sum_{j:w_{ij}>0} \ln W_{ij}$, $\hat{\sigma}_i^2 = (n_{i(1)} - 1)^{-1} \sum_{j:w_{ij}>0} [\ln W_{ij} - \hat{\mu}_i]^2$,
 84 and $\hat{\delta}_i = n_{i(0)}/n_i$, respectively, where $n_i = n_{i(0)} + n_{i(1)}$; $n_{i(1)} = \#\{j : w_{ij} > 0\}$. Suppose that the delta-
 85 lognormal mean in (2) for all k populations are the same, then according to Tian and Wu (2007) and
 86 Krishnamoorthy and Oral (2015), the common delta-lognormal mean is defined as

$$\vartheta = (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) \quad (3)$$

87 For the i^{th} sample, the estimates of ϑ_i are $\hat{\vartheta}_i^* = (1 - \hat{\delta}_i) \exp\left(\hat{\mu}_i + \frac{\hat{\sigma}_i^2}{2}\right)$ which contains the unbiased estimates
88 $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}_i$. According to Longford (2009), the expected value of $\hat{\vartheta}_i^*$ is derived as

$$E[\hat{\vartheta}_i^*] = [1 - E(\hat{\delta}_i)] E\left[\exp\left\{\hat{\mu}_i + \frac{\hat{\sigma}_i^2}{2}\right\}\right] \quad (4)$$

$$= (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) \left(\frac{l_i}{l_i - \sigma_i^2}\right)^{l_i/2} \quad (5)$$

89 where $\hat{\delta}_i \sim N\left(\delta_i, \frac{\delta_i(1-\delta_i)}{n_i}\right)$ as $n_i \rightarrow \infty$, $E[\exp(\hat{\mu}_i)] = \exp\left(\mu_i + \frac{\sigma_i^2}{2n_{i(1)}}\right)$ and $E[\exp(c_i Y_i)] = (1 - 2c_i)^{-l/2}$;
90 $Y_i = l_i \frac{\hat{\sigma}_i^2}{\sigma_i^2} \sim \chi_{l_i}^2$ and $c_i = \frac{\sigma_i^2}{2l_i}$, $\hat{\sigma}_i^2 = (n_{i(1)} - 1)^{-1} \sum_{j=1}^{n_{i(1)}} [\ln(W_{ij}) - \hat{\mu}_i]^2$. If $\frac{l_i - \sigma_i^2}{l_i} = \exp\left[\frac{-2\sigma_i^2}{l_i} \left(\frac{1}{2} - \frac{1}{2n_{i(1)}}\right)\right]$, then
91 we can obtain that

$$E[\hat{\vartheta}_i^*] = (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2n_{i(1)}}\right) \left\{ \exp\left[\frac{-2\sigma_i^2}{l_i} \left(\frac{1}{2} - \frac{1}{2n_{i(1)}}\right)\right] \right\}^{-l_i/2}$$

$$= (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) \quad (6)$$

92 According to Aitchison and Brown (1963), the Aitchison estimate of ϑ_i is expressed as

$$\hat{\vartheta}_i^{(Ait)} = \begin{cases} 0 & ; n_{i(1)} = 0 \\ w_{i1}/n_i & ; n_{i(1)} = 1 \\ (1 - \hat{\delta}_i) \exp(\hat{\mu}_i) \psi_{n_{i(1)}}\left(\frac{\hat{\sigma}_i^2}{2}\right) & ; n_{i(1)} > 1 \end{cases} \quad (7)$$

93 where $\psi_a(b)$ is a Bessel function defined as

$$\psi_a(b) = 1 + \frac{(a-1)b}{a} + \frac{(a-1)^3}{a^2 2!} \frac{b^2}{a+1} + \frac{(a-1)^5}{a^3 3!} \frac{b^3}{(a+1)(a+3)} + \dots \quad (8)$$

94 To investigate the unbiased estimate $\hat{\vartheta}_i^{(Ait)}$, the expected value is

$$E\left[\hat{\vartheta}_i^{(Ait)}\right] = \sum_{j=1}^{n_i} P(n_{i(1)} = j) E[\hat{\vartheta}_i | n_{i(1)} = j]$$

$$= 0 + P(n_{i(1)} = 1) E[w_{i1}/n_i] + \sum_{j=2}^{n_i} P(n_{i(1)} = j) E[\hat{\vartheta}_i | n_{i(1)} = j]$$

$$= P(n_{i(1)} = 1) \frac{\exp\left(\mu_i + \frac{\sigma_i^2}{2}\right)}{n_i} + \sum_{j=2}^{n_i} P(n_{i(1)} = j) E\left[\frac{n_{i(1)}}{n_i} \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) | n_{i(1)} = j\right]$$

$$= \sum_{j=0}^{n_i} P(n_{i(1)} = j) E\left[\frac{n_{i(1)}}{n_i} \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) | n_{i(1)} = j\right]$$

$$= E\left[\frac{n_{i(1)}}{n_i} \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right)\right]$$

$$= (1 - \delta_i) \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right)$$

According to Shimizu and Iwase (1981), the uniformly minimum variance unbiased (UMVU) estimate of ϑ_i is

$$\hat{\vartheta}_i^{(Shi)} = \begin{cases} 0 & ; n_{i(1)} < 1 \\ \frac{n_{i(1)}}{n_i} \exp(\hat{\mu}_i) {}_0F_1 \left(\frac{n_{i(1)}-1}{2}; \frac{n_{i(1)}-1}{4n_{i(1)}} S_i^2 \right) & ; n_{i(1)} \geq 1 \end{cases} \quad (9)$$

where $S_i^2 = \sum_{j=1}^{n_{i(1)}} [\ln(W_{ij}) - \hat{\mu}_i]^2$ and ${}_0F_1(a; z) = \sum_{m=0}^{\infty} \frac{z^m}{(a)_m m!}$;

$$(a)_m = \begin{cases} 1 & ; m = 0 \\ a(a+1)\dots(a+m-1) & ; m \geq 1 \end{cases} \quad (10)$$

