Underwater videos ($n = 216$) from SharkCam, a camera installation sited beneath Frying Pan Tower on a natural, hard bottom site off Cape Fear, North Carolina, were used to investigate association behavior of round scad *Decapterus punctatus* around sand tiger sharks *Carcharias taurus*. Videos containing sand tiger sharks were analyzed for the simultaneous presence of round scad, and six species of scad mesopredators, with scad-shark interactions assigned to one of three categories of association: no visible interaction, loosely associated, or tightly associated. The likelihood of scad being loosely or tightly associated with sharks was significantly higher in the presence of scad mesopredators, suggesting that sharks provide a predation refuge for scad. This behaviorally-mediated indirect interaction has important implications for trophic energy transfer and mesopredator control on hard bottoms, as scad are one of the most important planktivorous fish in the western Atlantic Ocean. Although we were not able to provide statistical evidence that sand tiger sharks also benefit from this association behavior, we have strong video evidence that round scad association provides concealment and attraction of mesopredators that enhances predation opportunities for sand tiger sharks. This likely possibility adds further trophic consequences to this unique interaction and highlights the value of exploring behaviorally mediated interactions in marine communities.

15 **Abstract**

16 Underwater videos (n = 216) from SharkCam, a camera installation sited beneath Frying Pan
17 Tower on a natural, hard bottom site off Cape Fear, North Carolina, were used to investigate
18 association behavior of round scad *Decapterus punctatus* around sand tiger sharks *Carcharias*
19 *taurus*. Videos containing sand tiger sharks were analyzed for the simultaneous presence of
20 round scad, and six species of scad mesopredators, with scad-shark interactions assigned to one
21 of three categories of association: no visible interaction, loosely associated, or tightly associated.
22 The likelihood of scad being loosely or tightly associated with sharks was significantly higher in
23 the presence of scad mesopredators, suggesting that sharks provide a predation refuge for scad.
24 This behaviorally-mediated indirect interaction has important implications for trophic energy
25 transfer and mesopredator control on hard bottoms, as scad are one of the most important
26 planktivorous fish in the western Atlantic Ocean. Although we were not able to provide
27 statistical evidence that sand tiger sharks also benefit from this association behavior, we have
28 strong video evidence that round scad association provides concealment and attraction of
29 mesopredators that enhances predation opportunities for sand tiger sharks. This likely possibility
30 adds further trophic consequences to this unique interaction and highlights the value of exploring
31 behaviorally mediated interactions in marine communities.

32

33 **Introduction**

34 Hard bottom reefs, or “live bottoms” are conspicuous geological features on the mainly soft
35 sediment-dominated continental shelf within the South Atlantic Bight (SAB). In the Carolina
36 Capes region of the SAB (offshore of North and South Carolina) (Riggs et al., 1996) estimates of
37 areal coverage for this habitat vary on both latitudinal and longitudinal bases, with reports of the

38 greatest areal proportions of hard bottom habitat of the shelf to the south of Cape Lookout, North
39 Carolina (Parker, Colby & Willis, 1983; SAFMC, 1998). Hard bottoms provide structural habitat
40 for the settlement of benthic sessile foundation species, including rich assemblages of sponges,
41 scleractinian and octocorallian corals, ascidians, and macroalgae (Struhsaker, 1969; Miller &
42 Richards, 1980; Wenner et al., 1983). The growth of these sessile organisms contributes to hard
43 bottom reef structural complexity. Compared to adjacent soft-sediment dominated areas of the
44 sea floor, hard bottoms create a striking contrast in habitat that attracts and supports high
45 richness and abundance of fishes (Sedberry & Van Dolah, 1984; Hopkinson, Jansson &
46 Schubauer-Berigan, 1991), invertebrates (Wenner et al., 1983; Peckol & Searles, 1984), and
47 macroalgae (Schneider & Searles, 1973, 1991; Schneider, 1976; Freshwater & Idol, 2013).
48 Specifically, hard-bottom reefs attract aggregations of small pelagic schooling fishes that serve
49 as important prey resources for many pelagic and demersal piscivorous fishes (Kracker, Kendall
50 & McFall, 2008).

51 The abundance and taxonomic richness of species on hard bottoms facilitate unique
52 interspecies interactions that are often driven by enhanced feeding opportunities or decreased
53 vulnerability to predators (McFarland & Kotchian 1982, Diamant and Shpigel 1985, Baird
54 1993). For example, associations between blue runner (*Caranx crysos* (Mitchill, 1815)), greater
55 amberjack (*Seriola dumerili* (Risso, 1810)), and other large piscivorous fishes have been
56 observed during coordinated predatory foraging (Auster et al., 2009). Effects of such
57 associations containing multiple predators on prey mortality has been heavily debated and
58 several studies have reported both additive and reduced predation effects (reviewed in Sih,
59 Englund & Wooster, 1998).

