Abstract

Background. Coronary heart disease (CHD) is the leading cause of morbidity and mortality among elderly individuals. Patients with CHD are at high risk for mental health disorders, and psychological issues may affect the quality of life (QoL) of these patients. Nevertheless, there is little evidence regarding the psychological issues and QoL of patients with CHD among the elderly population. This study aimed to investigate the relationship between comorbidities and mental status as well as QoL among elderly patients with CHD.

Methods. Overall, 216 patients were included in this cross-sectional, observational, single-center study. The demographics and clinical manifestations of the patients were collected from electronic medical records. All patients were interviewed using the Chinese version of Symptom Checklist 90 (SCL-90) to assess the mental health status and the World Health Organization Quality of Life-BREF questionnaire (WHOQOL-BREF) to assess the QoL.

Results. In total, 96 men and 120 women, with a mean age of 71.69±8.30 years, were included. When controlling for the patients' sex, marital status and stroke, multiple stepwise linear regression analyses suggested that for CHD patients, comorbid type 2 diabetes mellitus had the significant influence on average positive factors (Coef., 5.809; 95% CI: 2.467, 9.152; p=0.001); when controlling for the patients' sex, marital status and type 2 diabetes mellitus, multiple stepwise linear regression analyses suggested that for CHD patients, comorbid stroke had the significant influence on average positive factors (Coef., 8.680; 95% CI: 4.826, 12.534; p <0.001); when controlling for the patients' sex, marital status, type 2 diabetes mellitus and

41 stroke, multiple stepwise linear regression analyses suggested that for CHD patients, comorbid
42 primary hypertension had the significant influence on phobic anxiety (Coef., 0.178; 95% CI:
43 0.010, 0.347; *p*=0.038).
44 **Conclusions.** For elderly CHD patients, comorbid type 2 diabetes mellitus and stroke were at
45 risk for psychological problems and lower QoL. Our findings may guide patients and clinicians
46 to make better decisions and achieve better outcomes.
47
48 Introduction
49 Coronary heart disease (CHD) is the leading cause of death worldwide(Wang et al. 2016). The
50 incidence and prevalence of CHD increase greatly with age(Kattainen et al. 2006). Therefore,
51 CHD is the major cause of morbidity and mortality among elderly individuals, which contributes
52 to a substantial economic burden on the healthcare system(Hanna & Wenger 2005). Patients with
53 CHD are at high risk for mental health disorders, such as depression and anxiety(Bashiri et al.
54 2016), which have both been strongly related to adverse outcomes in patients with CHD(Barth et
55 al. 2004). These psychological problems may not only increase the use of healthcare services,
56 but they also result in disease deterioration(Dehdari et al. 2009). In addition, CHD had a severe
57 impact on the quality of life (QoL)(Dyer et al. 2010). A previous study has shown that most of
58 the elderly population has three or more comorbid illnesses(Caughey et al. 2008). As people age,
59 the risk of chronic conditions increases, such as diabetes, heart disease, cancer and arthritis(Wu
60 et al. 2013). Previous research suggested a higher incidence of coexisting diseases in elderly
61 patients, and cardiovascular comorbidities and metabolic diseases were commonly encountered
62 diseases(Man in't Veld 1998; Van den Akker et al. 1998).Comorbidity is related to a decline in
63 many health outcomes including QoL and psychological distress, which increases the use of
64 health care resources(Fortin et al. 2006a; Fortin et al. 2006b; Wolff et al. 2002). However, until
65 now, there have been few studies that investigated the psychological issues and QoL of elderly
66 CHD patients, and the psychological states and QoL of elderly CHD patients are not clear.
67 Therefore, correlational studies are needed.
68
69 The SCL-90 is a widely used, self-rating questionnaire that contains multidimensional subscales
70 to measure overall health status. This scale contains 90 items, using 10 factors, to evaluate the
71 psychiatric symptoms in 10 aspects, which is regarded as a widely used psychological
72 measurement in China and several studies have assessed the validity of this instrument(Zhao et
73 al. 2019). The SCL-90 contains a very broad range of psychiatric symptomatology involving
74 feelings, emotion, thinking, consciousness, behavior, lifestyle, interpersonal relationships, diet
75 and sleep(Wei et al. 2018).
76
77 QoL is an increasingly important health issue in healthcare intervention(Al-Taie et al. 2019). The
78 WHOQOL-BREF is a short version of the WHOQOL-100, which is a rapid tool for the
79 assessment of QoL in clinical studies(Skevington et al. 2004). The properties of this
80 questionnaire have been tested and verified for evaluation in diverse cultural groups(Skevington

