Background. The flea toad *Brachycephalus sulfuratus* was recently described from southeastern and southern Brazil. In its description, the authors overlooked previous identifications of flea toads as *Brachycephalus* sp. nov. and *B. hermogenesi* occurring in the same regions, which could suggest the possibility of three flea toads coexisting in southern Brazil. In addition, *B. sulfuratus* is characterized by substantial phenotypic variability, to an extent that compromises its current diagnosis with respect to its congener *B. hermogenesi*. Therefore, the current state-of-affairs regarding the geographical distribution of these two species and the identification of previously known populations is hitherto uncertain. Our goals are to reassess previous records of flea toads attributable to *B. hermogenesi*, *B. sulfuratus*, and *Brachycephalus* sp. nov., considering the description of *B. sulfuratus*, and to review the distinction of *B. sulfuratus*. **Methods.** A critical analysis of the species identity of specimens attributable to *B. hermogenesi*, *B. sulfuratus* or to a similar, potentially undescribed, flea toads from southeastern and southern Brazil was based either on the analysis of morphology or on their advertisement calls. This analysis includes our independent examinations of specimens and, when impossible, critical examinations of published descriptions. **Results.** We found that morphological and call traits originally proposed as diagnostic for *B. sulfuratus* in relation to *B. hermogenesi* vary intraspecifically. Live individuals with ventral yellow spots correspond to *B. sulfuratus*; individuals without yellow spots can be either *B. sulfuratus* or *B. hermogenesi*. In preservative, they are indistinguishable. Previous records of *Brachycephalus* sp. nov. correspond to *B. sulfuratus*. We propose the highest number of pulses per note of the call of *B. sulfuratus* as the only diagnostic trait in relation to *B. hermogenesi*. Regarding their distributions based in our revision, only *B. sulfuratus* occurs

in southern Brazil, without any overlap with *B. hermogenesi*. There is a narrow gap between the distributions of these species around the southeast of the city of São Paulo. Biogeographic events might have led to vicariance are discussed.

25

26

27 **Abstract**

28 **Background.** The flea toad *Brachycephalus sulfuratus* was recently described from southeastern
29 and southern Brazil. In its description, the authors overlooked previous identifications of flea
30 toads as *Brachycephalus* sp. nov. and *B. hermogenesi* occurring in the same regions, which could
31 suggest the possibly of three flea toads coexisting in southern Brazil. In addition, *B. sulfuratus* is
32 characterized by substantial phenotypic variability, to an extent that compromises its current
33 diagnosis with respect to its congener *B. hermogenesi*. Therefore, the current state-of-affairs
34 regarding the geographical distribution of these two species and the identification of previously
35 known populations is hitherto uncertain. Our goals are to reassess previous records of flea toads
36 attributable to *B. hermogenesi*, *B. sulfuratus*, and *Brachycephalus* sp. nov., considering the
37 description of *B. sulfuratus*, and to review the distinction of *B. sulfuratus*.

38 **Methods.** A critical analysis of the species identity of specimens attributable to *B. hermogenesi*,
39 *B. sulfuratus* or to a similar, potentially undescribed, flea toads from southeastern and southern
40 Brazil was based either on the analysis of morphology or on their advertisement calls. This
41 analysis includes our independent examinations of specimens and, when impossible, critical
42 examinations of published descriptions.

43 **Results.** We found that morphological and call traits originally proposed as diagnostic for *B.*
44 *sulfuratus* in relation to *B. hermogenesi* vary intraspecifically. Live individuals with ventral
45 yellow spots correspond to *B. sulfuratus*; individuals without yellow spots can be either *B.*
46 *sulfuratus* or *B. hermogenesi*. In preservative, they are indistinguishable. Previous records of
47 *Brachycephalus* sp. nov. correspond to *B. sulfuratus*. We propose the highest number of pulses
48 per note of the call of *B. sulfuratus* as the only diagnostic trait in relation to *B. hermogenesi*.
49 Regarding their distributions based in our revision, only *B. sulfuratus* occurs in southern Brazil,
50 without any overlap with *B. hermogenesi*. There is a narrow gap between the distributions of
51 these species around the southeast of the city of São Paulo. Biogeographic events might have led
52 to vicariance are discussed.

53

54

55 Introduction

56 Species of the *Brachycephalus didactylus* species group, commonly known as flea toads,
57 are distributed throughout much the Atlantic Forest of Brazil (Bornschein, Pie & Teixeira
58 2019a). The first described flea toad was *B. didactylus*, in 1971 (Izecksohn 1971) as the only
59 member of a new genus, *Psyllophryne*. The second flea toad species, *B. hermogenesi*, was
60 described nearly three decades later, in 1998 (Giaretta & Sawaya 1998), at the time as the second
61 species of the genus *Psyllophryne*. Recently, other two flea toads were described, namely *B.*
62 *pulex* (Napoli et al. 2011) and *B. sulfuratus* (Condez et al. 2016). All members of the *B.*
63 *didactylus* species group (*sensu* Ribeiro et al. 2015; Bornschein, Pie & Teixeira 2019a) are
64 distinguished by the leptodactyliform body shape and the absence of dermal ossification. The
65 remaining groups within *Brachycephalus* include the *B. ephippium* species group, with
66 bufoniform body shape and presence of dermal ossification, and the *B. pernix* species group,
67 equally with bufoniform body shape but without dermal ossification, as in the *B. didactylus*
68 species group (Ribeiro et al. 2015).

69 Only recently have flea toads been recorded in southern Brazil. The first records were of
70 *B. hermogenesi* to the Reserva Particular do Patrimônio Natural Salto Morato, municipality of
71 Guaraqueçaba, in the northern coast of Paraná (Pereira et al. 2010, Santos-Pereira et al. 2011),
72 and at Colônia Castelhanos, municipality of Guaratuba, in southern Paraná, initially as
73 “*Brachycephalus* aff. *hermogenesi*” (Cunha et al. 2010) and later as “*B. hermogenesi*” (Oliveira
74 et al. 2011). Just a few years later, Pie et al. (2013) published 14 localities of a flea toad
75 identified as *Brachycephalus* sp. nov. 1, from Paraná and Santa Catarina. These authors also
76 reidentified the record from Colônia Castelhanos as *Brachycephalus* sp. nov. 1. Records from
77 Reserva Particular do Patrimônio Natural Salto Morato of Pereira et al. (2010) and Santos-
78 Pereira et al. (2011) were inadvertently omitted from Pie et al (2013). Later, Bornschein et al.
79 (2016a) compiled 18 localities of a flea toad as *Brachycephalus* sp. 1., including the 14 records
80 of Pie et al. (2013) treated as *Brachycephalus* sp. nov. 1. Bornschein et al. (2016a) also
81 reidentified previous records of the flea toad of the Reserva Particular do Patrimônio Natural
82 Salto Morato and Colônia Castelhanos as *Brachycephalus* sp. 1.

83 The flea toad *B. sulfuratus* was described based on a series of 28 specimens distributed
84 from southern São Paulo to northern Santa Catarina (Condez et al. 2016). In that study, previous
85 records of *Brachycephalus* sp. nov. 1 from Pie et al. (2013) and *Brachycephalus* sp. 1 from

86 Bornschein et al. (2016a) were omitted and the opinion of Condez et al. (2016) related to this
87 alleged new species of flea toad is unknown. Condez et al. (2016) considered the presence of the
88 flea toad *B. hermogenesi* in Paraná, based on Cunha et al. (2010) and Oliveira et al. (2011).
89 However, the voucher specimen of Cunha et al. (2010) and Oliveira et al. (2011), a single
90 specimen deposited in the Museu de História Natural, Universidade Estadual de Campinas,
91 Campinas (ZUEC 16602), was reidentified by Condez et al. (2016) as *B. sulfuratus*. Remaining
92 records of *B. hermogenesi* in Paraná, from Pereira et al. (2010) and Santos-Pereira et al. (2011),
93 were overlooked by Condez et al. (2016).

94 An additional important aspect is the fact that one occurrence record of a flea toad in
95 Santa Catarina, called Castelo dos Bugres, provide specimens identified as *B. sulfuratus* (Condez
96 et al. (2016), *Brachycephalus* sp. 1. (Bornschein et al. 2016a), and *Brachycephalus* sp. nov. 1
97 (Pie et al. 2013). By overlooking specimens from this locality, Condez et al. (2016) missed the
98 opportunity to determine if it was conspecific with their newly described *B. sulfuratus*. At this
99 moment, the uncertainty in the identification of some important occurrence records seems to
100 indicate three possible scenarios. First, one could envision that there are three similar species of
101 flea toads in southern Brazil, namely *B. hermogenesi* (Pereira et al. 2010, Santos-Pereira et al.
102 2011), *Brachycephalus* sp. nov. (Pie et al. 2013, Bornschein et al. 2016a), and *B. sulfuratus*
103 (Condez et al. 2016). Second, records of *B. hermogenesi* in southern Brazil could be erroneous,
104 given that some of these records (Cunha et al. 2010, Oliveira et al. 2011) were assigned to *B.*
105 *sulfuratus* or *Brachycephalus* sp. nov. (Pie et al. 2013, Condez et al. 2016), leading to an
106 expectation that two species might occur in these regions (*B. sulfuratus* and *Brachycephalus* sp.
107 nov.). Third, if the new unnamed species identified by Pie et al. (2013) and Bornschein et al.
108 (2016a) is conspecific with *B. sulfuratus*, because the situation verified at Castelo dos Bugres,
109 there would be a single species of flea toad in southern Brazil (*B. sulfuratus*).

