Inadequate endometrial receptivity may be responsible for the low implantation rate of transferred embryos in *in vitro* fertilization (IVF) treatments. Patients with repeated implantation failure (RIF) impact the clinical pregnancy rate for IVF. We collected endometrial tissue during the implantation window of hysteroscopy biopsies from September 2016 to December 2019 and clinical data were collected simultaneously. Patients were divided into RIF and pregnant controls group according to pregnancy outcomes. A total of 82 differentially expressed endometrial proteins were identified, including 55 up-regulated proteins (>1.50 -fold, $P<0.05$) and 27 down-regulated proteins (<0.67 -fold, $P<0.05$) by iTRAQ labeling coupled with the 2D LC MS/MS technique in the RIF group. String analysis found interactions between these proteins which assembled in two bunches: ribosomal proteins and blood homeostasis proteins. The most significant enriched Gene Ontology terms were negative regulation of hydrolase activity, blood microparticle, and enzyme inhibitor activity. Our results emphasized the corticosteroid-binding globulin and fetuin-A as the specific proteins of endometrial receptivity by Western-blot. Our study provided experimental data to establish the objective indicator of endometrial receptivity, and also provided new insight into the pathogenesis of RIF.

17 18 Abstract

19 Inadequate endometrial receptivity may be responsible for the low implantation rate of
20 transferred embryos in *in vitro* fertilization (IVF) treatments. Patients with repeated implantation
21 failure (RIF) impact the clinical pregnancy rate for IVF. We collected endometrial tissue during
22 the implantation window of hysteroscopy biopsies from September 2016 to December 2019 and
23 clinical data were collected simultaneously. Patients were divided into RIF and pregnant controls
24 group according to pregnancy outcomes. A total of 82 differentially expressed endometrial
25 proteins were identified, including 55 up-regulated proteins (>1.50 -fold, $P<0.05$) and 27 down-
26 regulated proteins (<0.67 -fold, $P<0.05$) by iTRAQ labeling coupled with the 2D LC MS/MS
27 technique in the RIF group. String analysis found interactions between these proteins which
28 assembled in two bunches: ribosomal proteins and blood homeostasis proteins. The most
29 significant enriched Gene Ontology terms were negative regulation of hydrolase activity, blood
30 microparticle, and enzyme inhibitor activity. Our results emphasized the corticosteroid-binding
31 globulin and fetuin-A as the specific proteins of endometrial receptivity by Western-blot. Our
32 study provided experimental data to establish the objective indicator of endometrial receptivity,
33 and also provided new insight into the pathogenesis of RIF.

34 35 Introduction

36 According to the World Health Organization, infertility is most prevalent in South Asia,
37 Sub-Saharan Africa, North Africa/Middle East, Central/Eastern Europe, and Central Asia
38 (Mascarenhas et al., 2012). There is a 25% infertility rate among couples of childbearing age in

39 China (Zhou et al., 2018). Assisted reproductive technology (ART) is currently the most
40 effective method to assist infertile patients (Kushnir et al., 2017).

41 In vitro fertilization and embryo transfer (IVF-ET) are the most common methods of ART.
42 Despite the success of these methods, some patients still have difficulty becoming pregnant even
43 after multiple transplantations (2-6 times) of high-quality embryos. These patients are classified
44 as repeated implantation failure (RIF) patients (Margalioth et al., 2006) and impact the clinical
45 pregnancy rate of ART. Embryo quality, which can be evaluated using several criteria, and
46 endometrial receptivity are the two key factors for successful implantation. Endometrial
47 receptivity is defined as the period during which the endometrial epithelium acquires a
48 functional, but transient, ovarian steroid-dependent status that supports blastocyst acceptance and
49 implantation. This period is called the window of implantation (WOI). Approximately 25.9% of
50 IVF-ET cases have a displaced WOI (Ruiz-Alonso et al., 2013), and the lack of synchronization
51 between the embryo and endometrial receptivity may be one of the causes of RIF. The standard
52 for evaluating endometrial receptivity is the pinopodes in endometrial histology but these can
53 change depending on the sample used and the period in the menstrual cycle (Acosta et al., 2000).
54 Ultrasound examination is a widely used, noninvasive and inexpensive test, and includes
55 endometrial thickness, endometrial type, endometrial volume, and uterine artery and sub-
56 endometrial blood flow. However, ultrasound examination has little ability to predict the
57 pregnancy rate with strong subjectivity. A number of studies have applied omics techniques to
58 analyze the human endometrium along different menstrual cycles, using biopsy or curettage
59 (Bissonnette et al., 2016; Chen et al., 2009; DeSouza et al., 2005; Parmar et al., 2009; Rai et al.,
60 2010; Ruiz-Alonso et al., 2012; Yap et al., 2011). Previous research (Bissonnette et al., 2016;
61 Chen et al., 2009; DeSouza et al., 2005; Parmar et al., 2009; Rai et al.) used proteomic techniques
62 as 2D differentials in-gel electrophoresis (DIGE), Nanobore LC-MS/MS, and MALDI-TOF-TOF
63 to study the endometrium protein changes between the proliferative and secretory phase. Yap et
64 al. (2011) identified IL-11 regulated plasma membrane proteins ANXA2, and the lipid-raft
65 protein FLOT1 in human endometrial epithelial cells in vitro in the receptive phase.

66 We screened differential WOI endometrial proteins using iTRAQ labeling coupled with a
67 2D LC-MS/MS technique to find potential biomarkers for RIF patients. Our study provided
68 experimental data to establish an objective indicator of endometrial receptivity and a new way to
69 reveal the pathogenesis of RIF.

70

71 **Materials & Methods**

72 **Sample collection**

73 This study was approved by the Ethics Committee of the Faculty of Medicine (Hangzhou
74 Women's Hospital, China) (Approval Number: 2016001-10). Written informed consent was
75 obtained from all subjects before endometrial collection.

76 The workflow of our study is shown in Fig. 1. Failure of three or more cycles in which
77 reasonably high-quality embryos were transferred was defined as RIF (Margalioth et al., 2006).
78 Grade I and grade II embryos were determined to be high-quality embryos (Gardner et al., 1998).