81 et al. 2004), which has suggested that it is a valid assessment with higher cross-cultural
82 applicability and it is widely recognized.
83
84 Patient self-rating health status measurements may be a useful tool to screen high-risk patients to
85 target for more efficient preventative measures, interventions and treatments in clinical
86 practice(Spertus et al. 2002). Due to the adequate reliability and validity of above two scales, we
87 used a Chinese version of SCL-90 to assess the mental health status and the WHOQOL-BREF
88 questionnaire to assess the QoL in patients with CHD, and we conducted a cross-sectional study
89 to investigate the relationship between the comorbidities and mental health status as well as QoL
90 among elderly patients with CHD.
91

Materials & Methods

93 *Study Design*
94 This cross-sectional, observational, single-center study was designed to investigate the
95 association between the type of comorbidities and mental status as well as QoL among elderly
96 patients with CHD. This study was approved by the China Ethics Committee of Registering
97 Clinical Trials (number, ChiECRCT-2017046) and registered with the Chinese Clinical Trial
98 Registry (number, ChiCTR1900021276). Informed consent was obtained from all patients.
99

100 *Study setting and subjects*
101 All subjects of this study were screened as inpatients who were hospitalized in the Department of
102 Cardiology and Geriatrics at Shanghai Ninth People's Hospital, Shanghai Jiao Tong University
103 School of Medicine, between February 2017 and January 2018. A total of 216 patients with a
104 prior diagnosis of CHD (International Classification of Diseases 10: codes I20–I25) were
105 enrolled. The inclusion criteria were those aged≥60 years, with a prior diagnosis of CHD. The
106 exclusion criteria were patients aged under 60 years, those with organic psychosis, those who
107 refused to give informed consent and who were unable to complete the scale. When patients of
108 the study were hospitalized more than once during the study period, we only used the first record
109 of that time to avoid double counting.
110

111 *Procedures and assessment methods*
112 The purpose of the cross-sectional trial was to assess the mental health status and QoL in elderly
113 patients with CHD. A face-to-face interview was performed for each patient in a private meeting
114 room. All interviews were made by the same doctor who received related training. All patients
115 were interviewed using the Chinese version of SCL-90 to assess the mental health status, and the
116 WHOQOL-BREF questionnaire assessed QoL. The demographic characteristics and clinical
117 manifestations of the patients, such as age, gender, height, weight, body mass index (BMI),
118 marital status and concomitant diseases, were collected from electronic medical records, and
119 these characteristics were verified by the patients during the interview.
120

121 SCL-90 was comprised of 90 items which consisted of 10 factors, including somatization (12
122 items), obsessive-compulsive (10 items), interpersonal sensitivity (9 items), depression (13
123 items), anxiety (10 items), hostility (6 items), phobic anxiety (7 items), paranoid ideation (6
124 items), psychoticism (10 items) and other factors (sleep and diet, 7 items). Each item was scored
125 using a 5-point scale (0=none, 1=slight, 2=mild, 3=moderate, 4=severe). This questionnaire
126 indicated a positive item was with a score of more than 2, which may suggest potential mental
127 health issues for that aspect. A higher score of average positive factors indicated a more severe
128 psychological problem(Wei et al. 2018).
129
130 The WHOQOL-BREF is a widely used tool that has adequate reliability and validity to assess
131 the QoL. The WHOQOL-BREF questionnaire has 26 items including two general items and 24
132 items, and 24 items to evaluate four main domains of the QoL, which referred to the physical
133 status(7 items), psychological health(6 items), social relations(3 items), and environmental
134 factors(8 items)(Ohaeri & Awadalla 2009). Each item is scored using a five-point scale ranging
135 from 1 (very dissatisfied or very poor) to 5 (very satisfied or very good). Mean scores of items
136 are multiplied by four to make domain scores ranging from 4 to 20. And scores of the two
137 general items also range from 4 to 20, respectively.
138
139 ***Study variables***
140 The parameters, including demographic characteristics, clinical manifestations, concomitant
141 comorbidities and the scores of the two assessment scales, were evaluated in the 216 patients
142 with CHD. CHD with comorbidity of primary hypertension, type 2 diabetes mellitus and stroke,
143 respectively, was analyzed. A set of the following clinical parameters was analyzed: age, sex,
144 height, weight, BMI, marital status, presence of primary hypertension, presence of type 2
145 diabetes mellitus, presence of stroke, average positive factors and nine factors of SCL-90 scale,
146 the scores of four domains of the WHOQOL-BREF scale.
147
148 ***Statistical analysis***
149 Data were shown as number (%) or as mean (standard deviation). The t test was used for the
150 continuous variables. The associations were examined using multiple stepwise linear regression
151 analyses, and variables including age, sex, BMI, marital status, primary hypertension, type 2
152 diabetes mellitus and stroke were entered into the multiple stepwise linear regression. We used
153 multiple stepwise linear regression analyses to generate significant fit models. The coefficients
154 and 95% confidence interval (CI) for each significant variable were determined. A *p*-value of
155 <0.05 was considered statistically significant. Statistical analyses were performed using IBM
156 SPSS 24.0.
157