110 Recently, Bornschein, Pie & Teixeira (2019a) reviewed the available occurrence records
111 of flea toads from southeastern and southern Brazil and reverted most of the records of
112 “*Brachycephalus* sp. nov. 1” (Pie et al. 2013), “*Brachycephalus* sp. 1” (Bornschein et al. 2016a),
113 and *B. hermogenesi* from southern Brazil (Pereira et al. 2010, Santos-Pereira et al. 2011, 2016) in
114 favor of *B. sulfuratus*. Some records that could not be adequately reassessed by Bornschein, Pie
115 & Teixeira (2019a) were reverted to “*Brachycephalus* sp. cf. *B. sulfuratus*”, including the
116 records of *B. hermogenesi* from Cunha et al. (2010) and Oliveira et al. (2011). Bornschein, Pie &

117 Teixeira (2019a) disregarded the possibility of a third unnamed species of flea toad in southern
118 Brazil, but one question remains: the proper identification of *B. sulfuratus* and *B. hermogenesi*.
119 In this sense, the identification criteria used by Bornschein, Pie & Teixeira (2019a) to reevaluate
120 the records of flea toads was not indicated. In addition, there may still be uncertainty in the
121 identification of flea frogs by other authors, as records of *B. hermogenesi* in southern Brazil
122 continue to be published (Santos-Pereira et al. 2016, 2018, Leivas et al. 2018). Given this
123 uncertainty, the aim of this study is to reanalyze the diagnostic morphological traits used to
124 distinguish *B. hermogenesi* and *B. sulfuratus* and redefine its geographical distributions and
125 distributional limits.

126

127 **Materials & Methods**

128 A critical analysis of the species identity of specimens attributable to *Brachycephalus*
129 *hermogenesi*, *B. sulfuratus* or to a similar, potentially undescribed, flea toad from southeastern
130 and southern Brazil was based either on the analysis of their morphology or on their
131 advertisement calls. Our dataset includes the compilation of Bornschein, Pie & Teixeira (2019a),
132 with a few updates. We began by analyzing the actual diagnosis and parameters of the
133 comparisons between species based on the description of *B. sulfuratus* (Condez et al. 2016). We
134 looked for those features in old museum specimens, in our collected specimens, and in sources
135 provided in the literature, particularly photographs of live specimens. Given that our approach
136 uncovered ambiguity in the proposed diagnostic attributes to separate the new species from *B.*
137 *hermogenesi*, we sought new traits that could be useful to distinguish them. New distinctive
138 features found were then erected as diagnostic attributes. In this procedure, we act in accordance
139 of the Recommendation 13A of the International Code of Zoological Nomenclature
140 (<http://www.iczn.org/>). Given that the new distinctive features were listed among described
141 characteristics of the new species, it was not necessary for us to re-describe these characteristics.
142 Rather, we simply demonstrate the existence of the corresponding features in specimens that we
143 identified.

144 We also included unpublished records, vouchered with specimens collected by the
145 authors and deposited in the Museu de História Natural Capão da Imbuia (MHNCI), Curitiba,
146 state of Paraná, Brazil. Collection permits were issued by ICMBIO (10.500, 22470–2/1911426,
147 and 55918–1). Geographical coordinates are based on the WGS84 datum. Elevations for

148 literature records and author's records were obtained from Google Earth, after plotting the
149 location point.

150 We recorded advertisement calls of flea toads using analogical (Sony TCM–5000EV) and
151 digital (Sony PCM–D50 and PCM–M10) devices, with Sennheiser ME 66 microphones. We
152 digitized analogical recordings at 44.1 kHz and 16 bit using Raven Pro 1.4 (Cornell Lab of
153 Ornithology, Ithaca, New York, USA) without any pre-processing. Spectrograms were produced
154 using the program Raven Pro 1.4 on a personal computer with the following settings: Fast
155 Fourier Transform, 256 points, 50% of overlap, and Hann window type. We made adjustments in
156 contrast and brightness with the intention of lightening the images and best highlighting the
157 pulses. We chose not to noise-filter the spectrograms to avoid eliminating sound characters. All
158 calls were deposited in the MHNCI acoustic collection.

159

160 **Results**

161 *Distinction between Brachycephalus sulfuratus and B. hermogenesi*

162 Condez et al. (2016) indicated three morphological characters to distinguish *B. sulfuratus*
163 from the very similar *B. hermogenesi*: 1) “The new species differs from *B. didactylus*, *B.*
164 *hermogenesi*, and *B. pulex* by having (in life) yellow blotches on the ventral surfaces of the
165 throat, chest, arms, and forearms” (Condez et al. 2016: 43, 50); 2) “...the singular inverted v-
166 shaped mark [outlined with white] around the cloacal region in ventral view..., which is not
167 clearly distinguishable in *B. pulex*... and generally rounded and not ornamented in *B. didactylus*...
168 and *B. hermogenesi*...” and usually less distinct in *B. hermogenesi* (Condez et al. 2016: 43, 50);
169 and 3) “the m-shaped mark around the cloacal opening [in dorsal view], which is dark and
170 defined in *B. sulfuratus* sp. nov..., is present but not clearly defined in *B. hermogenesi*” (Condez
171 et al. 2016: 50). However, as we demonstrate below, none of these traits provide an
172 unambiguous identification of *B. sulfuratus* with respect to *B. hermogenesi*. First, some
173 specimens of *B. sulfuratus* that we collected in southern São Paulo, Paraná, and Santa Catarina
174 have revealed that the yellow spots on the ventral surface of this species is still present, on throat,
175 chest, arms, and/or forearms, but not necessarily in all of these body parts. In addition, the
176 amount of yellow is highly variable, being virtually absent in some individuals (Fig. 1).
177 Moreover, three individuals of *B. sulfuratus* collected by us in the state of São Paulo (near the
178 Jurupará dam; Table 1), all collected side by side, have revealed two individuals without any

179 yellow spots on the ventral surface (see one of them in Fig. 11), yet their advertisement calls
180 confirms that they are indeed *B. sulfuratus* (Fig. 2b, c; see below). Second, the inverted v-shaped
181 mark around the cloacal region can be absent in individuals of *B. sulfuratus* (compare Fig. 6A of
182 Condez et al. [2016] and Fig. 1a). Additionally, this characteristic was mischaracterized as a
183 diagnosis from *B. hermogenesi* on the actual original description: “the ventral inverted v-shaped
184 mark in the chest... are shared among the four species [*B. sulfuratus*, *B. hermogenesi*, *B.*
185 *didactylus*, and *B. pulex*]” (Condez et al. 2016: 50). Also, while describing the variation on the
186 type series, the authors stated that “some individuals present the inverted v-shaped around the
187 cloacal region” (Condez et al. 2016: 46). Finally, the “m-shaped mark around the cloacal
188 opening” was also mischaracterized as a diagnostic trait on the actual original description of the
189 species (Condez et al. 2016: 50): “The m-shaped mark around the cloacal opening in dorsal
190 view... are shared among the four species [*B. sulfuratus*, *B. hermogenesi*, *B. didactylus*, and *B.*
191 *pulex*].”

192 Therefore, there are at the present time no morphological traits that could differentiate
193 either live or preserved specimens (Fig. 3) of *B. sulfuratus* from *B. hermogenesi* (we examined
194 preserved specimens from the type series of *B. hermogenesi*, deposited in ZUEC: ZUEC 9715 –
195 holotype, Fig. 3, and ZUEC 9716–25 - paratypes). However, for identification purposes, we
196 considered individuals with yellow spots on their ventral side as *B. sulfuratus*, whereas
197 individuals without yellow spots could be either *B. sulfuratus* or *B. hermogenesi*. However,
198 specimens with yellow spots of *B. sulfuratus* must be observed in life because in the preservative
199 the change in color prevents separate them in relation to specimens of *B. hermogenesi*.

200 In addition to morphological traits, Condez et al. (2016: 43) included in the diagnosis of
201 *B. sulfuratus* the following parameters of the advertisement call: “advertisement call long,
202 composed of a set of 4–7 high-frequency notes (6.2–7.2 kHz) repeated regularly.” The indicated
203 range overlaps with that of *B. hermogenesi*. According to Verdade et al. (2008:545): “The calls
204 [of *B. hermogenesi*] may be simple, constituted by a single note, or complex, composed of
205 groups of two to seven similar notes” with average dominant frequency of 6.8 kHz \pm 0.8 (the
206 frequency amplitude was not provided by Verdade et al. [2008]). In summary, the advertisement
207 call of *B. hermogenesi* is composed of 1–7 notes, whereas that of *B. sulfuratus* is composed of 4–
208 7 notes, with the amplitude of the dominant frequency of *B. hermogenesi* overlapping with the
209 amplitude of dominant frequency of *B. sulfuratus* (\bar{x} = 6.7 \pm 0.3 kHz; Condez et al. [2016: 46]).

210 In the section “Comparisons with other species”, Condez et al. (2016: 50) do not clarify the
211 distinction between these species, by simply stating that “The advertisement call of *B.*
212 *hermogenesi* is the most similar to the new species [*B. sulfuratus*], being quite similar in
213 frequency (dominant frequency = 6.8 kHz), which are the highest recorded for the genus.
214 However, the advertisement call of *B. hermogenesi* can be simple or composed of 2–7 shorter
215 notes with 1–3 pulses (Verdade et al. 2008).”

216 All analyzed advertisement call records (Figs. 2, 4–6) unambiguously allow for the
217 assignment of individuals as *B. sulfuratus* by the number of pulses of single notes, varying
218 between 5–13 in samples shown in the Figs. 2, 4–6 and between 7–11 in the samples of Condez
219 et al. (2016: 46), whereas in *B. hermogenesi* the number of single note pulses is indeed 1–3.
220 Verdade et al. (2008) have not described the number of pulses of notes of *B. hermogenesi*, as
221 stated by Condez et al. (2016:50). However, V. K. Verdade sent us two copies of recordings that
222 she made and used in her study, in which we found two pulses per notes in *B. hermogenesi* from
223 Estação Biológica de Boracéia. Additionally, our recordings of *B. hermogenesi* from Estação
224 Biológica de Boracéia and from its type locality (Corcovado and Núcleo Picinguaba)
225 demonstrated that the number of pulses per note in this species is indeed 1–3.

226 We erect as a diagnosis between *B. sulfuratus* and *B. hermogenesi* the number of pulses
227 of a single note in their advertisement call: 1–3 in *B. hermogenesi* and between 5–13 in *B.*
228 *sulfuratus*. To the best of our knowledge, this is currently the only objective distinction between
229 this species. A more detailed description of call parameters, including specimens across the
230 distribution of each species, might provide additional information to distinguish them (e.g., pace
231 of the advertisement calls, time interval between pulses, and duration of the pulse). We also
232 observed possible population variation in call parameters between recordings of the *B.*
233 *hermogenesi* type localities compared to those located at higher altitudes (e.g., Estação Biológica
234 de Boracéia; see Table 1). This analysis is beyond the scope of this study and will be the focus of
235 a specific study in the future.