95 From Kunio (1983), $E \left[{}_0F_1 \left(\frac{n_{i(1)}-1}{2}; \frac{a}{2} S_i^2 \right) \right] = \exp(a\sigma^2)$ is obtained, then

$$\begin{aligned} E \left[\hat{\vartheta}_i^{(Shi)} \right] &= E \left[\frac{n_{i(1)}}{n} \exp(\hat{\mu}_i) {}_0F_1 \left(\frac{n_{i(1)}-1}{2}, \frac{n_{i(1)}-1}{4n_{i(1)}} S_i^2 \right) \right] \\ &= \frac{n_i(1-\delta_i)}{n_i} \exp \left[\mu_i + \frac{\sigma_i^2}{2n_{i(1)}} \right] \exp \left[\frac{n_{i(1)}-1}{2n_{i(1)}} \sigma_i^2 \right] \\ &= (1-\delta_i) \exp \left(\mu_i + \frac{\sigma_i^2}{2} \right) \end{aligned} \quad (11)$$

96 where $E(n_{i(1)}) = n_i(1-\delta_i)$. The asymptotic variance of $\hat{\vartheta}_i^{(Shi)}$ is given by

$$\begin{aligned} \text{Var} \left[\hat{\vartheta}_i^{(Shi)} \right] &= \exp(2\mu_i + \sigma_i^2) \left[\frac{1}{n_i^2} \sum_{j=1}^{n_i} \binom{n_i}{j} (1-\delta_i)^j \delta^{n_i-j} j^2 \exp \left(\frac{\sigma_i^2}{j} \right) \right. \\ &\quad \left. {}_0F_1 \left(\frac{j-1}{2}; \frac{(j-1)^2}{4j^2} \sigma_i^4 \right) - (1-\delta_i)^2 \right] \\ &= \frac{\exp(2\mu_i + \sigma_i^2)}{n_i} \left[\delta_i(1-\delta_i) + \frac{1}{2}(1-\delta_i)(2\sigma_i^2 + \sigma_i^4) \right] + O(n^{-2}) \end{aligned} \quad (12)$$

97 Actually, $\psi_{n_{i(1)}} \left(\frac{\hat{\sigma}_i^2}{2} \right) = {}_0F_1 \left(\frac{n_{i(1)}-1}{2}; \frac{n_{i(1)}-1}{4n_{i(1)}} S_i^2 \right)$ such that $\hat{\vartheta}_i^{(Shi)}$ and $\hat{\vartheta}_i^{(Ait)}$ are the unbiased estimates of ϑ_i
98 under different ideas, although their variances are the same i.e. $\text{Var} \left[\hat{\vartheta}_i^{(Shi)} \right] = \text{Var} \left[\hat{\vartheta}_i^{(Ait)} \right]$. Using $\hat{\mu}_i$, $\hat{\sigma}_i^2$,
99 and $\hat{\delta}_i$ from the samples, the estimated delta-lognormal mean $\hat{\vartheta}_i^{(Ait)}$ and variance of $\hat{\vartheta}_i^{(Ait)}$ are obtained.
100 The following methods are the detailed construction of the CIs for the common delta-lognormal mean.

101 Fiducial Generalized Confidence Interval

102 Fiducial inference was introduced by Fisher (1930). Fisher's fiducial argument was used to develop a
103 generalized fiducial recipe that could be extended to the application of fiducial ideas (Hannig, 2009). The
104 concept of the fiducial interval has been advanced by the idea of the generalized pivotal quantity (GPQ)
105 such that it is directly used to apply for generalized inference. Later, Hannig et al. (2006) argued that a
106 subclass of GPQs, the fiducial GPQ (FGPQ), provides a framework that shows the connection between
107 a distribution and a parameter. Recall that $\hat{\mu}_i \sim N(\mu_i, \sigma_i^2/n_{i(1)})$ and $(n_{i(1)}-1)\hat{\sigma}_i^2/\sigma_i^2 \sim \chi_{n_{i(1)}-1}^2$ are the
108 independent random variables. The structure functions of $\hat{\mu}_i$ and $\hat{\sigma}_i^2$ are

$$\hat{\mu}_i = \mu_i + V_i \sqrt{\frac{\sigma_i^2}{n_{i(1)}}} \quad \text{and} \quad \hat{\sigma}_i^2 = \frac{\sigma_i^2 U_i}{n_{i(1)}-1} \quad (13)$$

109 which are the function of V_i and U_i , respectively, where $V_i \sim N(0,1)$ and $U_i \sim \chi_{n_{i(1)}-1}^2$. Given the
110 observed values, the estimates $\hat{\mu}_i$ and $\hat{\sigma}_i^2$ can be obtained, and the unique solution of $(\hat{\mu}_i, \hat{\sigma}_i^2) =$
111 $\left(\mu_i + V_i \sqrt{\frac{\sigma_i^2}{n_{i(1)}}}, \frac{\sigma_i^2 U_i}{n_{i(1)}-1} \right)$ becomes

$$\mu_i = \hat{\mu}_i - V_i \frac{\hat{\sigma}_i}{\sqrt{n_{i(1)}}} \sqrt{\frac{n_{i(1)} - 1}{U_i}}, \quad \sigma_i^2 = \frac{(n_{i(1)} - 1) \hat{\sigma}_i^2}{U_i} \quad (14)$$

112 The respective FGPQs of μ_i and σ_i^2 are

$$G_{\mu_i} = \hat{\mu}_i - V_i^* \frac{\hat{\sigma}_i}{\sqrt{n_{i(1)}}} \sqrt{\frac{n_{i(1)} - 1}{U_i^*}} \quad (15)$$

$$G_{\sigma_i^2} = \frac{(n_{i(1)} - 1) \hat{\sigma}_i^2}{U_i^*} \quad (16)$$

113 where V_i^* and U_i^* are independent copies of V_i and U_i , respectively. Hasan and Krishnamoorthy (2018)
 114 developed the FGPQ of δ_i using a beta distribution as $G_{\delta_i} \sim \text{Beta}(\alpha_i, \beta_i)$; $\alpha_i = n_{i(1)} + 0.5$ and $\beta_i = n_{i(0)} + 0.5$.
 115 The FGPQ of ϑ based on k individual samples is

$$G_{\vartheta} = \frac{\sum_{i=1}^k G_{w_i} G_{\vartheta_i}}{\sum_{i=1}^k G_{w_i}} \quad (17)$$