Results
159 In total, 96 men and 120 women, with a mean age of 71.69(8.30) years, were included. Among
160 the 216 patients, 209 (96.8%) patients were married, and 7 (3.2%) patients were widowed or

161   bachelors. Patients had a mean height of 165.80(8.27) cm, a mean weight of 70.78(9.01) kg, and
162   a mean BMI of 25.71(2.32) kg/m². The demographic characteristics of elderly patients with CHD
163   are presented in Table 1.
164
165   In univariate analysis, the mean number of positive factors were 26.18 (14.88) and 20.69 (9.54)
166   for participants with and without primary hypertension, respectively (p=0.003); the mean scores
167   of WHOQOL-BREF physical domain were 12.43 (2.82) and 13.58 (2.08) for participants with
168   and without primary hypertension, respectively (p=0.003). The mean number of positive factors
169   were 29.54 (14.97) and 22.23 (12.79) for participants with and without type 2 diabetes mellitus,
170   respectively (p <0.001); the mean scores of WHOQOL-BREF physical domain were 11.74
171   (2.90) and 13.25 (2.44) for participants with and without type 2 diabetes mellitus, respectively (p
172   <0.001); the mean scores of WHOQOL-BREF psychological domain were 12.93 (2.42) and
173   13.85 (2.22) for participants with and without type 2 diabetes mellitus, respectively (p=0.005).
174   The mean number of positive factors were 33.24 (15.66) and 22.57 (12.63) for participants with
175   and without stroke, respectively (p <0.001); the mean scores of WHOQOL-BREF physical
176   domain were 11.31 (2.96) and 13.08 (2.51) for participants with and without stroke, respectively
177   (p <0.001); the mean scores of WHOQOL-BREF psychological domain were 12.84 (2.72) and
178   13.70 (2.18) for participants with and without stroke, respectively (p=0.022).The results of
179   univariate analyses are shown in Supplementary Tables 1, 2, and 3.
180
181   Multiple stepwise linear regression analyses suggested that for CHD patients, when controlling
182   for the patients' sex, marital status and stroke, comorbid type 2 diabetes mellitus had the
183   significant influence on average positive factors (Coef., 5.809; 95% CI: 2.467, 9.152; p=0.001),
184   interpersonal sensitivity (Coef., 0.151; 95% CI: 0.033, 0.270; p=0.012), depression (Coef.,
185   0.241; 95% CI: 0.100, 0.381; p=0.001), anxiety (Coef., 0.151; 95% CI: 0.035, 0.268; p=0.011),
186   psychoticism (Coef., 0.146; 95% CI: 0.045, 0.247; p=0.005), physical domain (Coef., -1.272;
187   95% CI: -1.953, -0.591; p <0.001); when controlling for the patients' sex and stroke, comorbid
188   type 2 diabetes mellitus had the significant influence on somatization (Coef., 0.346; 95% CI:
189   0.159, 0.533; p <0.001); when controlling for the patients' age, marital status and stroke,
190   comorbid type 2 diabetes mellitus had the significant influence on hostility (Coef., 0.128; 95%
191   CI: 0.015, 0.242; p=0.027); when controlling for the patients' sex, marital status, stroke and
192   primary hypertension, comorbid type 2 diabetes mellitus had the significant influence on phobic
193   anxiety (Coef., 0.165; 95% CI: 0.025, 0.305; p=0.021); when controlling for the patients' marital
194   status and stroke, comorbid type 2 diabetes mellitus had the significant influence on paranoid
195   ideation (Coef., 0.097; 95% CI: 0.003, 0.192; p=0.044); when controlling for the patients' sex
196   and marital status, comorbid type 2 diabetes mellitus had the significant influence on
197   psychological domain (Coef., -0.855; 95% CI: -1.477, -0.234; p=0.007).
198
199   Multiple stepwise linear regression analyses suggested that for CHD patients, when controlling
200   for the patients' sex, marital status and type 2 diabetes mellitus, comorbid stroke had the