236

237 *Reviewed records of Brachycephalus sulfuratus and B. hermogenesi*

238 Based on our review of the 14 occurrence records of “*Brachycephalus* sp. nov. 1” from
239 Pie et al. (2013), we conclude that the vouchered records correspond to *B. sulfuratus* (Table 1;
240 Figs. 5–6). Specimens from Pie et al. (2013) have yellow spots on their ventral side and

241 advertisement calls recorded have notes with several pulses (as above). We treated unvouchered
242 records of Pie et al. (2013) as *Brachycephalus* sp. (Table 1). A specimen from one of those
243 unvouchered locations of Pie et al. (2013), Castelo dos Bugres, was vouchered by Condez et al.
244 (2016). We also determined that the records of unidentified *Brachycephalus* from “Apiaí”,
245 “Caratuval”, “Corvo”, and “Fazenda Thalia” from Firkowski et al. (2016) correspond to *B.*
246 *sulfuratus* (Table 1) based on the inspection of vouchers (specimens had yellow spots on their
247 ventral region - see Fig. 1; sonograms of some of these records are presented in Figs. 4–6). The
248 records of “*Brachycephalus* sp. 1” from Bornschein et al. (2016a) correspond to *B. sulfuratus*
249 (Table 1): all but one of them are the same records as those presented in Pie et al. (2013) and
250 Firkowski et al. (2016) and were re-identified above. The only exception is the record of
251 “*Brachycephalus* sp. 1” from Reserva Particular do Patrimônio Natural Salto Morato,
252 municipality of Guaraqueçaba, Paraná, identified as *B. sulfuratus* (Table 1) based on their call
253 structure, with notes with several pulses (Fig. 5d). With this proposition we reidentified the
254 previous identification of *B. hermogenesi* for Reserva Particular do Patrimônio Natural Salto
255 Morato (Pereira et al. 2010, Santos-Pereira et al. 2011, 2016, 2018, Leivas et al. 2018; Table 1).

256 Some previous studies reporting “*Brachycephalus hermogenesi*” (Giaretta and Sawaya
257 1998, Dixo and Verdade 2006, Verdade et al. 2008, Condez, Sawaya & Dixo 2009, Verdade,
258 Rodrigues & Pavan 2009) from Rio de Janeiro and São Paulo do not provide enough
259 morphological evidence or other details to allow us to correct their original identification (Table
260 1). Therefore, we propose that these identifications should be reverted as *Brachycephalus* sp.
261 One of these records reverted to *Brachycephalus* sp. involves “*B. hermogenesi*” from the
262 municipality of Piedade, state of São Paulo, of Clemente-Carvalho et al. (2011), whose genetic
263 sequence is deposited in GenBank (HQ435724). The corresponding voucher was obtained by T.
264 H. Condez (pers. comm., 2016) in her study on the same location (Condez, Sawaya & Dixo
265 2009).

266 In the description of *B. sulfuratus* (Condez et al. 2016) there are some specimens, from
267 six different localities, cited as “*B. hermogenesi*” in the appendix. These specimens were used by
268 Condez et al. (2016) only for “morphological analyses”. There is the possibility that all of these
269 records are based on preserved material, preventing Condez et al. (2016) to analyze color
270 patterns in life and to unambiguously distinguish them from *B. sulfuratus*, as our statements

271 above. Therefore, we also propose that those identifications should be considered as
272 *Brachycephalus* sp. (Table 1; see also Bornschein et al. 2016a).

273 There is a particular specimen (ZUEC 16602), discussed above and also examined by us,
274 collected in the state of Paraná, that was first identified as “*Brachycephalus aff. hermogenesi*”
275 (Cunha et al. (2010), later as “*B. hermogenesi*” (Oliveira et al. (2011), “*Brachycephalus* sp. nov.
276 1” (Pie et al. 2013), “*Brachycephalus* sp. 1” (Bornschein et al. 2016a), and, finally as “*B.*
277 *sulfuratus*” (Condez et al. 2016). We also believe that this specimen may not have been properly
278 analyzed with respect to coloration in life, preventing the precise identification as a specimen in
279 preservative (see above). Therefore, we also propose that this identification should be reverted to
280 *Brachycephalus* sp. (Table 1).

281

282 Discussion

283 Based on our analyses of the characters used in the diagnosis of *B. sulfuratus*, we found
284 that they are variable and overlap with those found in *B. hermogenesi*. Moreover, the
285 examination of specimens deposited in the collections MHNCI and ZUEC support this claim.
286 Differences in number of pulses per note is proposed here as the only available source of
287 evidence supporting the distinction of *B. sulfuratus* and *B. hermogenesi*. We emphasize that the
288 diagnosis between these species based only on the number of pulses cannot be interpreted as a
289 weak diagnosis. Even in the field its advertisement calls are very distinct and easily
290 distinguishable. The advertisement calls of *B. sulfuratus* sounds like a “trííííí, trííííí, trííííí,
291 trííííí, trííííí”, whereas those of *B. hermogenesi* sound like a “tíc, tíc, tíc, tíc-tíc, tíc-tíc-tíc”.
292 These transliterations represent notes (each note separated by comma) with distinct duration
293 related to high number of pulses per note in the first species in opposition of reduced number of
294 pulses in the second. The advertisement calls of *B. hermogenesi* have the same pattern of that of
295 species from the *B. pernix* group (Bornschein et al. 2018, 2019b, Pie et al. 2018a, Monteiro et al.
296 2018a, 2018b), which includes most species of southern Brazil whereas the call of *B. sulfuratus*
297 resembles the one of *B. vertebralis* (MRB, unpublished data), for example, from the *B. ephippium*
298 group, which includes most species from the state of São Paulo to the north. To the best of our
299 knowledge, this is the first case in which the diagnosis between species of *Brachycephalus* is
300 made solely by features of the advertisement call.

301 Our results expand the knowledge on the number of single-note pulses in *B. sulfuratus*,
302 previously described as having between 7–11 pulses (Condez et al. 2016). We underscore a
303 necessity to re-describe the calls of *B. hermogenesi*, particularly given that there is not enough
304 information on how some of the parameters were measured by Verdade et al. (2008).
305 Nevertheless, the objective with our call analysis was to include sonograms showing the
306 structure of the notes (number of pulses) as a “snapshot” to allow for the identification of the
307 species that emitted the calls. A comprehensive description of our recordings would require
308 including the entire sample size of individuals from the same localities, as well as to discard any
309 low-quality calls, even if they were the only available vouchers of certain localities,
310 mischaracterizing the purpose for which calls are included here.

311 We show that there is now confirmed occurrence of *B. hermogenesi* in southern Brazil
312 and that *B. sulfuratus* occurs far north to the east of São Paulo city, only 67 km in straight line
313 from the southernmost site of record of *B. hermogenesi* (Estação Biológica de Boracéia; Fig. 7;
314 Table 1). Although we reversed several records of *B. sulfuratus* and *B. hermogenesi* to
315 *Brachycephalus* sp. (Table 1), this now means that a third species may be involved. The
316 unidentified records in Table 1 represent one or the other of these two species. In fact, it is likely
317 that in southern Brazil only the flea toad *B. sulfuratus* will occur. Only from the south of São
318 Paulo to the north until the city of São Paulo is the distribution of flea toads little known. In
319 southern Brazil, our group has been working with two genera of anurans (*Brachycephalus* and
320 *Melanophryniscus*) since 2009, focusing on their distribution, ecology and conservation (e.g., Pie
321 et al. 2013, Bornschein et al. 2015, 2016a, Bornschein, Pie & Teixeira 2019a), and we do not
322 leave any calls heard like those of the group *B. pernix* without collection and we never found *B.*
323 *hermogenesi*.

324 In addition, we have also absence of records of *B. sulfuratus* in northern Santa Catarina in
325 some well sampled localities. For example, we have made no records for *B. sulfuratus* in Morro
326 Boa Vista (26°30'58"S, 49°03'14"W), on the border between the municipalities of Jaraguá do
327 Sul and Massaranduba, where we described *B. albolineatus* (Bornschein et al. 2016b), Morro do
328 Baú (26°47'58"S, 48°55'47"W), municipality of Ilhota, and Morro Braço da Onça (26°44'58"S,
329 48°55'41"W), municipality of Luiz Alves, where we report *B. fuscolineatus* (Ribeiro et al. 2015,
330 Bornschein, Teixeira & Ribeiro 2019c), Morro do Cachorro (26°46'42"S, 49°01'57"W), on the
331 border between the municipalities of Blumenau, Gaspar, and Luiz Alves, where we described *B.*

332 *boticario* (Ribeiro et al. 2015), and Morro Santo Anjo (26°37'41"S, 48°55'50"W), municipality
333 of Massaranduba, where we described *B. mirissimus* (Pie et al. 2018a). There is a possibility that
334 around Morro do Garrafão (Table 1) is situated the southern limit of the geographic distribution
335 of *B. sulfuratus*.

336 As we demonstrate, there is no confirmed overlap in the distribution of *B. hermogenesi*
337 and *B. sulfuratus* and their replacements occurs in southeastern of São Paulo city, without
338 apparent barriers. There are other examples of discontinuity of the geographical distribution
339 between congeneric species throughout the Atlantic Forest from southeastern to southern Brazil
340 in southeastern São Paulo city, as in the montane bird *Scytalopus speluncae* (taxonomy *sensu*
341 Maurício et al. [2010]). Maurício (2005) stated that populations of *S. speluncae* from the
342 southeastern of the city of São Paulo to the south of the species distribution represent a distinct
343 species yet to be named, and he treated it as “Southern *Scytalopus speluncae*” (this scenario of
344 southern population of this bird as a new species was supported by the result of other studies
345 [Bornschein et al. 2007, Mata et al. 2009, Maurício et al. 2014, Pulido-Santacruz et al. 2016]). In
346 the region around the southeastern of São Paulo city, cases of hybridization of subspecies or
347 lineages of at least four species of birds have been reported (Pinto 1941, Silva and Stotz 1992,
348 Cabanne, Santos & Miyaki 2007, D’Horta et al. 2011; see also Dantas et al. [2015]). In the state
349 of São Paulo there is another discontinuity which is associated with intraspecific differentiation
350 or even sister species of frogs (Fitzpatrick et al. 2009, Thomé et al. 2010, Amaro et al. 2012) and
351 snakes (Grazziotin et al. 2006).