116 where $G_{\vartheta_i} = G_{\delta_i} \exp(G_{\mu_i} + G_{\sigma_i^2}/2)$, $G_{w_i} = 1/G_{\text{Var}[\hat{\vartheta}_i^{(Ait)}]}$, and
 117 $G_{\text{Var}[\hat{\vartheta}_i^{(Ait)}]} = \exp(2G_{\mu_i} + G_{\sigma_i^2}) [G_{\delta_i}(1 - G_{\delta_i}) + \frac{1}{2}G_{\delta_i}(2G_{\sigma_i^2} + G_{\sigma_i^4})]/n_i$. Thus, the $100(1 - \zeta)\%$ FGCI for
 118 ϑ is

$$CI_{\vartheta}^{(fgci)} = [L_{\vartheta}^{(fgci)}, U_{\vartheta}^{(fgci)}] = [G_{\vartheta}(\zeta/2), G_{\vartheta}(1 - \zeta/2)] \quad (18)$$

119 where $G_{\vartheta}(\zeta)$ denotes the ζ^{th} percentiles of G_{ϑ} . Algorithm 1 shows the computational steps for obtaining
 120 the FGCI.

121 **Algorithm 1: FGCI**

- 122 1) Generate $V_i \sim N(0, 1)$ and $U_i \sim \chi_{n_{i(1)}-1}^2$ are independent.
- 123 2) Compute the FGPQs G_{μ_i} , $G_{\sigma_i^2}$ and G_{δ_i} .
- 124 3) Compute G_{w_i} and G_{ϑ_i} leading to obtain G_{ϑ} .
- 125 4) Repeat steps 1-3, a number of times, $m=2500$, compute 95%FGCI for ϑ , as given in (18).

126 **Large Sample Interval**

127 Recall that the Aitchison estimator is $\hat{\vartheta}_i^{(Ait)} = (1 - \hat{\delta}_i) \exp(\hat{\mu}_i) \psi_{n_{i(1)}}(\hat{\sigma}_i^2/2)$ and the variance of $\hat{\vartheta}_i^{(Ait)}$
 128 is $\text{Var}[\hat{\vartheta}_i^{(Ait)}] = \exp(2\mu_i + \sigma_i^2) [\delta_i(1 - \delta_i) + \frac{1}{2}(1 - \delta_i)(2\sigma_i^2 + \sigma_i^4)]/n_i$. The approximated variance is ob-
 129 tained by replacing $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}_i$. The pooled estimate of ϑ_i is given by

$$\hat{\vartheta} = \frac{\sum_{i=1}^k w_i \hat{\vartheta}_i^{(Ait)}}{\sum_{i=1}^k w_i} \quad (19)$$

130 where $w_i = 1/\widehat{\text{Var}}[\hat{\vartheta}_i^{(Ait)}]$. Hence, the $100(1 - \zeta)\%$ LS interval for ϑ is obtained as

$$CI_{\vartheta}^{(ls)} = [L_{\vartheta}^{(ls)}, U_{\vartheta}^{(ls)}] = \left[\hat{\vartheta} - z_{1-\frac{\zeta}{2}} \sqrt{1/\sum_{i=1}^k w_i}, \hat{\vartheta} + z_{1-\frac{\zeta}{2}} \sqrt{1/\sum_{i=1}^k w_i} \right] \quad (20)$$

131 where z_{ζ} denotes the ζ^{th} percentiles of standard normal $N(0, 1)$. The LS interval can be estimated easily
 132 via Algorithm 2.

133 **Algorithm 2: LS**

- 134 1) Compute $\hat{\vartheta}_i^{(Ait)}$ and $\widehat{Var}[\hat{\vartheta}_i^{(Ait)}]$.
 135 2) Compute $\hat{\vartheta}$.
 136 3) Compute 95%LS interval for ϑ , as given in (20).

137 **Method of Variance Estimates Recovery**

138 This method produces a closed-form CI that is easy to compute. For this reason, the MOVER CI for
 139 the common delta-lognormal mean is considered for k individual random samples. The MOVER for a
 140 linear combination of $\vartheta_i; i = 1, 2, \dots, k$ is as follows. Let $\hat{\vartheta}_1, \hat{\vartheta}_2, \dots, \hat{\vartheta}_k$ be independent unbiased estimators
 141 of $\vartheta_1, \vartheta_2, \dots, \vartheta_k$, respectively. In addition, let $[l_i, u_i]$ stand for the $100(1 - \zeta)\%$ CI for ϑ_i . According to
 142 Krishnamoorthy and Oral (2015), the $100(1 - \zeta)\%$ MOVER for $\sum_{i=1}^k c_i \vartheta_i$ is given by

$$CI_{\sum_{i=1}^k c_i \vartheta_i} = [L_{\sum_{i=1}^k c_i \vartheta_i}, U_{\sum_{i=1}^k c_i \vartheta_i}]$$

$$= \left[\sum_{i=1}^k c_i \hat{\vartheta}_i - \sqrt{\sum_{i=1}^k c_i^2 (\hat{\vartheta}_i - l_i^*)^2}, \sum_{i=1}^k c_i \hat{\vartheta}_i + \sqrt{\sum_{i=1}^k c_i^2 (\hat{\vartheta}_i - u_i^*)^2} \right] \quad (21)$$