79 The blastocyst quality was determined according to the definitions by Gardner et al. (1998).
80 Blastocysts were considered high-quality if they had a grade 3 or 4 blastocoel, a grade A or B
81 inner cell mass, and a grade A or B trophectoderm on days 5 or 6. We collected data from fifty-
82 two RIF cases and 135 pregnancy cases undergoing IVF-ET treatment at our hospital between
83 September 2016 to December 2019. Data including age, follow-up outcomes, and clinical
84 examination findings were collected. The endometrium was collected at WOI by hysteroscopy
85 biopsy at LH+7. The endometrium was then washed with saline immediately and frozen in liquid
86 nitrogen and stored until protein extraction.

87 **Endometrium protein extraction**

88 We randomly selected 2 pregnancy cases and 3 RIF cases for endometrial protein extraction.
89 Protein extraction was performed using a lysis buffer after grinding the sample (100 mg) to
90 powder in liquid nitrogen. Phenylmethanesulfonyl fluoride (PMSF) was added to a final
91 concentration of 1mM and ethylene diamine tetraacetic acid (EDTA) was added to a final
92 concentration of 2mM, held for 5 min, and then dithiothreitol (DTT) was added to a final
93 concentration of 10mM. The sample was placed in an ice bath ultrasound for 5 min and the
94 lysate was centrifuged at 15,000 g for 20 min. The supernatant was precipitated 5 times with 1
95 mL acetone and incubated at 20 °C for 2 h and then centrifuged at 15,000 g at 4 °C for 20 min.
96 The precipitate was washed in chilled acetone, incubated at 20 °C for 30 min, and centrifuged
97 again at 15,000 g and 4 °C for 20 min. The washing was repeated twice, then air dried and the
98 precipitate was re-dissolved with the lysis buffer. The precipitate was centrifuged again at 15,000
99 g and 4 °C for 20 min after an ice bath ultrasound for 5 min. The supernatant was determined
100 using the Bradford Protein Assay Kit to detect the protein concentration.

101 **Protein digestion and iTRAQ-2D LC-MS/MS**

102 A solution of 1:50 trypsin (Promega, USA)-to-protein mass was prepared. Then, a total of
103 100 µg of protein from each group was digested with prepared solution at 37 °C for 16 h. The
104 peptides were reconstituted in 0.2M TEAB and processed according to the manufacturer's
105 protocol for 8-plex iTRAQ reagent (AB SCIEX, Framingham, MA, USA). Three biological
106 replicates of the RIF group were labeled with 113, 114, and 115 isobaric tags, respectively. The
107 peptides with two biological replicates from the pregnant group were labeled with 116 and 117
108 isobaric tags, respectively.

109 A high pH reversed-phase chromatography column (Phenomenex, Gemini-NX 3u C18110A,
110 150*2.00mm) was used for the first-dimensional fractionation procedure. We collected 16
111 fractions in all, and then dried them for next LC-MS analysis. The fractions were re-suspended in
112 2% acetonitrile containing 0.1% formic acid, and then loaded into a C18 trap column (Acclaim
113 PepMap 75µm × 150mm, C18, 3µm, 100A). Then, online chromatography separation was
114 performed on the nanoLC system (Dionex Ultimate 3000 RSLCnano) (Fan et al., 2019). The
115 trapping and desalting procedures were carried out at a flow rate of 3 µL/min for 5 min with 100%
116 solvent A (0.1% formic acid, 2% acet- onitrile and 98% water). The peptides were eluted using a
117 65 min gradient of buffer A (0.1% formic acid) to buffer B (80% ACN containing 0.1% formic
118 acid) at 300 nL/min on an analytical column (Acclaim PepMap 75 µm × 15 cm C18-CL, 3 µm

119 100 Å, Thermo160321). Q Exactive system (Thermo Scientific) fitted with a Nanospray ion
120 source was used to acquire tandem MS data. Specific steps are as follows: data were acquired
121 using an ion spray voltage of 2.2 kV. MS spectra across the scan range of 350–1800 m/z with a
122 70,000 resolution using maximum injection time (60 ms) per spectrum. Twenty of the most
123 intense precursors per MS cycle were selected for fragmentation and were detected with 100 ms
124 maximum injection time. Tandem mass spectra were recorded at a 17,500 resolution with the
125 rolling collision energy turned on and iTRAQ reagent collision energy adjustment turned on. The
126 lock mass option was enabled for more accurate measurements. Dynamic exclusion was set for
127 10 s.

128 Finally, the acquired MS/MS data were analyzed using IPeak and IQuant software as former
129 researchers (Wen et al., 2015; Wen et al., 2014; Fan et al., 2019). Only proteins identified at
130 global FDR $\leq 1\%$ with ≥ 1 peptide were considered for further downstream analysis. A
131 differentially expressed protein was determine only if it is identified and quantified with at least
132 one significant peptide with the $P < 0.05$ and fold change > 1.5 .

133 **Bioinformatics analysis**

134 Principal components analysis (PCA) was performed to confirm the sample repeatability.
135 Functional annotation was performed using the Gene Ontology (GO) database
136 (<http://www.geneontology.org>) and included the cellular component, molecular function, and
137 biological process. The differentially expressed protein–protein network was analyzed by
138 STRING software (<http://www.string-db.org/>). The Kyoto Encyclopedia of Genes and Genomes
139 (KEGG) database (<http://www.genome.jp/kegg/or> <http://www.kegg.jp/>) was used to predict the
140 main metabolic pathways (Kanehisa et al., 2007). We obtained the significantly enriched
141 GO/pathway items by hypergeometric test. The EggNOG database (<http://eggnogdb.embl.de>)
142 was used for pairwise orthology predictions, functional annotation, and classification (Huerta-
143 Cepas et al., 2015).