352 The correspondence between the distribution of the congeneric species in question with
353 the limits of the Serra do Mar is intriguing, given that during the last 20 million years there was
354 no obvious uplift in the region (Gontijo-Pascutti et al. 2012). This time scale is considerably
355 older than the inferred cladogenesis events and therefore geological processes could not have
356 been the primary cause of their divergence, given that *Brachycephalus* toads and *Scytalopus*
357 birds of São Paulo, Paraná, and Santa Catarina originated less than 2-5 million years ago (Pie et
358 al. [2018b] and Pulido-Santacruz et al. [2016], respectively). Likewise, recent neotectonic
359 activities (Late Pleistocene-Holocene) are restricted to the faults and stress regimes (Hasui 1990,
360 Saadi, 1993, Riccomini and Assumpção 1999) and, therefore, also could not have generated the
361 diversification pattern of widely distributed terrestrial species. It is important to note that Thomé
362 et al. (2010), studying the toad *Rhinella crucifer* from the eastern portion of Brazil, associate one

363 genetic break found in eastern São Paulo to neotectonic barriers, specifically the Cubatão shear
364 zone and the Guapiara lineament. However, these are ancient geotectonic activities, from
365 Proterozoic to Cambrian (with Phanerozoic reactivation) and Mesozoic, respectively (Ferreira et
366 al. 1981, Sadowski 1990, Almeida and Carneiro, 1998; see also Riccomini and Assumpção
367 1999). In addition, studies have proposed speciation by vicariance caused by relatively recent
368 events, such as river barriers (e.g., Amaral et al. 2013), sea level variation (Grazziotin et al. 2006,
369 Fitzpatrick et al. 2009), and forest refugia (e.g., Fitzpatrick et al. 2009, Thomé et al. 2010,
370 D’Horta et al. 2011, Amaral et al. 2013). The largest river around the disruption of the
371 geographical distribution of *B. sulfuratus* and *B. hermogenesi* is the Rio Ribeira do Iguape,
372 which intersects the Serra do Mar between São Paulo and Paraná States by continued erosive
373 retreat (Almeida and Carneiro 1998) or, alternatively, originated in tectonic depression
374 associated with asymmetric graben of the Sete Barras or Ribeira de Iguape (Melo et al. 1989,
375 Gontijo-Pascutti et al. 2012), which did not lead to isolation, given that *B. sulfuratus* occurs on
376 both of its banks. It is plausible that the origin of *B. sulfuratus* and *B. hermogenesi*, as well as the
377 other examples mentioned above, might have resulted from climatic variations that promoted
378 vicariance by forest cover disruption followed by recovery of forest coverage, presumably
379 leading to secondary contact.

380 The region in the state of São Paulo, around the southeastern São Paulo city, should be
381 further investigated. Records of flea toads in this region could be obtained as background sound
382 in recordings of birds (e.g., those deposited in databases such as www.xeno-canto.org and
383 www.wikiaves.com.br). Verdade et al. (2008) made a similar suggestion: to search for records of
384 *B. hermogenesi* in the background of recordings of birds from the Estação Biológica de Boracéia,
385 in the case one wants to seek previous records of this flea toad in this highly sampled locality. As
386 examples, calls of *B. sulfuratus* in Parque Estadual Intervales, municipality of Iporanga, state of
387 São Paulo (Table 1), can be heard in recordings of the birds *Merulaxis ater* (XC80463 and
388 XC18179) and *Eleoscytalopus indigoticus* (XC75544; available in www.xeno-canto.org).

389 We underscore the importance of continuous scrutiny of the distribution and
390 advertisement call analysis of *B. sulfuratus* and *B. hermogenesi*. Call parameters were poorly
391 described for *B. hermogenesi* and a better knowledge of the geographical limits between these
392 species can elucidate distribution patterns and potentially detect cases of sympatry. To date, there
393 are no confirmed cases of sympatry between species of *Brachycephalus* in the same group, only

394 between species from distinct groups (*B. pernix* and *B. didactylus* groups and *B. ephippium* and
395 *B. didactylus* groups; Bornschein et al. [2016a], Bornschein, Pie & Teixeira [2019a]). The
396 possibility of sympatry between *B. hermogenesi* and *B. sulfuratus* in eastern São Paulo is high,
397 but the distinctions of their advertisement calls could provide pre-zygotic isolation. Although
398 some species in the *B. ephippium* group are additively insensitive to the own advertisement call
399 (Goutte et al. 2017), which would suggest loss of active selection pressure and variation
400 maintained by inertia, it must be considered that this scenario may not apply to the other groups
401 (Monteiro et al. 2018a) and, also, that the species may actively perceive call emissions through
402 vibrations in other body receptors.

403

404 **Conclusions**

405 *Brachycephalus sulfuratus* differs from *B. hermogenesi* only by its advertisement calls;
406 other morphological characteristics suggested for its differentiation vary individually and are
407 shared with *B. hermogenesi*. The advertisement calls of these species differ greatly, even in the
408 field, with that of *B. sulfuratus* consisting of many pulses per note and that of *B. hermogenesi* by
409 up to three pulses per note. The advertisement calls of *B. sulfuratus* resemble those of species of
410 the *B. ephippium* species group, whereas the calls of *B. hermogenesi* resemble those of the *B.*
411 *pernix* species group. These similarities are intriguing, given that *B. sulfuratus* and *B.*
412 *hermogenesi* are part of the *B. didactylus* group. Understanding the evolution of these
413 advertisement calls should require a more in depth investigation.

414 All previous records of *B. hermogenesi* from southern Brazil should instead be
415 considered as *B. sulfuratus*, in a possibly cascading error resulting from the inadequate revision
416 of the records prior to the description of *B. sulfuratus* (Condez et al. 2016). A large region in the
417 south of the state of São Paulo needs to be further investigated to confirm the presence of *B.*
418 *hermogenesi*; the previous records were reverted to *Brachycephalus* sp. *Brachycephalus*
419 *sulfuratus* is distributed much further north than previously thought and it is possible that
420 sympatry with *B. hermogenesi* may occur in the southwest of the city of São Paulo. This region
421 in the southwest of São Paulo is particularly interesting because many species of different taxa
422 have their range limits there. The biogeographic explanation of this pattern seems to be limited to
423 the past distribution of forest patches, which could have been previously isolated and are now
424 distributed continuously, allowing possible secondary contact of species.

425

426 Acknowledgements

427 Diego Baldo, Stefano Spiteri, and André Confetti provided valuable assistance during field work.

428 Vanessa K. Verdade provided two samples of the advertisement call of *Brachycephalus*

429 *hermogenesi*. Milene Fornari provided bibliography for the discussion on biogeography. MRP

430 was supported through a grant from CNPq/MCT (571334/2008–3).

 4 Campinas, Campinas, state of São Paulo, Brazil.

Species	Locality and state	Geographical coordinates and altitude	Previous identification	Voucher	Our analysis of the record
<i>B. hermogenesi</i>	Corcovado, municipality of Ubatuba, São Paulo	23°28'20"S, 45°11'41"W; 30–250 m a.s.l.	Giaretta and Sawaya (1998; as <i>B. hermogenesi</i>), Verdade et al. (2008; as <i>B. hermogenesi</i>), Pie et al. (2013; as <i>B. hermogenesi</i>), Bornschein et al. (2016a; as <i>B. hermogenesi</i>), Pie et al. (2018a; as <i>B. hermogenesi</i> collected at Picinguaba [= Corcovado]), Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Specimens (including paratypes) and recordings	Specimens (ZUEC 9722–4, MHNCI 10823–25) and calls examined.
<i>B. hermogenesi</i>	Estação Biológica de Boracéia, municipality of Salesópolis, São Paulo	23°39'10"S, 45°53'05"W; 825–900 m a.s.l.	Pimenta et al. (2007; as <i>B. hermogenesi</i>), Verdade et al. (2008; as <i>B. hermogenesi</i>), Pie et al. (2013; as <i>B. hermogenesi</i>), Bornschein et al. (2016a; as <i>B. hermogenesi</i>), Condez et al. (2016; as <i>B. hermogenesi</i>)	Specimens and recordings	Specimens (MHNCI, one uncatalogued specimen) and calls examined (including recordings sent by V. K. Verdade; Fig. 2a).
<i>B. hermogenesi</i>	Fazenda Capricórnio, municipality of Ubatuba, São Paulo	23°23'27"S, 45°04'26"W; 60 m a.s.l.	Giaretta and Sawaya (1998;), Verdade et al. (2008; as <i>B. hermogenesi</i>), Pie et al. (2013; as <i>B. hermogenesi</i>), Bornschein et al. (2016a; as <i>B. hermogenesi</i>), Condez et al. (2016; as <i>B. hermogenesi</i>)	Specimens (paratypes)	Specimen examined (ZUEC 9725).
<i>B. hermogenesi</i>	Morro Cuscuzeiro, on the border of municipalities of	23°17'50"S, 44°47'21"W; 730–1,090 a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Recordings	Calls examined.