143 where $l_i^* = \begin{cases} l_i & ; c_i > 0 \\ u_i & ; c_i < 0 \end{cases}$ and $u_i^* = \begin{cases} u_i & ; c_i > 0 \\ l_i & ; c_i < 0 \end{cases}$. Next, the closed-form CIs for ϑ_i are needed to construct
 144 MOVER for ϑ . Thus, ϑ_i is log-transformed as

$$\ln \vartheta_i = \ln \delta_i^* + (\mu_i + \sigma_i^2) \quad (22)$$

145 where $\delta_i^* = 1 - \delta_i$. Let $\hat{\mu}_i$, and $\hat{\sigma}_i^2$ and $\hat{\delta}^*$ be the unbiased estimates of μ_i , σ_i^2 , and δ_i , respectively. The
 146 MOVER for a single delta-lognormal mean presented by Hasan and Krishnamoorthy (2018), the MOVER
 147 for ϑ_i is given by

$$L_{\vartheta_i} = \exp \left\{ \ln \hat{\delta}_i^* + (\hat{\mu}_i + \hat{\sigma}_i^2) - \sqrt{(\ln \hat{\delta}_i^* - l_{\ln \delta_i^*})^2 + (\hat{\mu}_i + \hat{\sigma}_i^2 - l_{\mu_i + \sigma_i^2})^2} \right\}$$

$$U_{\vartheta_i} = \exp \left\{ \ln \hat{\delta}_i^* + (\hat{\mu}_i + \hat{\sigma}_i^2) - \sqrt{(\ln \hat{\delta}_i^* - u_{\ln \delta_i^*})^2 + (\hat{\mu}_i + \hat{\sigma}_i^2 - u_{\mu_i + \sigma_i^2})^2} \right\} \quad (23)$$

148 where

$$(l_{\ln \delta_i^*}, u_{\ln \delta_i^*}) = \ln \left[\left(\hat{\delta}_i^* + \frac{T_{i,\zeta/2}^2}{2n_i} \mp T_{i,1-\zeta/2} \sqrt{\frac{\hat{\delta}_i^* (1 - \hat{\delta}_i^*)}{n_i} + \frac{T_{i,\zeta/2}^2}{4n_i^2}} \right) / (1 + T_{i,\zeta/2}^2/n_i) \right]$$

$$(l_{\mu_i + \sigma_i^2}, u_{\mu_i + \sigma_i^2}) = \left[(\hat{\mu}_i + \hat{\sigma}_i^2/2) - \left\{ \left(\frac{Z_{i,\zeta/2} \hat{\sigma}_i^2}{n_{i(1)}} \right)^2 + \frac{\hat{\sigma}_i^4}{4} \left(1 - \frac{n_{i(1)} - 1}{\chi_{i,1-\zeta/2, n_{i(1)} - 1}^2} \right)^2 \right\}^{1/2}, \right. \quad (24)$$

$$\left. (\hat{\mu}_i + \hat{\sigma}_i^2/2) + \left\{ \left(\frac{Z_{i,\zeta/2} \hat{\sigma}_i^2}{n_{i(1)}} \right)^2 + \frac{\hat{\sigma}_i^4}{4} \left(\frac{n_{i(1)} - 1}{\chi_{i,\zeta/2, n_{i(1)} - 1}^2} - 1 \right)^2 \right\}^{1/2} \right]$$

149 Note that both $T_i = (n_{i(1)} - n_i \delta^*) / \sqrt{n_i \delta_i^* (1 - \delta_i^*)} \stackrel{d}{\sim} N(0, 1)$, and $Z_i = (\hat{\mu}_i - \mu_i) / \sqrt{\hat{\sigma}_i^2/n_{i(1)}} \stackrel{d}{\sim} N(0, 1)$ are
 150 independent random variables. According to Krishnamoorthy and Oral (2015), the $100(1 - \zeta)\%$ MOVER
 151 interval for ϑ is

$$\begin{aligned}
 CI_{\vartheta}^{(mover)} &= [L_{\vartheta}, U_{\vartheta}] \\
 &= \left[\frac{\sum_{i=1}^k w_i \hat{\vartheta}_i^{(Ait)}}{\sum_{i=1}^k w_i} - \sqrt{\frac{\sum_{i=1}^k w_i^2 (\hat{\vartheta}_i^{(Ait)} - L_{\vartheta_i})^2}{\sum_{i=1}^k w_i^2}}, \frac{\sum_{i=1}^k w_i \hat{\vartheta}_i^{(Ait)}}{\sum_{i=1}^k w_i} - \sqrt{\frac{\sum_{i=1}^k w_i^2 (\hat{\vartheta}_i^{(Ait)} - U_{\vartheta_i})^2}{\sum_{i=1}^k w_i^2}} \right]
 \end{aligned} \tag{25}$$

152 where $w_i = 1/\widehat{Var}[\hat{\vartheta}_i^{(Ait)}]$. Algorithm 3 describes the steps to construct the MOVER interval.

153 **Algorithm 3: MOVER**

- 154 1) Compute CIs for $\ln \delta_i^*$ and $\mu_i + \sigma_i^2$ are $(l_{\ln \delta_i^*}, u_{\ln \delta_i^*})$ and $(l_{\mu_i + \sigma_i^2}, u_{\mu_i + \sigma_i^2})$, respectively.
 155 2) Compute MOVER for ϑ_i , as given in (23).
 156 3) Compute 95%MOVER for ϑ , given in (25).