144 **Western-blot analysis**

145 We lysed endometrial tissues with 200 μL of RIPA lysate (P0013B, Beyotime, Shanghai,
146 China) plus 1mM PMSF at 4 °C for 30 min, and then harvested the supernatant with
147 centrifugation at 11,000 g for 10 min. The harvested protein concentrations were measured with
148 a BCA quantitative kit (P0009, Beyotime). Samples were subjected to polyacrylamide gel
149 electrophoresis, and were transferred onto a PVDF membrane (IPVH00010, Millipore,
150 Massachusetts, USA). The membrane was blocked by 5% skimmed milk powder solution at
151 room temperature for 2 h and was incubated with primary antibodies, including antithrombin III
152 (rabbit monoclonal, ab126598, abcam, Cambridge, United Kingdom), cortisol binding globulin
153 (rabbit monoclonal, ab110648, abcam), fetuin-A (alpha-2-HS-glycoprotein, rabbit monoclonal,
154 ab137125, abcam), GAPDH (mouse monoclonal, 60004-1-Ig, proteintech, Beijing, China), and
155 alpha tubulin (rabbit polyclonal, 11224-1-AP, proteintech) at 4 °C overnight. Secondary
156 antibodies as goat anti-mouse IgG-HRP (BK0023, BEST, Xian, China) and goat anti-rabbit IgG-
157 HRP (BK0027, BEST) were then incubated with membrane at room temperature for 1.5 h. The

158 blots were visualized using the ECL Plus Luminous Kit (S17851, Yeasen, Shanghai, China). At
159 last, the results were measured with Image J software.

160 **Statistical analysis**

161 Parametric data were tested using the chi-square test for the composition ratios and t-tests
162 for means of two groups. Nonparametric analysis was carried out using the Mann–Whitney U-
163 test. Parametric data were presented as mean \pm SD while nonparametric data were presented as
164 median \pm IQR, and $P < 0.05$ was considered to be statistically significant by the SPSS software,
165 version 16.0 (SPSS, Chicago, IL). Our clinical data was able to identify significant differences in
166 81.45% of RIF cases and controls at a statistical support level of $\alpha=0.05$ with a $d = 0.5$ applying
167 a one tail model calculated by Gpower 3.0.5.

168

169 **Results**

170 **Clinical data analysis**

171 We recruited 52 RIF patients and 135 pregnant patients undergoing IVF-ET treatment
172 between September 2016 to December 2019. Data, including age, follow-up outcomes, and
173 clinical examination findings were collated into databases. After correcting for age, since age
174 may affect the pregnancy rate, a total of 40 subjects with RIF under 40 years old were paired
175 with 80 pregnant subjects by age, body mass index, and treatment time and then analyzed. There
176 were no significant differences between RIF patients and pregnant controls in general and
177 clinical data ($P>0.05$, Table 1).

178 **Endometrial proteomics results**

179 We identified a total of 6,102 proteins through iTRAQ-2D LC-MS/MS from 113,384
180 spectra and 31,024 peptides, respectively (Supplementary Table 1). Among the 6,102 identified
181 proteins, 5,840 had GO annotations (95.71% of all proteins); 5,504 had KEGG annotations
182 (90.20% of all proteins); and 6,097 had EggNOG annotations (99.92% of all proteins).

183 We performed quality control on the quantitative results with volcano maps and the
184 distributions of coefficient of variation. We selected the fold change for 6,102 proteins and found
185 285 proteins with fold change in RIF cases/pregnant controls >1.5 or <0.67 . And we only used
186 proteins with $P < 0.05$. Further screening revealed 82 differentially expressed proteins in RIF
187 patients compared with the pregnant controls, including 55 up-regulated proteins (>1.50 -fold,
188 $P<0.05$) and 27 down-regulated proteins (<0.67 -fold, $P<0.05$) (Table 2). The hierarchical
189 clustering provided a visualized mode to display the clustering patterns of the differentially
190 expressed proteins between the groups (Fig. 2).

191 **Bioinformatics analysis results**

192 Gene Ontology analysis of differentially expressed proteins revealed that most of the
193 proteins were involved in the response to stimulus (42 proteins), extracellular region (35
194 proteins), and structural molecule activity (10 proteins) (Fig. 3A). The most significantly
195 enriched GOs were negative regulation of hydrolase activity, blood microparticle, and enzyme
196 inhibitor activity through hypergeometric testing (Figure 3B). Seven proteins (SPB6, APOA1,

197 GMIP, THBG, CBG, ANT3, and FETUA) were identified in the hydrolase activity term, seven
198 proteins (VTDB, IGHG4, APOA1, A1AG2, FETUA, ANT3, and A1AG1) were identified in the
199 blood microparticle term, and another seven proteins (ANT3, FETUA, CBG, ASPN, SPB6,
200 THBG, and APOA1) were identified in the enzyme inhibitor activity term. Among these
201 proteins, ANT3 and FETUA were identified in prior studies (Hannan et al., 2010; DeSouza et al.,
202 2005) which played an important molecular function in endopeptidase inhibitor activity by GO
203 analysis (Fig. 3C). String analysis found interactions between these proteins (Fig. 3D) which
204 assembled in two bunches: ribosomal proteins and blood homeostasis proteins.

205 In addition, the KEGG pathway mapping revealed the immune system (seven proteins),
206 transport and catabolism (five proteins), and translation (five proteins) pathways (Fig. 4A).
207 Enriched KEGG pathway analysis showed the ribosome and primary immunodeficiency
208 pathways as significant with $P < 0.05$ (Fig. 4B). Finally, we used the EggNOG database to
209 determine that the differential proteins associated with RIF are mostly clustered in classifications
210 including posttranslational modification, protein turnover, chaperones (22 proteins), translation,
211 ribosomal structure and biogenesis (eight proteins), and carbohydrate transport and metabolism
212 (six proteins) (Fig. 4C).

213 **Western-blot results**

214 We verified endometrial antithrombin-III (ANT3, P01008), corticosteroid-binding globulin
215 (CBG, P08185), and fetuin-A (FETUA, P02765) levels using the Western-blot. We found
216 significantly higher levels of CBG and fetuin-A in RIF patients (Fig. 5). A significant difference
217 in CBG and fetuin-A was found in RIF patients using grayscale detection by Image J (1.39 fold,
218 $P = 0.003$; 1.47 fold, $P = 0.002$; respectively).