Species	Locality and state	Geographical coordinates and altitude	Previous identification	Voucher	Our analysis of the record
<i>B. hermogenesi</i>	Paraty, Rio de Janeiro, and Ubatuba, São Paulo Morro do Corcovado, Parque Estadual da Serra do Mar, municipality of Ubatuba, São Paulo	23°27'06"S, 45°12'03"W; 250–1,060 m a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Recordings	Calls examined.
<i>B. hermogenesi</i>	Municipality of Paraibuna, São Paulo	c. 23°23'34"S, 45°39'42"W; altitude?	Condez et al. 2016 (as <i>B. hermogenesi</i>)	Specimen	---
<i>B. hermogenesi</i>	Núcleo Cunha, Parque Estadual da Serra do Mar, municipality of Cunha, São Paulo	23°15'48"S, 45°02'39"W; 1,045–1,140 m a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Specimen and recordings	Specimen (MHNCI, one uncatalogued specimen) and recordings examined.
<i>B. hermogenesi</i>	Núcleo Picinguaba, Parque Estadual da Serra do Mar, municipality of Ubatuba, São Paulo	23°22'21"S, 44°49'53"W; 0–700 m a.s.l.	Giaretta and Sawaya (1998), Pimenta et al. (2007; as <i>B. hermogenesi</i>), Verdade et al. (2008; as <i>B. hermogenesi</i>), Clemente-Carvalho et al. (2009; as <i>B. hermogenesi</i>), Pie et al. (2013; as <i>B. hermogenesi</i>), Bornschein et al. (2016a; as <i>B. hermogenesi</i>), Condez et al. (2016; as <i>B. hermogenesi</i>), Pie et al. (2018a; as <i>B. hermogenesi</i>)	Specimens (holotype and paratypes) and recordings	Specimens (ZUEC 9715–21; Fig. 3d) and calls examined.
<i>B. hermogenesi</i>	Sertão da Cutia, municipality of Ubatuba, So Paulo	not located	Condez et al. (2016; as <i>B. hermogenesi</i>)	Specimen	---
<i>B. hermogenesi</i>	Trilha do Corisco, municipality of Paraty,	23°16'38"S, 44°46'39"W; 350–725 m a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Recordings	Calls examined.

Species	Locality and state	Geographical coordinates and altitude	Previous identification	Voucher	Our analysis of the record
<i>B. hermogenesi</i>	Rio de Janeiro Trilha do Ipiranga 50 m from the Rio Ipiranga, Núcleo Santa Virgínia, Parque Estadual da Serra do Mar, municipality of São Luiz do Paraitinga, São Paulo	23°20'41"S, 45°08'21"W; 920–940 m a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. hermogenesi</i>)	Recordings	Calls examined.
<i>B. sulfuratus</i>	Bairro Rio Vermelho, municipality of Barra do Turvo, São Paulo	24°59'25"S, 48°32'26"W; 790 m a.s.l.	---	Specimen	Specimen examined (MHNCI 11584).
<i>B. sulfuratus</i>	Base of the Serra Água Limpa, municipality of Apiaí, São Paulo	24°28'52"S, 48°47'12"W; 920 m a.s.l.	Bornschein et al. (2016a; as <i>Brachycephalus</i> sp. 1), Bornschein et al. (2016b; as <i>B. sulfuratus</i>), Firkowski et al. (2016; without species identification), Ribeiro et al. (2017; as <i>B. sulfuratus</i>), Pie et al. (2018a; as <i>B. sulfuratus</i>)	Specimen and recordings	Specimen (MHNCI 11583; Fig. 1f) and calls examined (MHNCI 129; Fig. 4d).
<i>B. sulfuratus</i>	Biquinha, municipality of Juquiá, São Paulo	24°17'43"S, 47°36'26"W; 40 m a.s.l.	Bornschein, Pie & Teixeira, 2019a (as <i>B. sulfuratus</i>)	Recordings	Calls examined (MHNCI 128; Fig. 4c).
<i>B. sulfuratus</i>	Braço do Norte, municipality of Itapoá, Santa Catarina	26°07'29"S, 48°43'48"W; 240 m a.s.l.	Monteiro et al. (2018a; as <i>B. sulfuratus</i>)	Specimen and genetic	---
<i>B. sulfuratus</i>	Caratuval, near the Parque Estadual das Lauráceas, municipality of Adrianópolis, Paraná	24°51'17"S, 48°43'43"W; 900 m a.s.l.	Pie et al. (2013; as <i>Brachycephalus</i> sp. nov. 1), Bornschein et al. (2016a; as <i>Brachycephalus</i> sp. 1), Bornschein et al. (2016b; as <i>B. sulfuratus</i>), Firkowski et al.	Specimen and recordings	Specimen (MHNCI 11571; Fig. 1b) and calls examined (MHNCI 131; Fig. 5b).

Species	Locality and state	Geographical coordinates and altitude	Previous identification	Voucher	Our analysis of the record
<i>B. sulfuratus</i>	Caratuval, Parque Estadual das Lauráceas, municipality of Adrianópolis, Paraná	24°51'14"S, 48°42'01"W; 890 m a.s.l.	(2016; without species identification), Ribeiro et al. (2017; as <i>B. sulfuratus</i>), Pie et al. (2018a; as <i>B. sulfuratus</i>) Pie et al. (2013; as <i>Brachycephalus</i> sp. nov. 1), Bornschein et al. (2016a; as <i>Brachycephalus</i> sp. 1)	Recordings	Calls examined (MHNCI 132; Fig. 5c).
<i>B. sulfuratus</i>	Castelo dos Bugres, municipality of Joinville, Paraná	26°13'47"S, 49°03'20"W; 790–860 m a.s.l.	Pie et al. (2013; as <i>Brachycephalus</i> sp. nov. 1), Bornschein et al. (2016a; as <i>Brachycephalus</i> sp. 1), Condez et al. (2016; as <i>B. sulfuratus</i>), Monteiro et al. (2018a; as <i>B. sulfuratus</i>)	Specimen, recordings, and genetic	Calls examined.
<i>B. sulfuratus</i>	Centro de Estudos e Pesquisas Ambientais da Univille, Vila da Glória, Distrito do Saí, municipality of São Francisco do Sul, Santa Catarina	26°13'39"S, 48°41'31"W; 125 m a.s.l.	Condez et al. (2016; as <i>B. sulfuratus</i>)	Specimen, recordings, and genetics	---

Figure 1

Ventral view of life specimens of *Brachycephalus sulfuratus*

Figure 1. Ventral view of life specimens of *Brachycephalus sulfuratus* initially deposited in the Coleção Herpetológica do Departamento de Zoologia (DZUP), Universidade Federal do Paraná, Curitiba, Paraná, Brazil, and transferred to Museu de História Natural Capão da Imbuia (MHNCI), Curitiba, Paraná, Brazil. a) MHNCI 11575 (ex-DZUP 153) (Corvo); b) MHNCI 11571 (ex-DZUP 139)(Caratuval, near the Parque Estadual das Lauráceas); c) MHNCI 11582 (ex-DZUP 224) (Fazenda Thalia); d) MHNCI 11579 (ex-DZUP 221) (Fazenda Thalia); e) MHNCI 11573 (ex-DZUP 151) (Corvo); f) MHNCI 11583 (ex-DZUP 362) (base of the Serra Água Limpa); g) MHNCI 11580 (ex-DZUP 222) (Fazenda Thalia); h) MHNCI 11581 (ex-DZUP 223) (Fazenda Thalia); i) MHNCI 10788 (ex-DZUP 154) (Corvo); j) MHNCI 10790 (near the Jurupará dam); k) MHNCI 10826 (Morro do Garrafão); l) MHNCI 10792 (near the Jurupará dam). Notice the variable of yellow spots, absent in specimen “l”, as well as the absence of the dark-brown inverted v-shaped mark on the cloacal region of specimen “a”. Compare sonograms from specimens “j” and “l” in Fig. 2b, c. The presence of yellow spots and v-shaped mark was proposed as diagnostic characteristics to distinguish *B. sulfuratus* from *B. hermogenesi*, but they are variable intraspecifically. For details on geographical localities, see Table 1. Photo credit: Luiz Fernando Ribeiro.