157 **Parametric Bootstrap**

158 This is developed from the parametric bootstrap on the common mean of several heterogeneous log-
 159 normal distributions, proposed by Malekzadeh and Kharrati-Kopaei (2019). The delta-lognormal mean is
 160 transformed by taking the logarithm as

$$\mu_i = \ln\left(\frac{\vartheta}{1 - \delta_i}\right) - \frac{\sigma_i^2}{2} \tag{26}$$

161 The likelihood of $(\vartheta, \sigma_i^2, \delta_i)$ is

$$L(\vartheta, \sigma_i^2, \delta_i | w_{ij}) = \prod_{i=1}^k \binom{n_i}{n_{i(0)}} \delta_i (1 - \delta_i) \frac{1}{(2\pi\sigma_i^2)^{n_{i(1)}/2}} \exp\left\{-\frac{1}{2\sigma_i^2} \sum_{j=1}^{n_{i(1)}} \left(\ln w_{ij} - \ln\left(\frac{\vartheta}{1 - \delta_i}\right) + \frac{\sigma_i^2}{2}\right)^2\right\} \tag{27}$$

162 which enables obtaining the maximum likelihood estimates of $\ln \vartheta$ and σ_i^2 as

$$\begin{aligned}
 \ln \hat{\vartheta}_{mle} &= \frac{\sum_{i=1}^k \hat{w}_{mle,i} [\hat{\mu}_i + \ln(1 - \hat{\delta}_i)] + N/2}{\sum_{i=1}^k \hat{w}_{mle,i}} \\
 \hat{\sigma}_{mle,i}^2 &= -2 + 2\sqrt{1 + \hat{\sigma}_i^2 + \{\hat{\mu} - \ln[\hat{\vartheta}/(1 - \hat{\delta}_i)]\}^2}
 \end{aligned} \tag{28}$$

163 where $\hat{w}_{mle,i} = n_{i(1)}/\hat{\sigma}_{mle,i}^2$ and $\ln \hat{\vartheta} = \frac{\sum_{i=1}^k \hat{w}_i [\hat{\mu}_i + \ln(1 - \hat{\delta}_i)] + N/2}{\sum_{i=1}^k \hat{w}_i}$; $\hat{w}_i = n_{i(1)}/\hat{\sigma}_i^2$. If $\delta_i = 0$, then it becomes the
 164 common lognormal mean (see Krishnamoorthy and Oral (2015) for a detailed explanation). By applying
 165 central limit theorem, we obtain $(\ln \hat{\vartheta}_{mle} - \ln \vartheta) \sqrt{\sum_{i=1}^k \hat{w}_{mle,i}} \sim N(0, 1)$ such that $T = (\ln \hat{\vartheta}_{mle} - \ln \vartheta)^2 \sum_{i=1}^k \hat{w}_{mle,i} \sim$
 166 $\chi_{n_{i(1)}-1}^2$. It is well-known that $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}_i$ are independent random variables for which $\hat{\mu}_i \sim N\left(\frac{\vartheta}{1 - \delta_i}\right) -$
 167 $\frac{\sigma_i^2}{2}$, $\sigma_i^2/n_{i(1)}$, $(n_{i(1)} - 1)\hat{\sigma}_i^2/\sigma_i^2 \sim \chi_{n_{i(1)}-1}^2$ and $\hat{\delta}_i \sim N(\delta, \delta(1 - \delta)/n_i)$ are obtained, respectively. Let
 168 $\eta = \mu_i + \sigma_i^2/2$ so that we can write $T = \frac{\sum_{i=1}^k \hat{w}_{mle,i} [\hat{\mu}_i + \ln(1 - \hat{\delta}_i) - \eta - \ln(1 - \delta_i)] + N/2}{\sum_{i=1}^k \hat{w}_{mle,i}}$. It can be seen that the dis-
 169 tribution of T is complicated, possibly depending on nuisance parameters σ_i^2 and δ_i , but not on $\ln \vartheta$.
 170 Thus, the exact distribution of T is unknown in practice, and so we propose the PB pivotal variable
 171 corresponding to T^{PB} as

$$T^{PB} = (\ln \hat{\vartheta}_{mle}^{PB} - \ln \hat{\vartheta})^2 \sum_{i=1}^k \hat{w}_{mle,i}^{PB} \tag{29}$$

172 where $\ln \hat{\vartheta}_{mle}^{PB} = \frac{\sum_{i=1}^k \hat{w}_{mle,i}^{PB} [\hat{\mu}_i^{PB} + \ln(1 - \hat{\delta}_i^{PB})] + N/2}{\sum_{i=1}^k \hat{w}_{mle,i}^{PB}}$, $\hat{w}_i^{PB} = n_{i(1)} / \hat{\sigma}_i^{2PB}$, $\hat{\mu}_i^{PB} \sim N(\hat{\mu}_i^B, \hat{\sigma}_i^{2PB} / n_{i(1)})$, $\hat{\sigma}_i^{2PB} \sim \hat{\sigma}_i^{B2} \chi_{n_{i(1)} - 1}^2$
 173 $/(n_{i(1)} - 1)$ and $\hat{\delta}_i^{PB} \sim \text{beta}(n_{i(0)}^B + 0.5, n_{i(1)}^B + 0.5)$, $n_{i(0)}^B = n_i \hat{\delta}_i^B$, and $n_{i(1)}^B = n_i - n_{i(0)}^B$. Note that $\hat{\mu}_i^B$, $\hat{\sigma}_i^{2B}$,
 174 and $\hat{\delta}_i^B$ are the observed values of $\hat{\mu}_i$, $\hat{\sigma}_i^2$, and $\hat{\delta}_i$, respectively, from random sampling with replacement
 175 based on the bootstrap approach. Thus, the $100(1 - \zeta)\%$ PB interval for ϑ is given by

$$CI_{\vartheta}^{(pb)} = \exp \left[\ln \hat{\vartheta}_{mle} \mp \sqrt{q_{\zeta}^{PB} / \sum_{i=1}^k \hat{w}_{mle,i}^{PB}} \right] \quad (30)$$

176 where q_{ζ}^{PB} denotes the $(1 - \zeta)^{th}$ percentile of distribution of T^{PB} . The PB interval can be constructed as
 177 shown in Algorithm 4.