219

220 **Discussion**

221 Assisted reproductive technology has made rapid progress over the last 40 years. However,
222 the clinical pregnancy rate still only ranges between 33.8 and 42.7% (European IVF-Monitoring
223 Consortium (EIM) for the European Society of Human Reproduction and Embryology (ESHRE)
224 et al., 2016; Sunderam et al., 2019). After the implementation of blastocyst transplantation, the
225 clinical pregnancy rate increased to 60.4% (Ozgur et al., 2018). RIF is the key factor affecting
226 the pregnancy rate in IVF. Embryo quality, uterine factors (uterine cavity lesions, adenomyosis,
227 endometrial receptivity, etc.), immune factors (embryo immunity, maternal immunity), and a
228 multifactor effect could all lead to RIF but inadequate endometrial receptivity is the major cause
229 of decreased pregnancy success in RIF patients. We collected the endometrium of IVF-ET
230 patients during WOI and divided the samples into the RIF group and pregnant control group
231 according to pregnancy outcomes. Specific proteins related to endometrial receptivity were
232 screened using iTRAQ-2D LC-MS/MS.

233 Through iTRAQ-2D LC-MS/MS and bioinformatics analysis, 82 differential proteins were
234 obtained in the endometrium of RIF patients during the WOI, of which 55 were higher (> 1.50
235 times, $P < 0.05$) in RIF patients and 27 were lower (< 0.67 times, $P < 0.05$) in RIF patients. The
236 differential proteins obtained in this study have also been identified in the early proteomic

237 studies. Hannan et al. obtained seven differential proteins of the uterine lavage fluid of
238 pregnant/non-pregnant patients in the WOI by 2D-DiGE. The antithrombin III (ANT3, P01008)
239 was significantly increased in non-pregnant patients by immunohistochemistry (Hannan et al.,
240 2010). We found that the expression of ANT3 was 1.77 times as much as that in the pregnant
241 group, which was similar to previous results, indicating the reliability of iTRAQ-2D LC-MS/MS.
242 The results for ANT3, alpha-1-acid glycoprotein 1 (P02763), vitamin D-binding protein
243 (P02774), and FETUA (P02765) were also consistent with previous studies on the menstrual
244 phase (DeSouza et al., 2005). Ribosomal proteins and apolipoproteins have also been identified
245 in ours and other previous studies (DeSouza et al., 2005; Domínguez et al., 2009; Pérez-Deben et
246 al., 2019).

247 The differentially expressed proteins were related to the immune system and primary
248 immunodeficiency revealing by KEGG analysis and KEGG enrichment analysis (Fig. 3A, 3B).
249 Therefore, the change of immune response in RIF patients is self-evident. It has been shown that
250 the abnormal and functional defects of immune cells and molecules in endometrium during
251 implantation can lead to pregnancy failure (Liu et al., 2016). Therefore, we suspect that the
252 change of the endometrial immune microenvironment may lead to RIF, and may lead to a better
253 clinical treatment for RIF patients.

254 Our study revealed that most of the differentially expressed proteins were annotated with
255 “posttranslational modification, protein turnover, chaperones” and “translation, ribosomal
256 structure and biogenesis function” based on the EggNOG database, except for those with
257 “function unknown”. So, we have reason to believe that modification after translation, synthesis
258 and degradation, folding, maintenance, intracellular transport, and mRNA translation might be
259 the key functions changed in embryo implantation. The results of enriched KEGG and String
260 analysis in our study also confirmed that translation was impacted.

261 The proteins in the most significantly enriched GOs contained ANT3 and FETUA, which
262 was consistent with results from previous studies (DeSouza et al., 2005; Hannan et al., 2010).
263 ANT3 was also related to the immune system as highlighted in the KEGG analysis. These
264 proteins were selected as candidates for validation. Protein was also selected based on a review
265 of the literature as CBG. Misao et al. (1995) suggested that the decrease of progesterone level in
266 the blood can lead to an increased CBG expression level in the endometrium. Low progesterone
267 levels may lead to higher miscarriage rates and lower live birth rates in frozen embryo transfer
268 patients (Gaggiotti-Marre et al. 2019).

269 Antithrombin-III is a representative protein of the prethrombotic state, which is encoded by
270 ANT3. The prethrombotic state is thought to be a major cause of RIF (Qublan et al., 2006). Our
271 proteomics results corroborated those of Hannan et al. (2010), which revealed up-regulated
272 levels of antithrombin III in non-pregnant patients (Hannan et al., 2010). However, antithrombin
273 III showed no significant difference in RIF patients and pregnant controls. These differences may
274 be due to the differences in the validation tests used. We used the quantitative Western-blot for
275 validation while Hannan et al. used immunohistochemical localization. Therefore, antithrombin
276 III may not change in RIF patients.

277 Corticosteroid-binding globulin was a multifaceted component in cortisol delivery, also in
278 acute and chronic inflammation, and metabolism and neurocognitive function (Meyer et al.,
279 2016). The increased CBG level during pregnancy was important at the materno-fetal interface
280 (Lei et al., 2015). We found significantly higher levels of CBG in RIF patients (Fig. 4). Misao et
281 al. (1995) suggested that the decrease of progesterone levels in the blood may increase CBG
282 expression in the endometrium. However, we found a lower level of serum progesterone in RIF
283 patients, but the difference was not significant (Table 1) and a larger sample of research may be
284 needed. The endometrial CBG content is thought to originate in the plasma (Kreitmann et al.,
285 1978), thus, RIF patients may have a positive outcome with supplemental progesterone
286 administration.

287 Fetuin-A is defined as the inhibitor of ectopic calcification in circulation, which also takes
288 part in multiple metabolic pathways such as insulin resistance, vascular calcification, and
289 inflammation (Bilgir et al., 2010; Ishibashi et al., 2010; Wang et al., 2012). Fetuin-A is also
290 popular in studies on adverse pregnancy outcomes like pre-eclampsia (Sanhal et al., 2016) and
291 gestational diabetes mellitus (Kansu-Celik et al., 2019). A previous study on pre-eclampsia
292 concluded that fetuin-A may decrease trophoblast viability and invasion caused by the inhibition
293 of receptor tyrosine kinase activity (Gomez et al., 2012). Our study supported the results that
294 showed that elevated fetuin-A may lead to failed implantation and cause an adverse pregnancy
295 outcome. Meanwhile, Ozgu-Erdinc et al. (2020) demonstrated that serum fetuin-A level were
296 also increased in implantation failure patients in IVF cycles. Additional studies on the regulation
297 of the level of fetuin-A as a treatment strategy may improve implantation success.