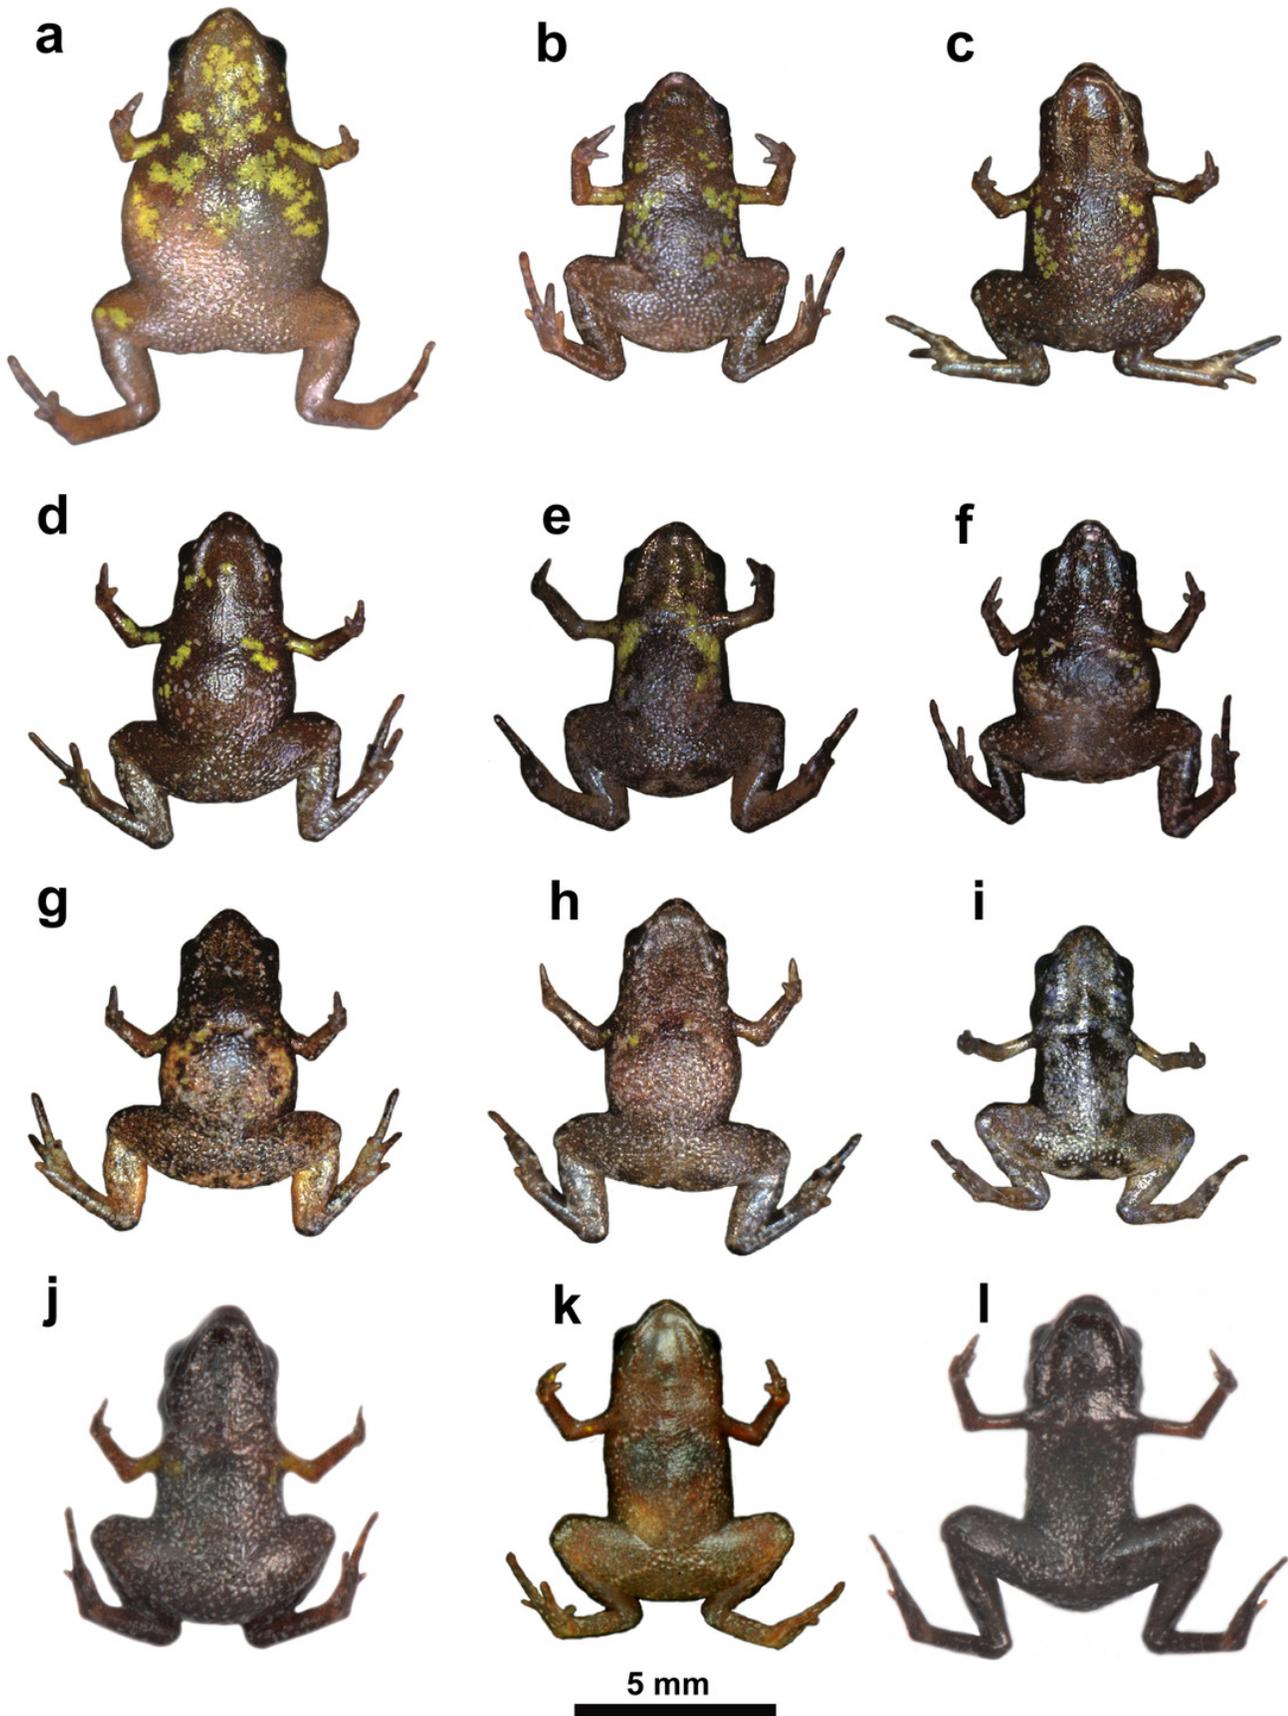

Figure 2

Spectrograms (above) and oscillograms (below) of a single note of the advertisement call of *Brachycephalus hermogenesi* and *B. sulfuratus*

Figure 2. Spectrograms (above) and oscillograms (below) of a single note of the advertisement call of *Brachycephalus hermogenesi* and *B. sulfuratus*. Calls of *B. sulfuratus* were obtained by the authors for this study and are shown from north to the south. Each figure was produced in Raven Pro 1.4, with the scales of both axes edited in CorelDRAW. a) *B. hermogenesi*: Estação Biológica de Boracéia (recorded by V. K. Verdade, without details). b) *B. sulfuratus*: near the Jurupará dam (MHNCI 123; specimen MHNCI 10790). c) *B. sulfuratus*: near the Jurupará dam (MHNCI 124; specimen MHNCI 10791 or MHNCI 10792). d) *B. sulfuratus*: near the Jurupará dam (MHNCI 125; specimen not collected). Notice two pulses for *B. hermogenesi* and several for *B. sulfuratus*. For details on geographical localities, see Table 1.