178 **Algorithm 4: PB**

- 179 1) Compute $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}_i$ leading to obtain $\ln \hat{\vartheta}$.
- 180 2) Compute $\ln \hat{\vartheta}_{mle}$ and $\hat{\sigma}_{mle,i}^2$.
- 181 3) Generate $\hat{\mu}_i^{PB}$, $\hat{\sigma}_i^{2PB}$ and $\hat{\delta}_i^{PB}$ leading to compute $\ln \hat{\vartheta}_{mle}^{PB}$.
- 182 4) Repeat steps 1-3, a number of time $m = 2500$, compute T^{PB} to obtain q_{ζ}^{PB} .
- 183 5) Compute 95%PB interval for ϑ , as given in (30).

184 **Highest Posterior Density Intervals**

185 The HPD interval is constructed from the posterior distribution, as defined by Box and Tiao (1973). Note
 186 that the prior of ϑ_i is updated with its likelihood function thereby obtaining the posterior distribution
 187 based on the Bayesian approach. Recall that $W_{ij} \sim \Delta(\mu_i, \sigma_i^2, \delta_i)$, then the likelihood is given by

$$P(W_{ij} | \mu_i, \sigma_i^2, \delta_i) \propto \prod_{i=1}^k \delta_i^{n_{i(0)}} (1 - \delta_i)^{n_{i(1)}} (\sigma_i^2)^{-n_{i(1)}/2} \exp \left\{ -\frac{1}{2\sigma_i^2} \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \mu_i)^2 \right\} \quad (31)$$

188 For k individual samples, Miroshnikov et al. (2015) described the pooled independent sub-posterior
 189 samples toward the joint posterior distributions ϑ are combined using weighted averages as follows:

$$\vartheta^{post} = \sum_{i=1}^k w_i \vartheta_i^{post} \left(\sum_{i=1}^k w_i \right)^{-1} \quad (32)$$

190 where ϑ_i^{post} are the posterior samples of ϑ_i , for $i = 1, 2, \dots, k$. The inverse of the sample variance is used to
 191 weight the posterior based on the i^{th} samples is denoted as $w_i = \text{Var}^{-1}(\hat{\vartheta}_i | w_{ij})$. Different priors have been
 192 developed for estimating the common delta-lognormal mean, two of which are derived in the following
 193 subsections.

194 **Jeffreys' Rule Prior**

195 Harvey and van der Merwe (2012) defined this prior as

$$P(\vartheta)_{JR} \propto \prod_{i=1}^k \sigma_i^{-3} \delta_i^{-1/2} (1 - \delta_i)^{1/2} \quad (33)$$

196 which is combined with the likelihood (34) to obtain the posterior of ϑ as

$$\begin{aligned} P(W_{ij} | \vartheta) &\propto \prod_{i=1}^k \delta_i^{n_{i(0)} - 1/2} (1 - \delta_i)^{n_{i(1)} + 1/2} (\sigma_i^2)^{-(n_{i(1)} + 3)/2} \exp \left\{ -\frac{1}{2\sigma_i^2} \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \mu_i)^2 \right\} \\ &\propto \prod_{i=1}^k \delta_i^{(n_{i(0)} + 1/2) - 1} (1 - \delta_i)^{(n_{i(1)} + 3/2) - 1} (\sigma_i^2)^{-\frac{(n_{i(1)} + 1)}{2} - 1} \\ &\quad \exp \left\{ -\frac{1}{2\sigma_i^2} [(n_{i(1)} - 1) \hat{\sigma}_i^2 + n_{i(1)} (\hat{\mu}_i - \mu_i)^2] \right\} \end{aligned} \quad (34)$$

197 This leads to obtaining the marginal posterior distributions of μ_i , σ_i^2 and δ_i as

$$\begin{aligned}\mu_i^{(JR)} | \sigma_{i,JR}^2, w_{ij} &\sim N(\hat{\mu}_i, \sigma_i^{2(JR)} / n_{i(1)}) \\ \sigma_i^{2(JR)} | w_{ij} &\sim IG((n_{i(1)} + 1)/2, (n_{i(1)} + 1)\hat{\sigma}_i^2/2) \\ \delta_i^{(JR)} | w_{ij} &\sim \text{beta}(n_{i(0)} + 1/2, n_{i(1)} + 3/2)\end{aligned}\quad (35)$$

198 The pooled posterior of ϑ is weighted by its inversely estimated variance as follows:

$$\vartheta^{post} = \sum_{i=1}^k w_i^{(JR)} \vartheta_i^{(JR)p} \left(\sum_{i=1}^k w_i^{(JR)} \right)^{-1} \quad (36)$$

199 where

$$\begin{aligned}\vartheta_i^{(JR)p} &= (1 - \delta_i^{(JR)}) \exp(\mu_i^{(JR)} + \sigma_i^{2(JR)}/2) \\ w_i^{(JR)} &= \left\{ n_i^{-1} \exp(2\mu_i^{(JR)} + \sigma_i^{2(JR)}) \left[\delta_i^{(JR)} (1 - \delta_i^{(JR)}) + \frac{1}{2} (1 - \delta_i^{(JR)}) (2\sigma_i^{2(JR)} + \sigma_i^{4(JR)}) \right] \right\}^{-1}\end{aligned}$$

202 From (36), the 100(1 - ζ)%HPD-based Jeffreys' rule prior (HPD-JR) for ϑ is constructed as follows:

203 **Normal-Gamma-Beta Prior**

204 Maneerat et al. (2020) proposed a HPD based on the normal-gamma prior for the ratio of delta-lognormal
205 variances that worked better than the HPD-JR of Harvey and van der Merwe (2012). Suppose that
206 $\mathbf{Y} = \ln \mathbf{W}$ be a random variable of normal distribution with mean $\boldsymbol{\mu} = (\mu_1, \mu_2, \dots, \mu_k)$ and precision
207 $\boldsymbol{\lambda} = (\lambda_1, \lambda_2, \dots, \lambda_k)$ where $\mathbf{W} \sim LN(\boldsymbol{\mu}, \boldsymbol{\lambda})$ and $\lambda_i = \sigma_i^{-2}$. The HPD-based normal-gamma-beta prior (HPD-
208 NGB) of $\vartheta = (\mu_i, \lambda_i, \delta_i)'$ is defined as

$$P(\vartheta) \propto \prod_{i=1}^k \lambda_i^{-1} [\delta_i (1 - \delta_i)]^{-1/2} \quad (37)$$