298

299 **Conclusions**

300 We screened the endometrial proteomics of RIF patients using iTRAQ-2D LC-MS/MS at
301 WOI, revealing that the endometrial immune microenvironment may lead to RIF. Our validated
302 results confirmed CBG and fetuin-A as the specific protein for RIF patients. Our results provide
303 experimental data to establish the objective indicator of endometrial receptivity and give a new
304 insight into the pathogenesis of RIF.

305

Q8NGY6	OR6N2	Olfactory receptor 6N2	0.66

Figure 1

The workflow for endometrial biomarkers of repeated implantation failure (RIF) and pregnant controls (CON).

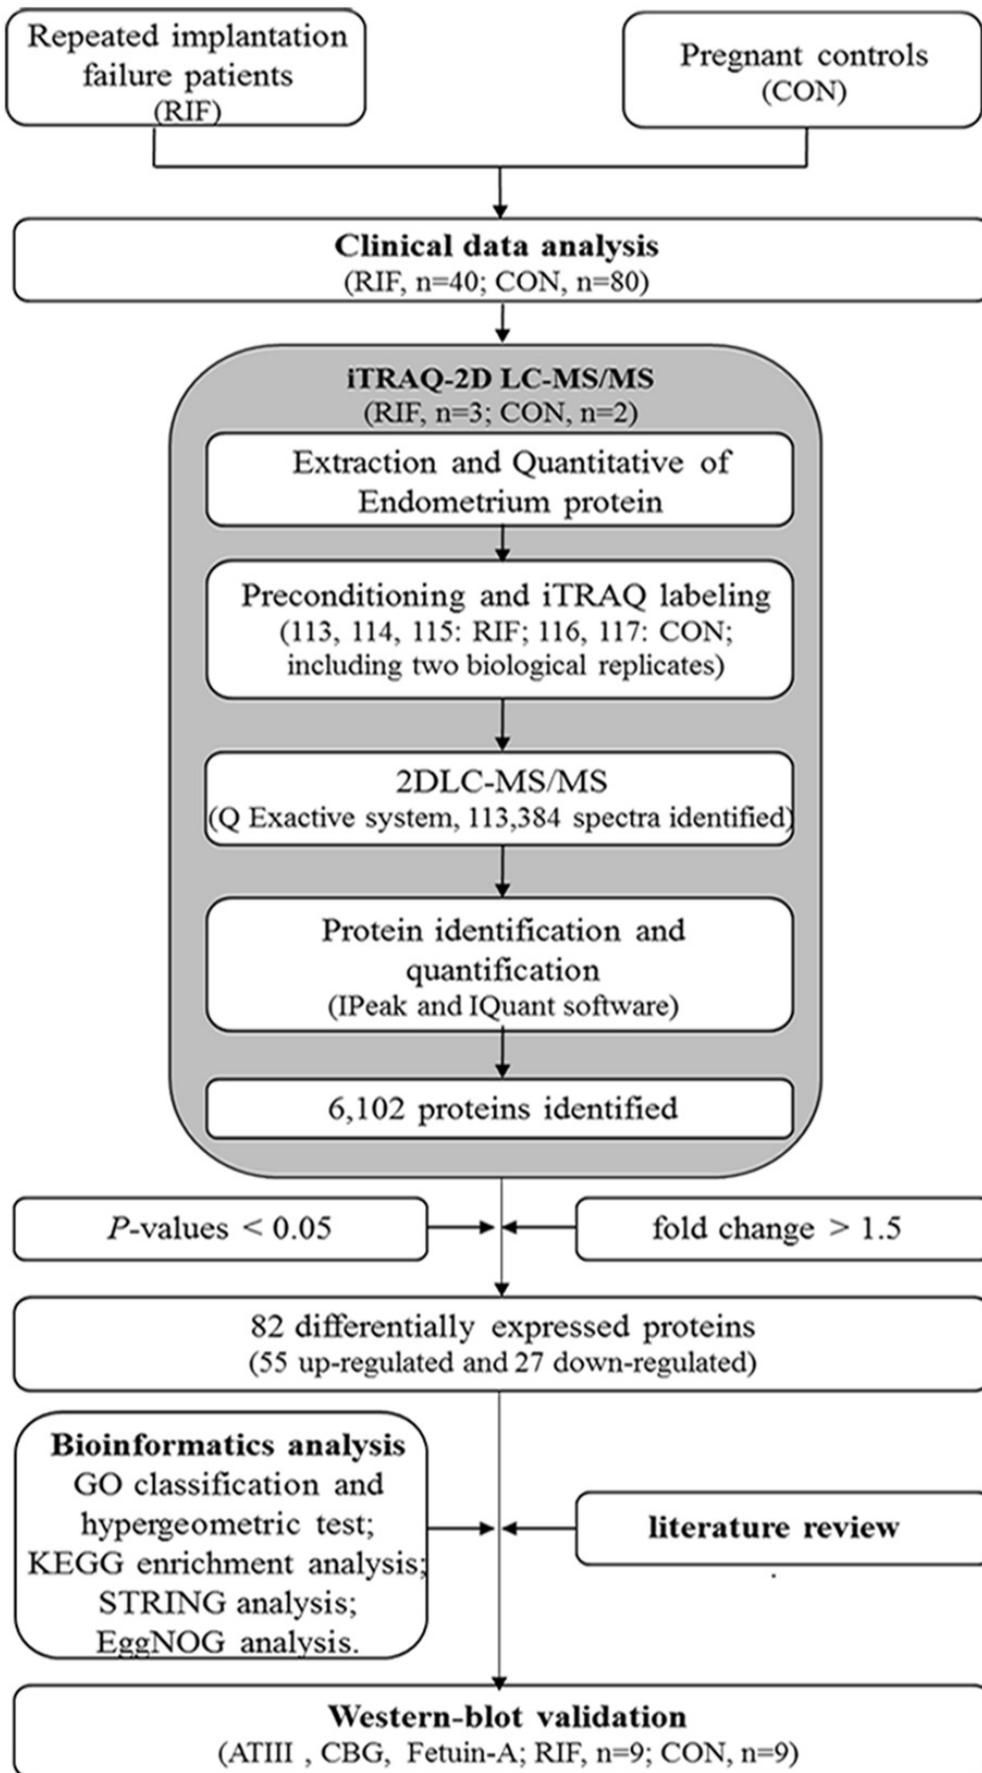

Figure 2

The hierarchical clustering for endometrium proteins between repeated implantation failure (RIF) and pregnant controls (Con) groups.