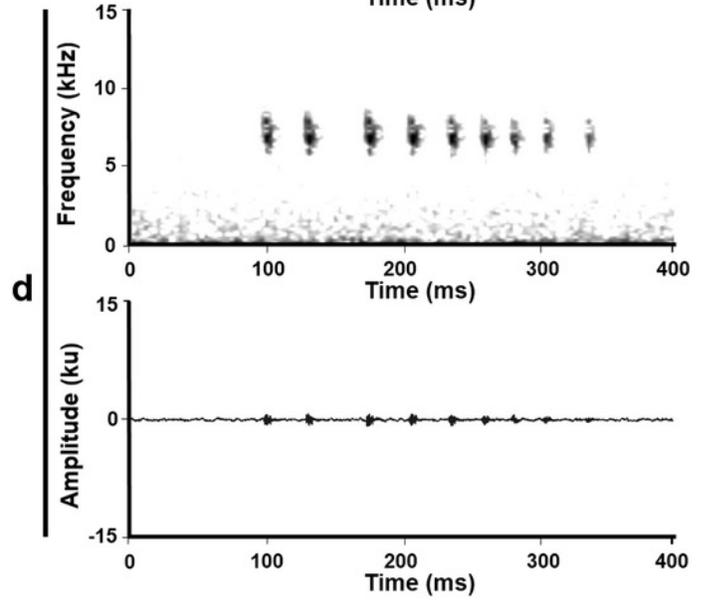

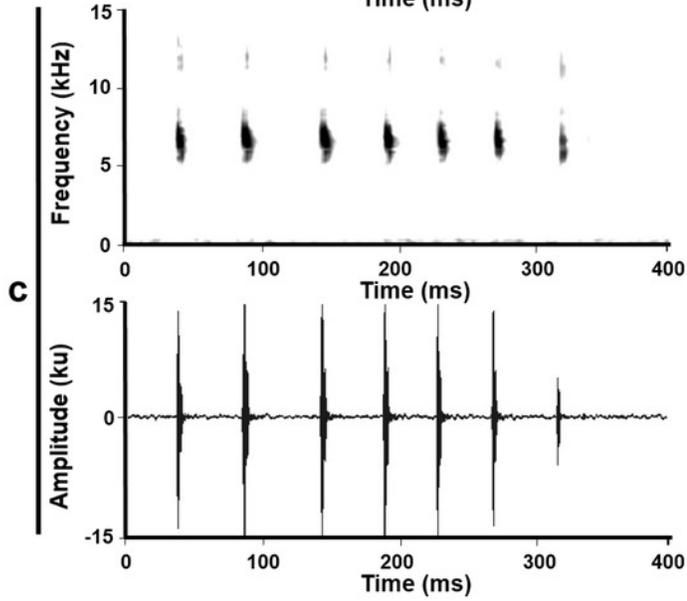

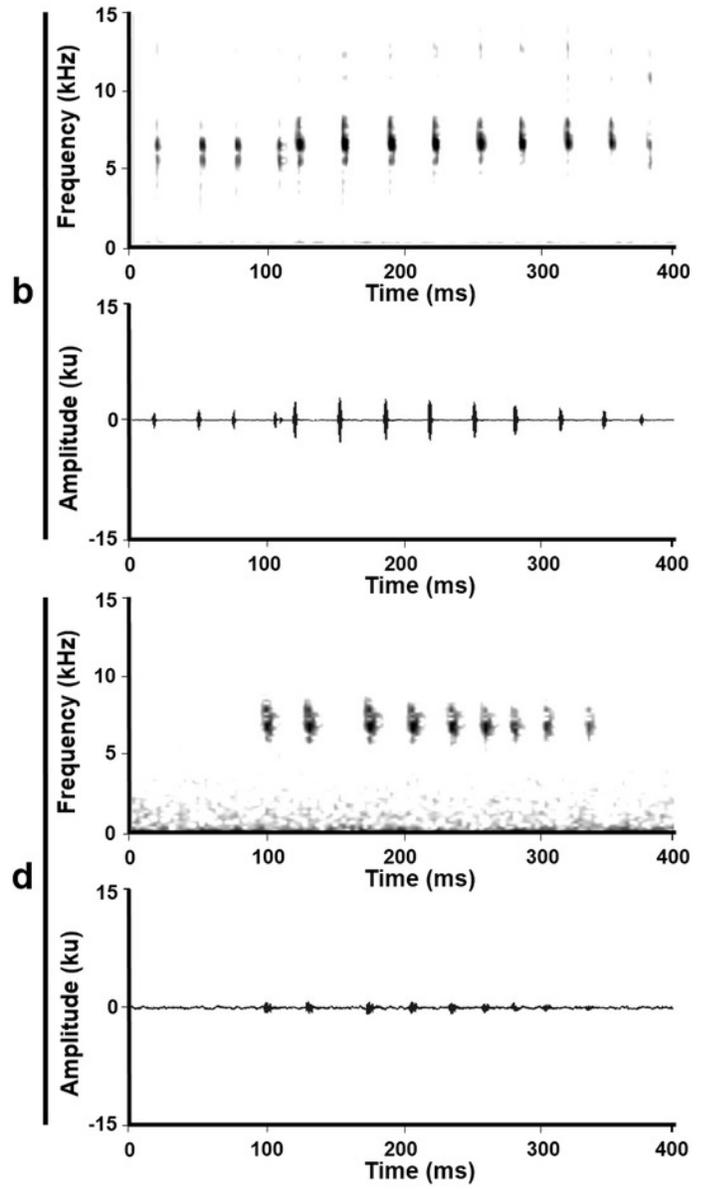

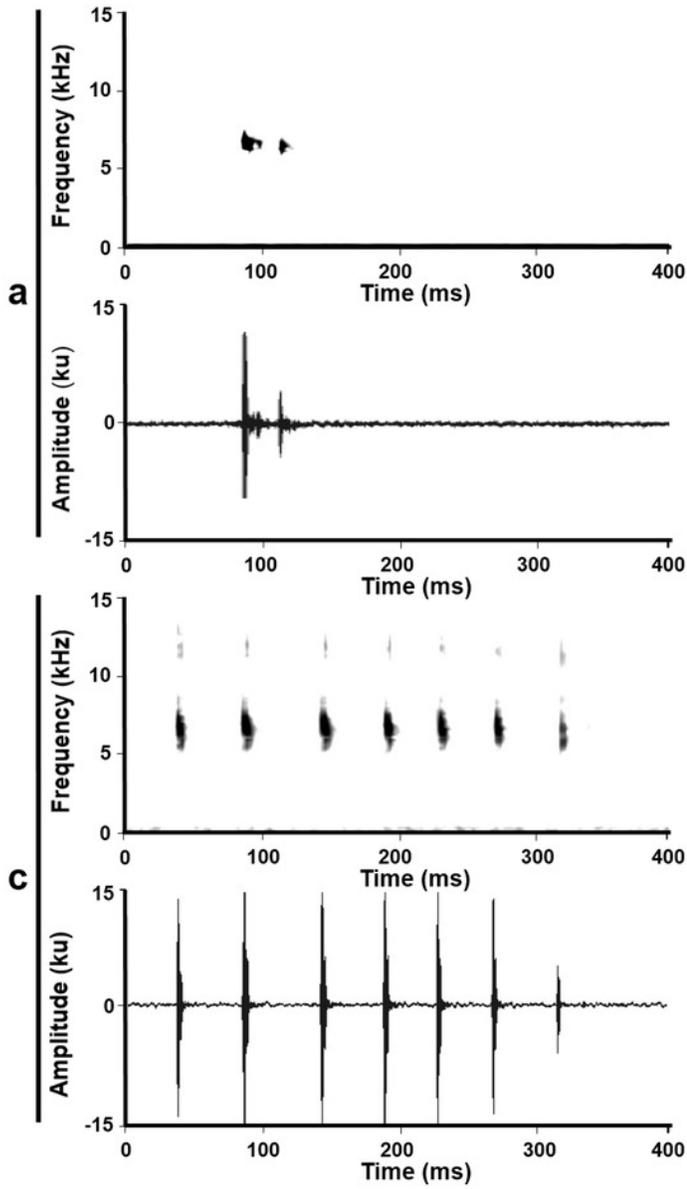

Figure 3

Ventral view of specimens of *Brachycephalus sulfuratus* (a-c) and *B. hermogenesi* (d) in preservative

Figure 3. Ventral view of specimens of *Brachycephalus sulfuratus* (a-c) and *B. hermogenesi* (d) in preservative, deposited in the Coleção Herpetológica do Museu de História Natural Capão da Imbuia (MHNCI), Curitiba, Paraná, Brazil, and Museu de História Natural (ZUEC), Universidade Estadual de Campinas, Campinas, São Paulo, Brazil: a) MHNCI 9800 (Salto do Inferno); b) MHNCI 10302 (Mananciais da Serra); c) MHNCI 10303 (Corvo; ex Coleção Herpetológica do Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brazil, DZUP 589); and d) ZUEC 9715 (holotype of *B. hermogenesi*). Notice the variation in ventral coloration. For details on geographical localities, see Table 1. Photo credit: Luiz Fernando Ribeiro.

Figure 5. Spectrograms (above) and oscillograms (below) of a single note of the advertisement call of *Brachycephalus sulfuratus*. Calls were obtained by the authors for this study and are shown from north to the south. Each figure was produced in Raven Pro 1.4, with the scales of both axes edited in CorelDRAW. a) Serra do Guaraú (MHNCI 130; specimen not collected). b) Caratuval, near the Parque Estadual das Lauráceas (MHNCI 131; specimen MHNCI 11571). c) Caratuval, Parque Estadual das Lauráceas (MHNCI 132; specimen not collected). d) Reserva Particular do Patrimônio Natural Salto Morato (MHNCI 133; specimen not collected). For details on geographical localities, see Table 1.

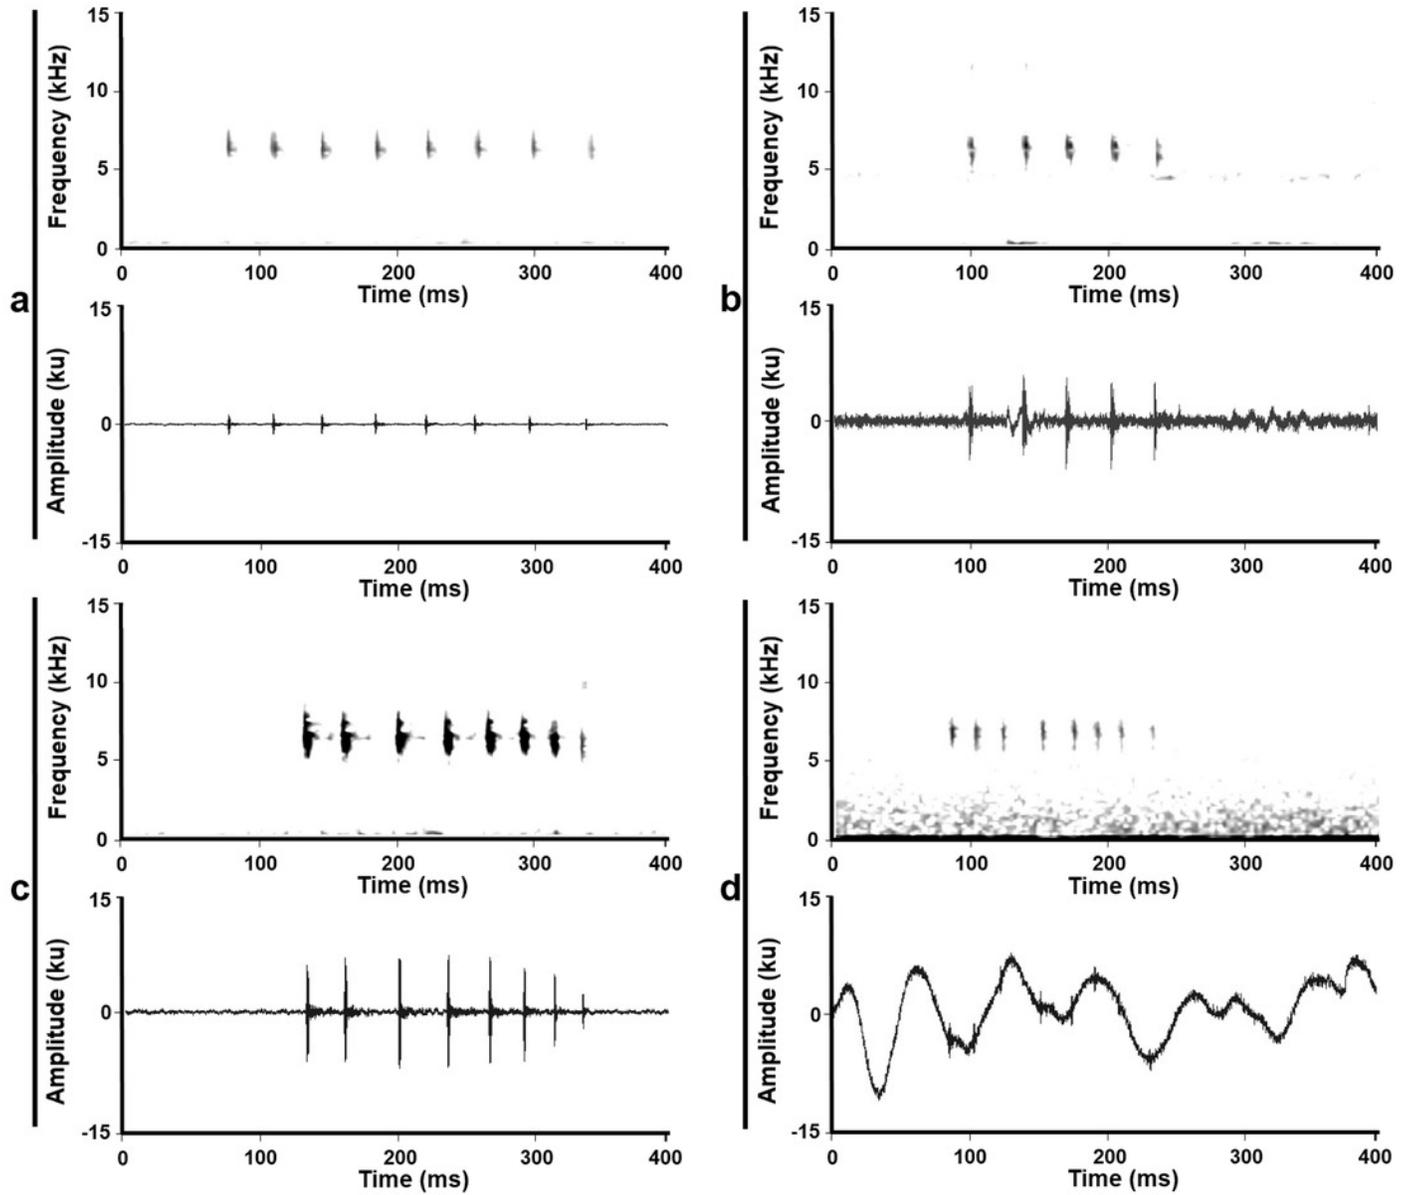

Figure 6

Spectrograms (above) and oscillograms (below) of a single note of the advertisement call of *Brachycephalus sulfuratus*.