209 where (μ_i, λ_i) follows a normal-gamma distribution, and δ_i follows a beta distribution, denoted as
210 $(\mu_i, \lambda_i) \sim NG(\mu_i, \lambda_i | \mu, k_{i(0)} = 0, \alpha_{i(0)} = -1/2, \beta_{i(0)} = 0)$ and $\delta_i \sim \text{beta}(1/2, 1/2)$, respectively. When the
211 the prior (37) is combined with the likelihood (34), then the posterior density of ϑ becomes

$$\begin{aligned}P(\vartheta | w_{ij}) &\propto \prod_{i=1}^k \delta_i^{n_{i(0)} - 1/2} (1 - \delta_i)^{n_{i(1)} - 1/2} \lambda_i^{\frac{n_{i(1)} - 1}{2} - 1} \exp \left\{ -\frac{\lambda_i}{2} \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \hat{\mu}_i)^2 \right\} \lambda_i^{1/2} \\ &\exp \left\{ -\frac{n_{i(1)} \lambda_i}{2} (\mu_i - \mu_i^*)^2 \right\}\end{aligned}\quad (38)$$

212 which can be integrated out to obtain the marginal posterior distributions of μ_i , λ_i and δ_i as follows:

$$\begin{aligned}\mu_i^{(NGB)} | w_{ij} &\sim t_{df} \left(\mu_i | \hat{\mu}_i, \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \hat{\mu}_i)^2 / [n_{i(1)}(n_{i(1)} - 1)] \right) \\ \lambda_i^{(NGB)} | w_{ij} &\sim G \left(\lambda_i | (n_{i(1)} - 1)/2, \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \hat{\mu}_i)^2 / 2 \right) \\ \delta_i^{(NGB)} | w_{ij} &\sim \text{beta}(n_{i(0)} + 1/2, n_{i(1)} + 1/2)\end{aligned}\quad (39)$$

213 where $df = 2(n_{i(1)} - 1)$ and $\sigma_i^{2(NGB)} | w_{ij} \sim IG(\sigma_i^2 | (n_{i(1)} - 1)/2, \sum_{j=1}^{n_{i(1)}} (\ln w_{ij} - \hat{\mu}_i)^2 / 2)$. Similarly, the
214 pooled posterior of ϑ is given by

$$\vartheta^{post} = \sum_{i=1}^k w_i^{(NGB)} \vartheta_i^{(NGB)p} \left(\sum_{i=1}^k w_i^{(NGB)} \right)^{-1} \quad (40)$$

215 where

$$216 \vartheta_i^{(NGB)p} = (1 - \delta_i^{(NGB)}) \exp(\mu_i^{(NGB)} + \sigma_i^{2(NGB)}/2)$$

$$217 w_i^{(NGB)} = \left\{ n_i^{-1} \exp(2\mu_i^{(NGB)} + \sigma_i^{2(NGB)}) \left[\delta_i^{(NGB)} (1 - \delta_i^{(NGB)})^{\frac{1}{2}} (1 - \delta_i^{(NGB)}) (2\sigma_i^{2(NGB)} + \sigma_i^{4(NGB)}) \right] \right\}^{-1}$$

218 Hence, the $100(1 - \zeta)\%$ HPD-HGB for ϑ is constructed in (40). Algorithm 5 details the steps to construct
219 the HPD-JR and HPD-NGB.

220 **Algorithm 5: HPD-JR and HPD-NGB**

- 221 1) Compute $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}$.
222 2) Generate the posterior densities of μ_i , σ_i^2 and δ_i based-Jeffreys' rule (JR) and normal-gamma-beta
223 (NGB) priors, as given in (35) and (39), respectively.
224 3) Compute the pooled posterior of ϑ based on JR and NGB priors, as given in (36) and (40),
225 respectively.
226 4) Compute 95%HPD-JR and HPD-NGB for ϑ , defined by Box and Tiao (1973).

227 **SIMULATION STUDIES AND RESULTS**

228 The performances of the CIs were assessed by comparing their coverage probabilities (CPs) and average
229 length (ALs) using Monte Carlo simulation. The best-performing CI is the one where the CP is closest
230 to or greater than the nominal confidence level $1 - \zeta$ while also having an AL with the narrowest width.
231 The CIs for the common delta-lognormal mean constructed using FGCI, LS, MOVER, PB, HPD-JR, and
232 HPD-NGB were assessed in the study, the parameter settings for which are provided in Table 1. The
233 number of generated random samples was fixed at $M = 5000$. For FGCI, the number of FGQs was
234 $Q = 2500$ for each set of 5000 random samples. Algorithm 6 shows the computational steps to estimate
235 the CP and AL performances of all of the methods.

Table 1. Parameter settings for sample cases $k = 2, 5, 10$.

Scenarios	(n_1, \dots, n_k)	$(\delta_1, \dots, \delta_k)$	$(\sigma_1^2, \dots, \sigma_k^2)$

121-126	(50 ₅ ,100 ₅)	(0.1 ₅ ,0.2 ₅), (0.2 ₅ ,0.5 ₅)	(1 ₅ ,2 ₅), (2 ₅ ,4 ₅), (3 ₅ ,5 ₅)

Note: (30₅) stands for (30,30,30,30,30).

236 **Algorithm 6: Comparison of CPs and ALs for all CIs.**

237 For $g = 1$ to M . Generate $w_{ij} \sim \Delta(\mu_i, \sigma_i^2, \delta_i)$.

238 Compute the unbiased estimates $\hat{\mu}_i$, $\hat{\sigma}_i^2$ and $\hat{\delta}$.

239 Compute the 95% CIs for ϑ based on FGCI, LS, MOVER, PB and the HPDs via Algorithms 1, 2, 3, 4
240 and 5, respectively.