The red color showed the up-regulated expression, and the blue color represented the down-regulated expression. The color from red/blue to white represented the ratio from large to small.

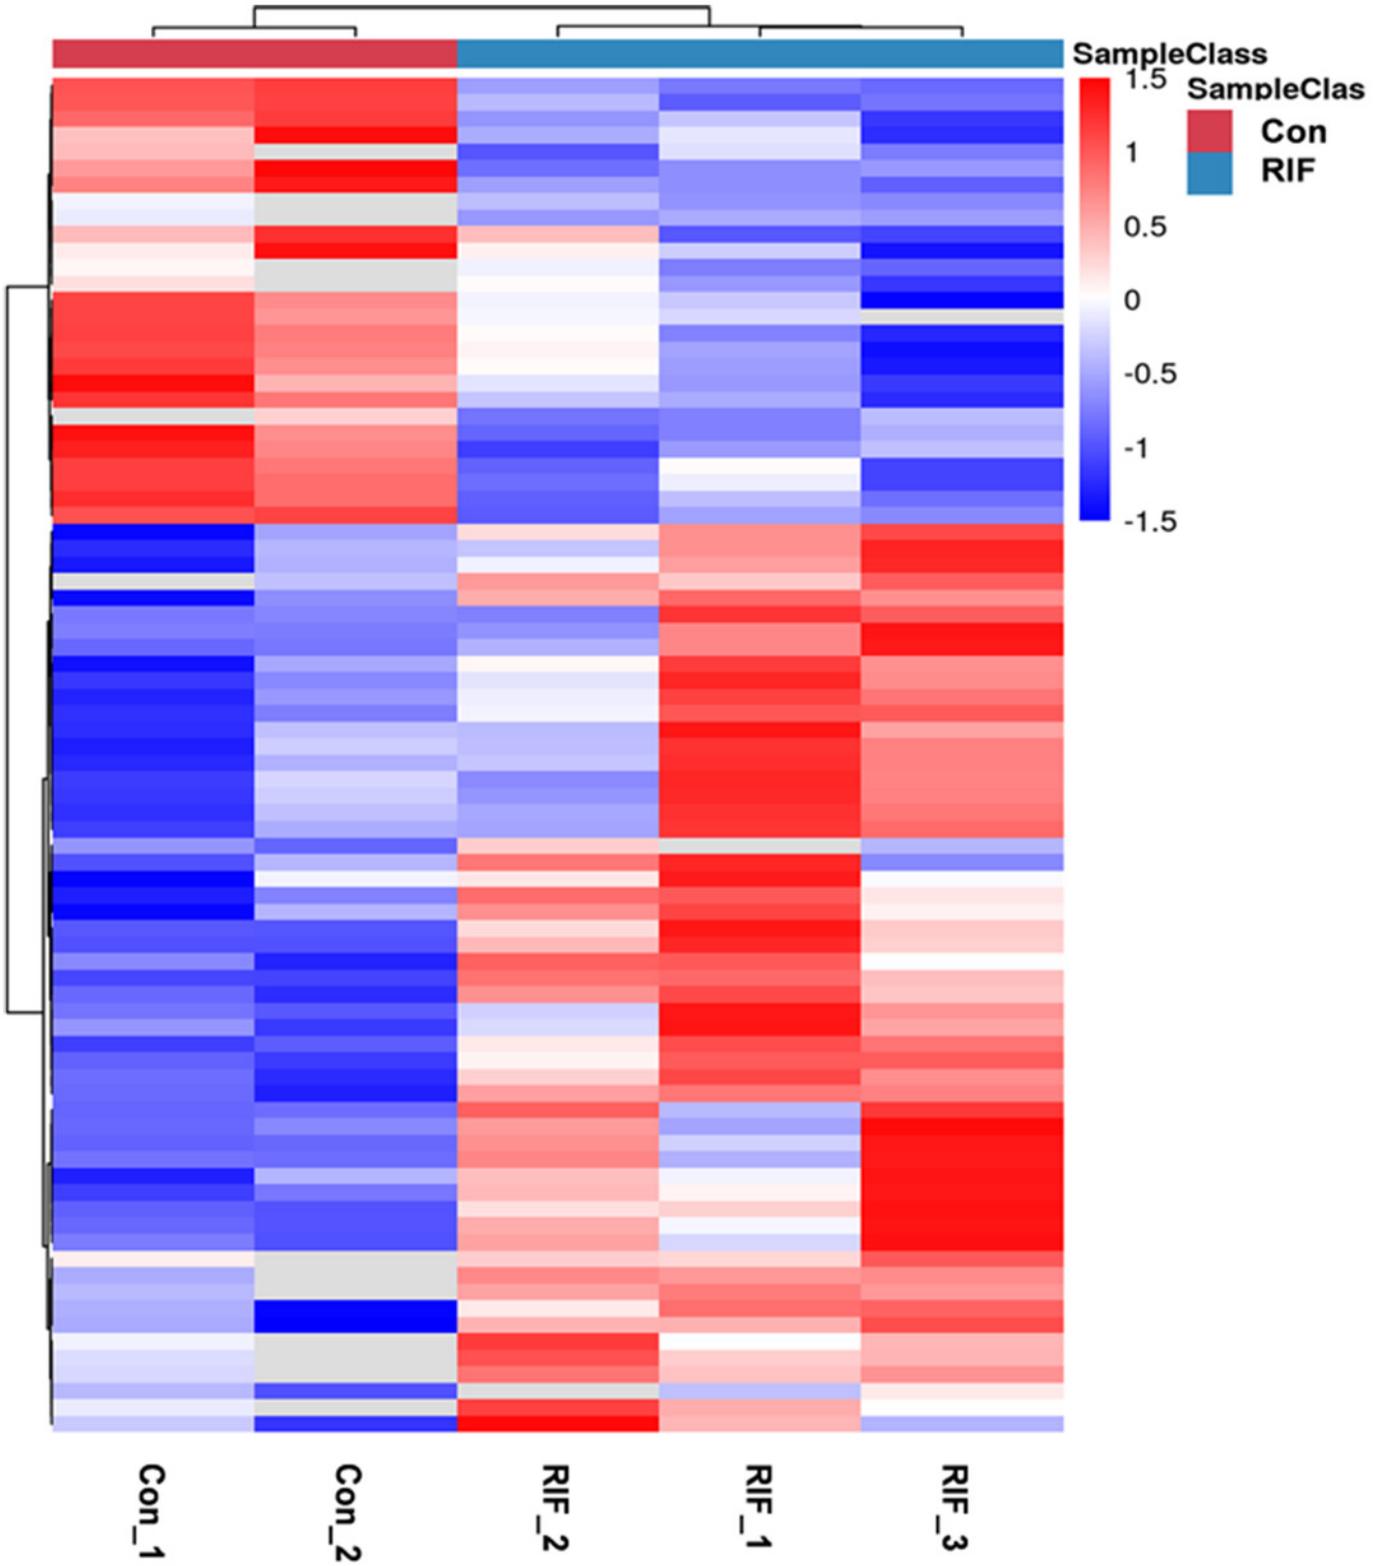

Figure 3

GO analysis and String analysis of the set of endometrium proteins biomarker candidates for repeated implantation failure.

(A) GO analysis of 82 differentially expressed proteins revealed 7 significant GO terms in biological process, 11 significant GO terms in cellular component, and 2 significant GO terms in molecular function ($P < 0.05$). (B) The enrichment analysis revealed 20 significant GO terms by hypergeometric test ($P < 0.05$). GO terms with bigger enrichment factor indicate the greater degree of enrichment. (C) Molecular function of GO terms for proteins identified both in our and prior studies. (D) Network nodes represent proteins while edges represent protein-protein associations which were already known (light blue and purple) or predicted (other colors) by String analysis. Proteins enclosed in color-coded outlines are mainly involved in ribosomal proteins (yellow) and blood homeostasis proteins (blue).