201 significant influence on average positive factors (Coef., 8.680; 95% CI: 4.826, 12.534; *p*
202 *<0.001*), interpersonal sensitivity (Coef., 0.232; 95% CI: 0.096, 0.368; *p*=0.001), depression
203 (Coef., 0.401; 95% CI: 0.239, 0.563; *p <0.001*), anxiety (Coef., 0.143; 95% CI: 0.009, 0.278;
204 *p*=0.037), psychoticism (Coef., 0.305; 95% CI: 0.189, 0.422; *p <0.001*), physical domain (Coef.,
205 -1.416; 95% CI: -2.202, -0.631; *p <0.001*); when controlling for the patients' sex and type 2
206 diabetes mellitus, comorbid stroke had the significant influence on somatization (Coef., 0.356;
207 95% CI: 0.141, 0.572; *p* =0.001); when controlling for the patients' sex and marital status,
208 comorbid stroke had the significant influence on obsessive-compulsive (Coef., 0.308; 95% CI:
209 0.162, 0.453; *p* <0.001); when controlling for the patients' age, marital status and type 2 diabetes
210 mellitus, comorbid stroke had the significant influence on hostility (Coef., 0.168; 95% CI: 0.032,
211 0.304; *p*=0.016); when controlling for the patients' sex, marital status, type 2 diabetes mellitus
212 and primary hypertension, comorbid stroke had the significant influence on phobic anxiety
213 (Coef., 0.320; 95% CI: 0.162, 0.479; *p <0.001*); when controlling for the patients' marital status
214 and type 2 diabetes mellitus, comorbid stroke had the significant influence on paranoid ideation
215 (Coef., 0.214; 95% CI: 0.105, 0.323; *p <0.001*);
216
217 When controlling for the patients' sex, marital status, type 2 diabetes mellitus and stroke,
218 multiple stepwise linear regression analyses suggested that for CHD patients, comorbid primary
219 hypertension had the significant influence on phobic anxiety (Coef., 0.178; 95% CI: 0.010,
220 0.347; *p*=0.038). The relationship between scores of the two scales and three comorbidities is
221 presented in Tables 2 and 3.
222

223 **Discussion**
224 Our findings suggested that for CHD patients, comorbid type 2 diabetes mellitus was positively
225 associated with higher scores in average positive factors, somatization, interpersonal sensitivity,
226 depression, anxiety, hostility, phobic anxiety, paranoid ideation and psychoticism, respectively;
227 while comorbid stroke was positively associated with higher scores in average positive factors,
228 somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility,
229 phobic anxiety, paranoid ideation, psychoticism, respectively; comorbid primary hypertension
230 was positively associated with higher scores in phobic anxiety; higher scores represented
231 potential mental health issues. Therefore, the presence of these comorbidities resulted in poorer
232 mental health among elderly patients with CHD. On the other hand, for CHD patients, comorbid
233 type 2 diabetes mellitus was negatively associated with scores of the physical and psychological
234 domain; comorbid stroke was negatively associated with scores of the physical domain. Our
235 results suggested that with comorbidity of these comorbidities resulted in a lower QoL among
236 elderly patients with CHD. To the best of our knowledge, this is the first study to examine the
237 association between the type of comorbidities and mental health status and QoL among elderly
238 patients with CHD.
239