241 Let $A_g = 1$ if ϑ falls within the intervals of FGCI, LS, MOVER, PB or the HPDs, else $A_g = 0$.

242 The CP and AL for each method are obtained by $CP = (1/M) \sum_{g=1}^M A_g$ and $AL = (U - L)/M$, respectively,
243 where U and L are the upper and lower confidence limits, respectively. (end g loop)

244

245 The numerical results for the CI performances are presented in terms of CP and AL for various
 246 sample cases. For $k = 2$ (Table 2 and Figure 1), FGCI performed well for small-to-moderate sample sizes,
 247 as well as for large σ_i^2 and a moderate-to-large sample size. HPD-NGB attained stable and the best CP
 248 and AL values for small σ_i^2 and a moderate-to-large sample size. MOVER and PB attained correct CPs
 249 but wider ALs than the other methods whereas LS and HPD-JR had lower CPs and narrower ALs. For
 250 $k = 5$ (Table 3 and Figure 2), there were only two methods producing better CPs than the other methods in
 251 the various situations: MOVER (small δ_i and σ_i^2) and PB (large δ_i and σ_i^2). Moreover, the results were
 252 similar for $k = 10$ (Table 4 and Figure 3).

253 As previously mentioned, our findings show that FGCI works well for small sample case because the
 254 FGCI of σ_i^2 might contain some weak points that affect the FGCI of μ_i as the sample case increases. For
 255 large sample sizes, MOVER was the best method for small σ^2 , which is possibly caused by the CI for
 256 $\mu_i + \sigma_i^2$. Meanwhile, the next best one was PB, which has the strong point of using a resampling technique
 257 to collect information about several populations even when the variance σ^2 is large.

AN EMPIRICAL APPLICATION

Daily rainfall data obtained from the Thai Meteorological Department (TMD) were divided into the northern, northeastern, central, and eastern regions, while the southern region was a combination of the data from the southeastern and southwestern shores. Due to the differences in the climate patterns and meteorological conditions in the five regions, we focused was on estimating the daily rainfall data in these regions by treating them as separate sets of observations rather than using the average rainfall for the whole of Thailand by pooling them and treating them as a single population. The daily rainfall amounts were recorded on August 5 and 9, 2019, which is in the middle of the rainy season (mid-May to mid-October) when rice farming is conducted in Thailand. Entries with rainfall of less than 0.1 mm were considered as zero records.

Tables 5-6 contain the daily rainfall records for the five regions, while Figures 4-5 show histogram plots of rainfall observations, and Figures 6-7 exhibit normal Q-Q plots of the log-positive rainfall data on August 5 and 9, 2019, respectively. It can be seen that the data for all of the regions contained zero observations. After that, the fitted distribution of the positive observations was checked using the Akaike information criterion (AIC), as reported in Table 7. It can be concluded that the rainfall data in all of the regions on August 5 and 9, 2019 follow a delta-lognormal distribution. All data sets and R code are available in the Supplemental Files. The summary statistics are reported in Table 8. In the approximation of the daily rainfall amounts in the five regions, the estimated common means were 4.4506 and 13.2621 mm/day on August 5 and 9, 2019, respectively. The computed 95% CIs of the common rainfall mean are reported in Table 9. Under the rain criteria issued by the TMD (Department, 2018), it can be interpreted that the daily rainfall in Thailand on August 5, 2019, was light (0.1–10.0 mm), while it was moderate (10.1–35.0 mm) on August 9, 2019. These results confirm the simulation results for $k = 5$ in the previous section.

DISCUSSION

It can be seen that for MOVER and PB developed from the studies of Krishnamoorthy and Oral (2015) and Malekzadeh and Kharrati-Kopaei (2019), respectively, the simulation results are similar to both of these studies provided that the zero observations are omitted. CIs for the common mean have been investigated in both normal and lognormal distributions (Fairweather, 1972; Jordan and Krishnamoorthy, 1996; Krishnamoorthy and Mathew, 2003; Lin and Lee, 2005; Tian and Wu, 2007; Krishnamoorthy and Oral, 2015). However, the common mean of delta-lognormal populations is especially of interest because

288 it can be used to fit the data from real-world situations such as investigating medical costs (Zou et al.,
 289 2009; Tierney et al., 2003; Tian, 2005), analyzing airborne contaminants (Owen and DeRouen, 1980;
 290 Tian, 2005) and measuring fish abundance (Fletcher, 2008; Wu and Hsieh, 2014). Furthermore, it is
 291 possible that some extreme rainfall data also fulfill the assumptions of a delta-lognormal distribution.
 292 Note that such natural disasters as floods and landslides have been caused by the extreme rainfall events,
 293 as evidenced in many country around the world: Europe (e.g. Northern England, Southern Scotland and
 294 Ireland (Otto and Oldenborgh, 2017)), Asia (e.g. Japan (Oldenborgh, 2018)) and North America (e.g.
 295 Southeast Texas (Oldenborgh et al., 2019)). Our findings show that some of the methods studied had CPs
 296 that were too low or too high for large sample cases, a shortcoming that should be addressed in future
 297 work.

298 CONCLUSIONS

299 The objective of this study was to propose CIs for the common mean of several delta-lognormal dis-
 300 tributions using FGCI, LS, MOVER, PB, HPD-JR, and HPD-NGB. The CP and AL as performance
 301 measures of the methods were assessed via Monte Carlo simulation. The findings confirm that for small
 302 sample case ($k = 2$), FGCI and HPD-NGB are the recommended methods in different situations: FGCI
 303 (a small-to-moderate sample size and a large σ_i^2 with a moderate-to-large sample size) and HPD-NGB
 304 (small σ_i^2 with a moderate-to-large sample size). For large sample cases ($k = 5, 10$), MOVER (small δ_i
 305 and σ_i^2) and PB (large δ_i and σ_i^2) performed the best.

306 ACKNOWLEDGMENTS

307 The authors are grateful to the academic editor and reviewers for their constructive comments and
 308 suggestions which help to improve this manuscript.