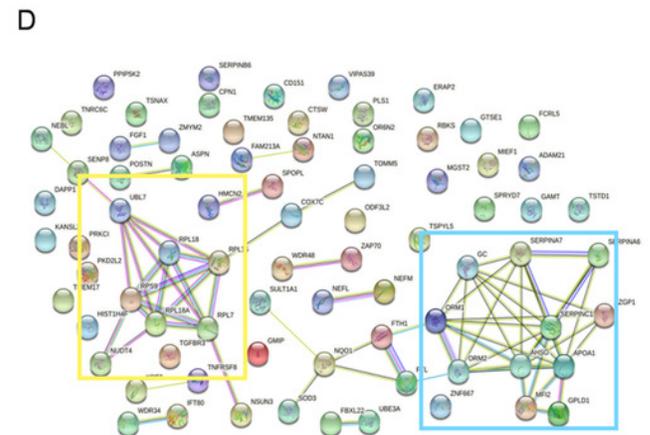

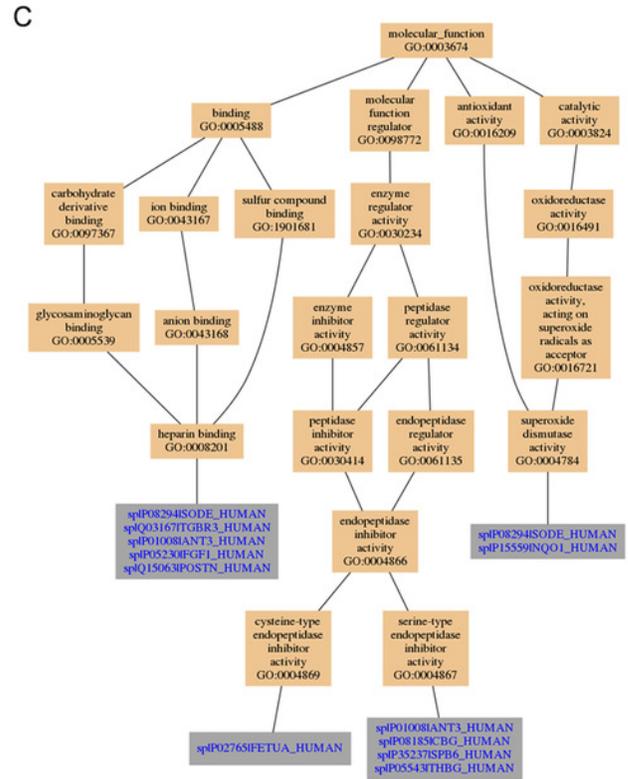

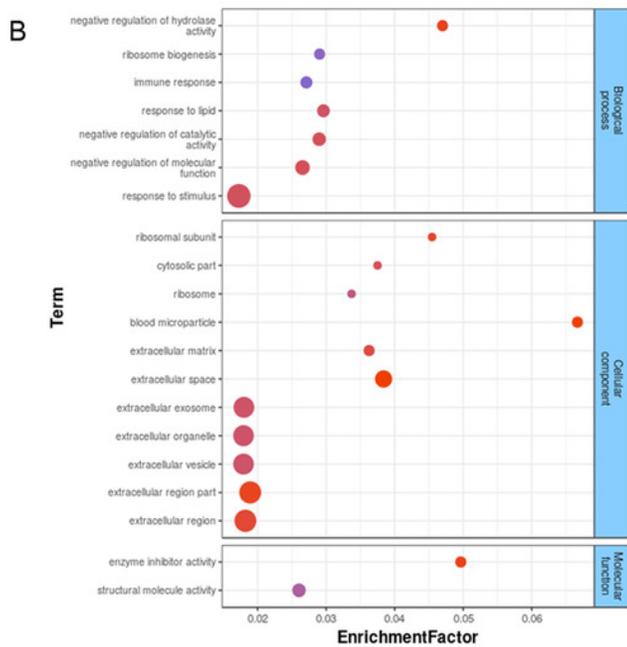

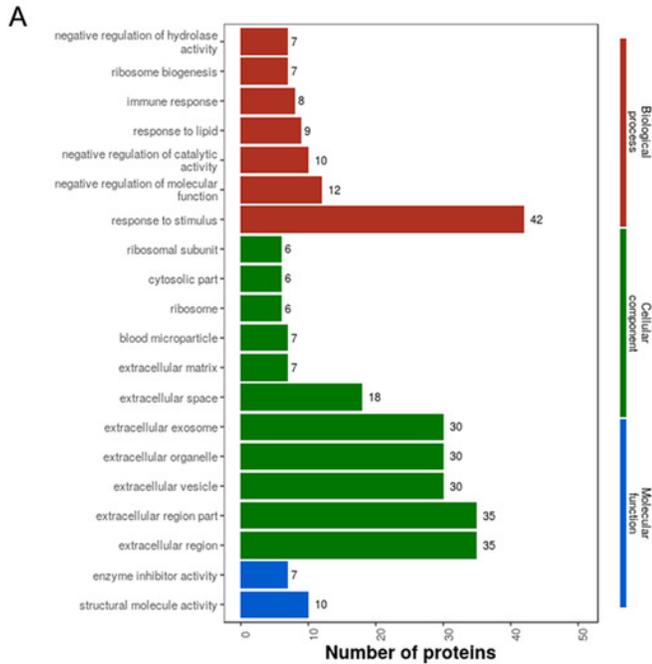

Figure 4

KEGG analysis and EggNOG analysis of the set of endometrium proteins biomarker candidates for repeated implantation failure.

(A) KEGG pathway analysis of 82 differentially expressed proteins using KEGG database revealed 35 pathways. (B) The enrichment analysis of KEGG pathways revealed 10 significant pathways by hypergeometric test ($P < 0.05$). Pathways with bigger rich factor indicate the greater degree of enrichment. (C) EggNOG analysis predicted pairwise orthology and functional classification for 82 differentially expressed proteins.