240 A previous study reported that co-existing psychological problems were more harmful than a
241 single psychological problem for patients with several basic diseases(Pincus et al. 2004).
242 Multidimensional psychological assessment can aid clinicians to comprehensively and better
243 understand the symptoms and mental health status of patients(Helzer et al. 2009). In our study,
244 we used the SCL-90 scale to assess psychological status, which was commonly used in
245 psychiatric and psychological counseling clinics to evaluate the psychological statuses and
246 mental issues among people having different occupations(Wei et al. 2018). Several previous
247 studies demonstrated a link between depression and CHD(Reid et al. 2013), diabetes(Goins et al.
248 2019), as well as age(Reid et al. 2013). Besides, mental health disorders are common in patients
249 with stroke(Almeida & Xiao 2007). Similarly, our findings demonstrated that for elderly CHD
250 patients, comorbid type 2 diabetes mellitus or stroke was associated with a higher SCL-90 score;
251 however, further studies with larger samples of patients are necessary to verify our findings.
252 Additionally, in this population, hypertension influenced the factor of phobic anxiety, which may
253 be a useful basis for further research as few studies focus on the comorbidities of elderly
254 patients. Being informed of mental health status might be useful in screening mental health
255 needs, which can guide health care interventions(Moriarty et al. 2009). Our study adopted the
256 multidimensional to assess the different aspects of mental health in elderly CHD patients with
257 comorbidities, which may be a useful basis for clinical practice.
258
259 CHD had a severe impact on human health and QoL(Dyer et al. 2010); therefore, QoL was an
260 important predictor of health outcomes in CHD treatment(Cepeda-Valery et al. 2011). CHD
261 patients had a lower QoL, which may be affected by psychological symptoms(Raymakers et al.
262 2018; Saengsiri et al. 2014). Besides, published studies indicated that comorbidities may affect
263 the elderly patients' QoL(Jacobs 2009; Rambod et al. 2020), and our study indicated that for
264 elderly CHD patients, comorbid type 2 diabetes mellitus was negatively associated with the
265 scores of the WHOQOL-BREF physical and psychological domains. Therefore, comorbid type 2
266 diabetes mellitus negatively affected the QoL, which was consistent with previous
267 studies(Marfella et al. 2018; Sardu et al. 2019). A published study showed that cognitive
268 function was a predictor of the physical function domain of health-related QoL(Patel et al. 2007).
269 Also, psychological problems, such as anxiety and depression, are common in stroke patients(De
270 Wit et al. 2017; Froes et al. 2011). Furthermore, our study indicated that comorbid stroke was
271 negatively associated with the scores of the WHOQOL-BREF physical domain, which was
272 consistent with previous studies. In addition, our study suggested that for elderly CHD patients,
273 comorbid primary hypertension did not significantly influence the scores of WHOQOL-BREF
274 domains. Comorbidity was an important factor in health-related QoL deterioration associated
275 with aging, and it should be noted that comorbidity can affect different domains of QoL to
276 varying degrees(Zygmuntowicz et al. 2012). Our findings may serve as a piece of evidence in
277 health care.
278

279 There are some limitations to our study. First, our study was limited by its observational nature.
280 The data were from a single hospital, and the sample was relatively small. Second, this was a
281 cross-sectional study in which we identified the relationship between the scores of two scales and
282 the type of comorbidities; however, longitudinal studies are needed to examine the relationship
283 over time(AlRuthia et al. 2020). Finally, this is a questionnaire-based survey, and the results
284 might have been negatively affected by acquiescence bias, social desirability bias, and
285 interviewer bias(Bowling 2005). Moreover, there might have been recall bias in elderly patients
286 with a decline in memory. The self-rating questionnaire may result in an additional form of bias
287 (Murphy et al. 2014).
288

289 ## Conclusions
290 In this study, we studied the association between the types of comorbidities among elderly
291 patients with CHD and mental health and QoL. The results suggested that for elderly CHD
292 patients, comorbid type 2 diabetes mellitus were more likely to exist with psychological
293 problems and lower QoL than the population without type 2 diabetes mellitus. In addition, our
294 study suggested that comorbid stroke affected mental health and QoL in the target population.
295 These findings may guide patients and clinicians to make better decisions and help this
296 population to achieve better outcomes.