Figure 6. Spectrograms (above) and oscillograms (below) of a single note of the advertisement call of *Brachycephalus sulfuratus*. Call were obtained by the authors for this study and are shown from north to the south. Each figure was produced in Raven Pro 1.4, with the scales of both axes edited in CorelDRAW. a) Fazenda Thalia (MHNCI 134; specimen not collected). b) Truticultura (MHNCI 135; specimen not collected). c) Morro Garuva (MHNCI 136; specimen not collected). d) Morro do Garrafão (MHNCI 137; specimen not collected). For details on geographical localities, see Table 1.

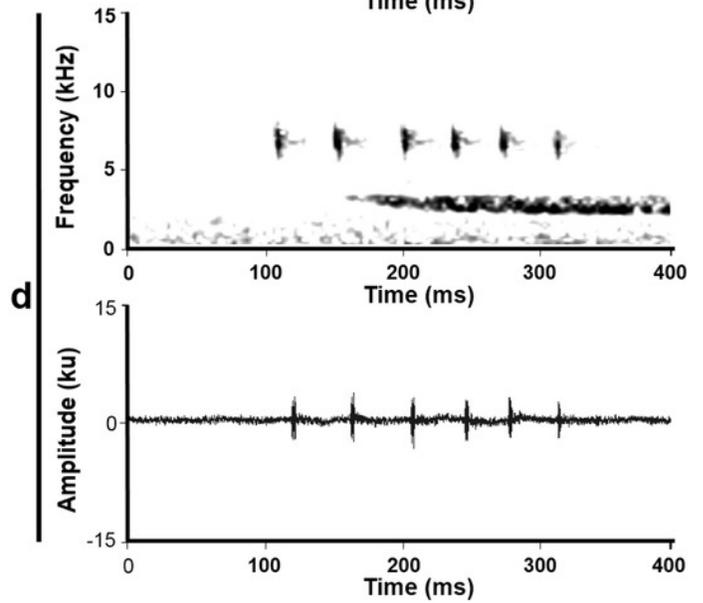

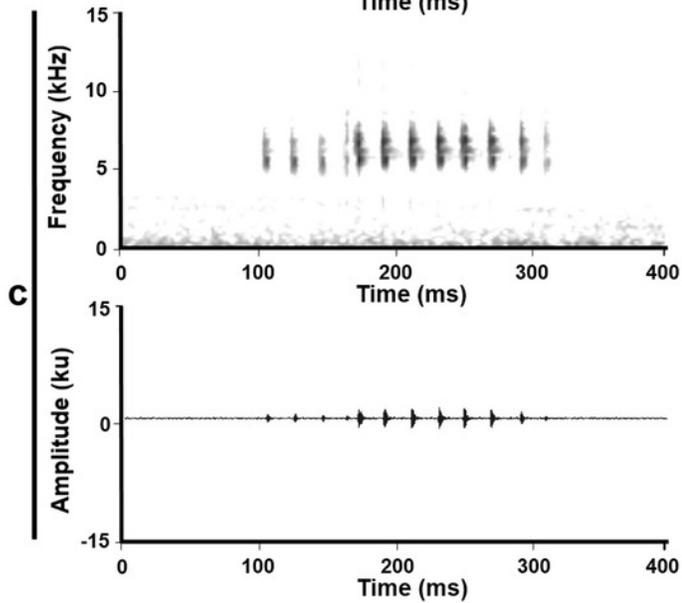

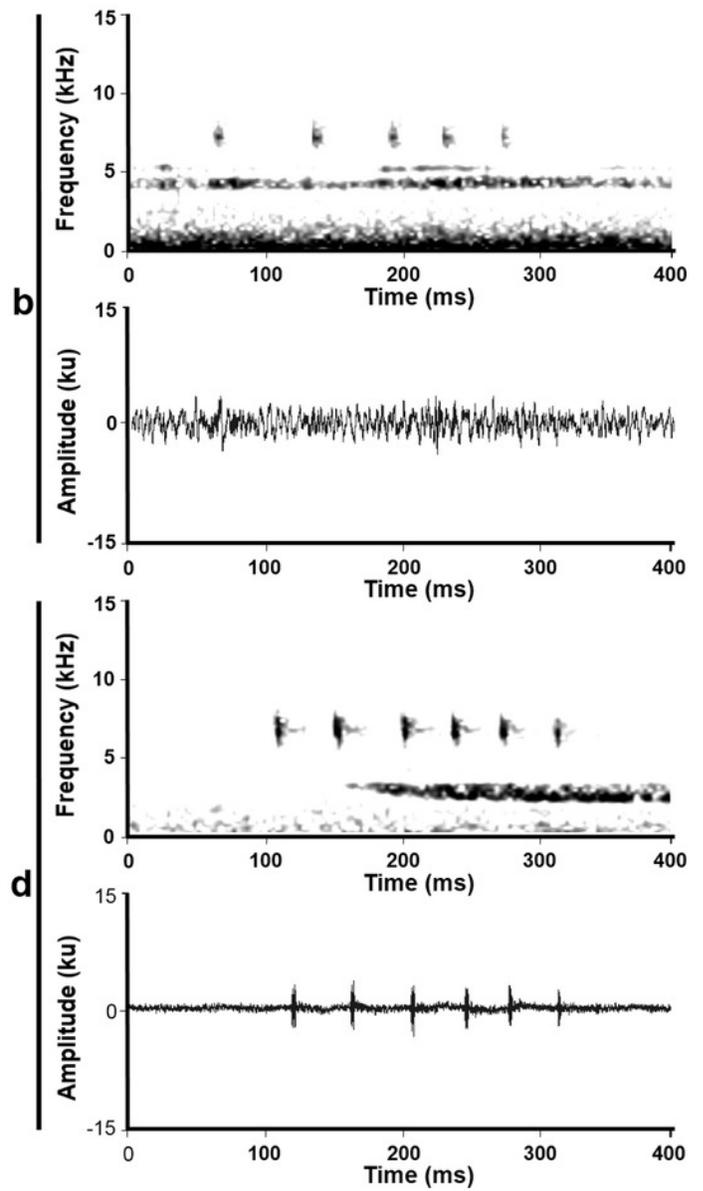

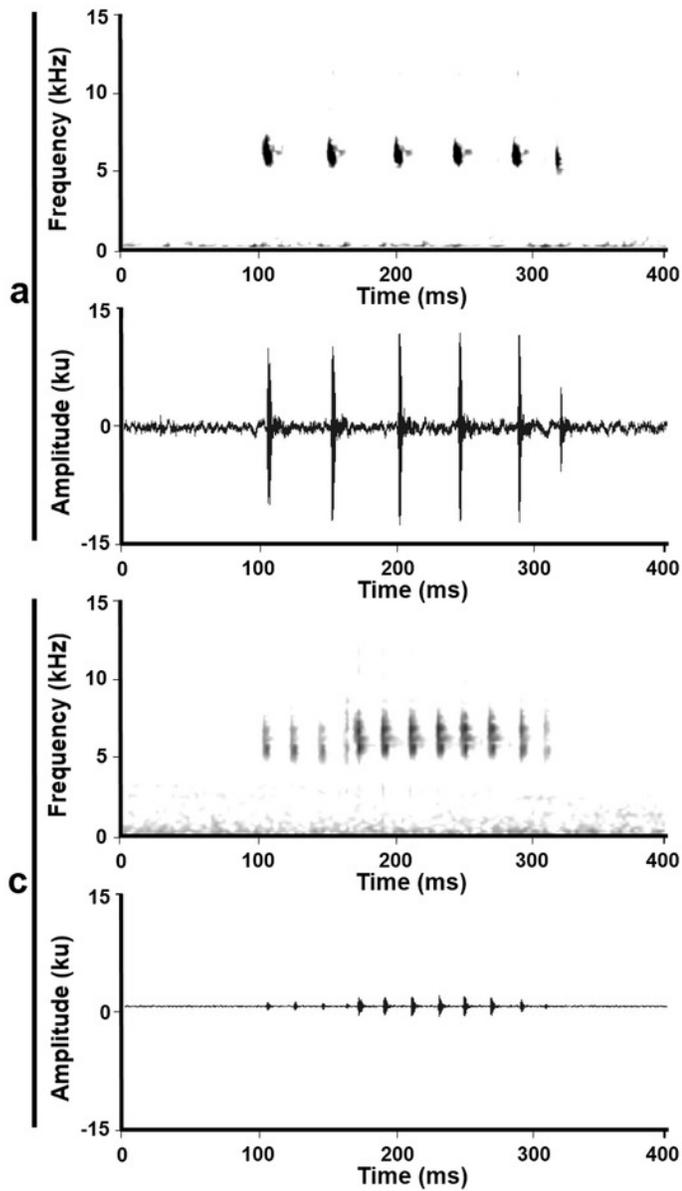

Figure 7

Records of flea toads *Brachycephalus hermogenesi*, *B. sulfuratus*, and of *Brachycephalus* sp.

Figure 7. Records of flea toads *Brachycephalus hermogenesi*, *B. sulfuratus*, and of *Brachycephalus* sp. (*B. hermogenesi* or *B. sulfuratus*), according to the compilation of localities and review of identifications shown in Table 1. We highlighted the southernmost record of *B. hermogenesi* confirmed (1 - Estação Biológica de Boracéia). We also highlight the northernmost confirmed records of *B. sulfuratus* (2 - Núcleo Itutinga-Pilões and 3 - near the Jurupará dam). Abbreviations: RJ = Rio de Janeiro; SP = São Paulo; PR = Paraná; SC = Santa Catarina.