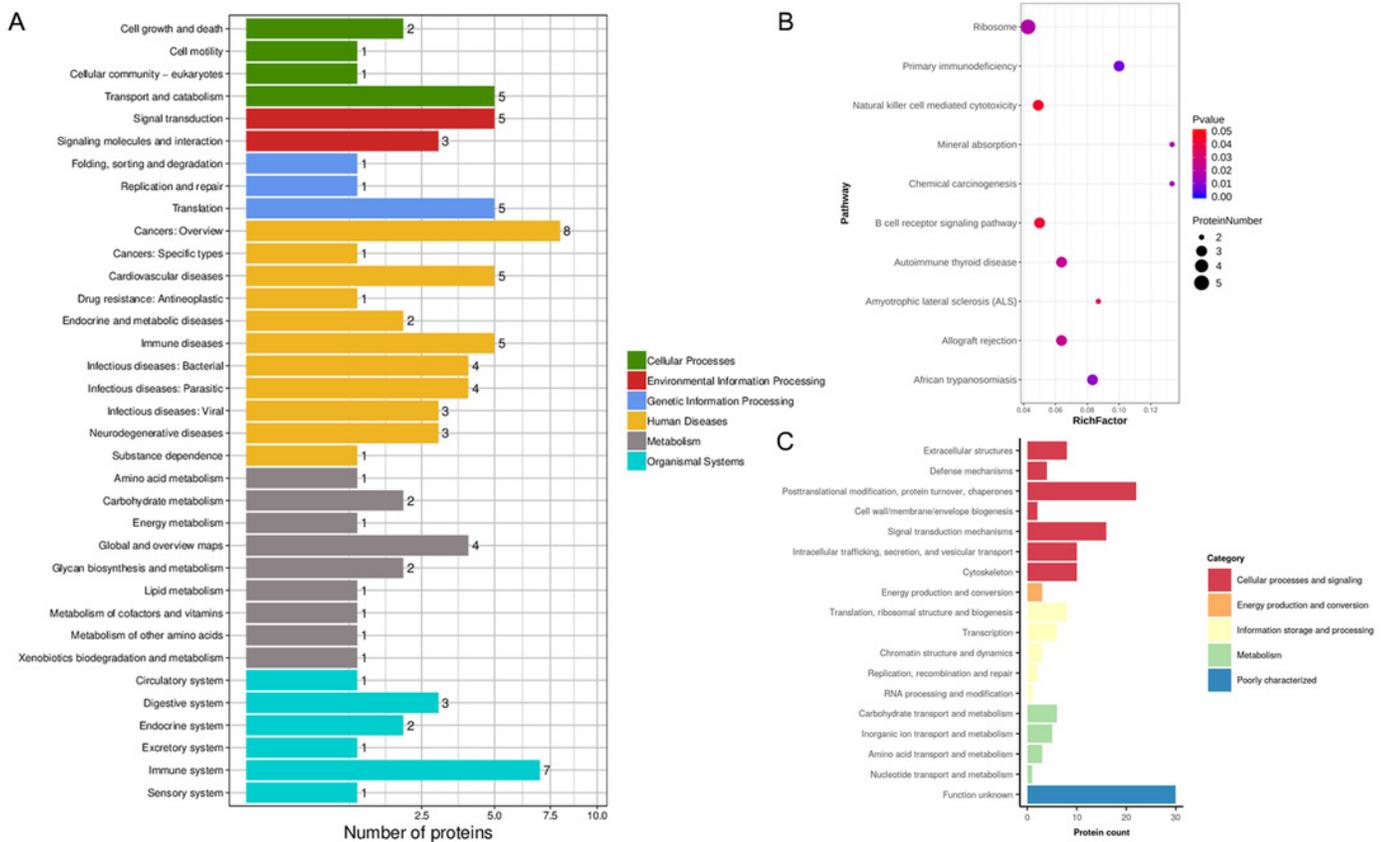

Figure 5

Proteins expression levels change between repeated implantation failure (RIF) and pregnant controls (CON).

(A) antithrombin III (ATIII) (52 KDa); (B) corticosteroid-binding globulin (CBG) (45 KDa); and (C) fetuin-A (39 KDa) were analyzed by western-blot in nine cases of pregnant controls (CON) and repeated implantation failure (RIF) patients. Beside each western-blot picture, grayscale analysis is represented where the intensity of each protein band is compared to a GAPDH/tubulin band. Grayscale analysis showed a similar tendency to the iTRAQ analysis, with a higher protein abundance of CBG in RIF cases (1.39 fold, $P=0.003$), also higher fetuin-A (1.47 fold, $P=0.002$).