60 Multispecies interactions highlight the underlying interdependency between organisms that
61 exist in all communities (Hutchinson, 1959; Paine, 1984; Beard & Dess, 1988). These
62 interactions are often categorized as direct, between two species, or indirect, where the
63 interaction between two species ultimately affects a third species (Wootton, 1993). Behaviorally
64 mediated indirect interactions (BMIs) are a further classification of trait mediated indirect
65 interactions (TMIs) that are regulated by changes in a species' behavior (Dill, Heithaus &
66 Walters, 2003). Both direct and indirect interactions produce changes in a species' density or
67 behavior and are useful in understanding food webs and trophic exchanges. Indeed, indirect
68 affects alter the risk landscapes of prey, including mesopredators which are prey species for apex
69 carnivores (Ritchie & Johnson, 2009), especially in aquatic ecosystems (Preisser, Bolnick &
70 Benard, 2005), and can initiate trophic cascades (Schmitz, Krivan & Ovadia, 2004; Creel &
71 Christianson, 2008). However, BMIs are less commonly investigated than other ecologic
72 interactions because of the difficulty attributed to quantifying changes in behavior, especially
73 within marine habitats. Competitor facilitation has been used to refer to BMIs where the
74 presence of one species of predator causes a change in the behavior of a prey species that makes
75 that prey species more accessible for a second species of predator (Dill, Heithaus & Walters,
76 2003).

77 On hard bottoms off the coast of Georgia, competitive facilitation was observed as schools of
78 round scad (*Decapterus punctatus* (Cuvier, 1829)) and tomtate (*Haemulon aurolineatum* Cuvier
79 in Cuvier and Valenciennes, 1830) retreated from multispecies associations of pelagic
80 piscivorous fish toward the seafloor, increasing predation opportunities for demersal piscivorous
81 fishes (Auster et al., 2009, 2013) Furthermore, Auster et al. (2009) observed round scad and
82 tomtate responding to the presence of pelagic predators by reducing nearest neighbor distance

83 and forming more polarized aggregations. Increased polarization is a common response to
84 predators for many prey species that form aggregations and has been found to reduce the
85 vulnerability of prey aggregations (reviewed in Lima & Dill, 1990). In addition to increasing
86 polarization, prey fishes use several other strategies to reduce vulnerability to predators.
87 Alternative strategies include forming aggregations around physical objects, which is
88 hypothesized to be advantageous to prey by serving as a “schooling companion” (Klima &
89 Wickham, 1971). During diving observations analyzing the attraction of pelagic fishes to fish
90 aggregation devices (FADs), the removal of artificial structure initiated immediate multispecies
91 predation attempts by large, pelagic, piscivorous fish on small bait fishes (Wickham, Jr & Ogren,
92 1973).

93 *Sand tiger sharks (STs)*

94 Sand tiger sharks, *Carcharias taurus* Rafinesque, 1810, are large (to >4 m), heavy-bodied
95 sharks found in coastal and continental shelf waters of warm-temperate and tropical seas
96 worldwide. Individuals and aggregations occur especially in coastal areas of Australia (where
97 they are known locally as grey nurse sharks), the east coast of South Africa (raggedtooth sharks),
98 and the east coast of the United States (sand tiger sharks). Sand tiger shark aggregations are
99 associated with migratory behavior, feeding, and reproduction (Compagno, 2001), and complex
100 social networks and behaviors are present in this species (Haulsee et al., 2016). Year-to-year site
101 fidelity on shipwrecks and other artificial structures has been reported in North Carolina (Paxton
102 et al., 2019) and animals tagged in Delaware Bay undergo long-distance migrations to
103 overwinter in continental shelf waters of North Carolina (Teter et al., 2015). Additionally, sand
104 tiger sharks are one of the few large-bodied sharks commonly housed in captivity (Govender,
105 Kistnasamy & Van Der Elst, 1991; Gordon, 1993; Smale et al., 2012).

106 The diet of *C. taurus* is diverse and dominated by bony fishes and other elasmobranchs
107 (Gelsleichter, Musick & Nichols, 1999). The conservation status of *C. taurus* is listed as globally
108 vulnerable with regional populations considered endangered or critically endangered (Pollard &
109 Smith, 2009). Assessment of *C. taurus* in the northwestern Atlantic suggests that populations
110 have declined to a minor extent in recent decades (Carlson et al., 2009), much less dramatically
111 than for other large sharks (Ferretti et al., 2010), but that conservative management is warranted
112 due to the very low productivity for this species (Goldman, Branstetter & Musick, 2006; Carlson
113 et al., 2009).

114 *Round scad (RS)*

115 Round scad, *Decapterus punctatus* (Cuvier, 1829), are small-bodied (<300 mm) carangids
116 found in the western Atlantic Ocean southward from Nova Scotia, at Bermuda, and in the Gulf of
117 Mexico, Caribbean Sea, and along continental shores of South America to Rio de Janeiro
118 (Naughton, Saloman & Vaught, 1986). In the South Atlantic Bight, round scad (typically 60–170
119 mm) are abundant in continental shelf waters in summer and fall, and move to hard bottoms in
120 deeper, warmer areas of the mid- and outer shelf in winter (Hales Jr., 1987). Throughout their
121 range, adult round scad are diurnal zooplankton specialists with the diet dominated by pelagic
122 species and life stages (for meroplankton), as opposed to demersal plankton (Hales Jr., 1987;
123 Donaldson & Clavijo, 1994).

124 Round scad are very frequently reported as stomach contents of pelagic and demersal
125 piscivores (Matheson, Huntsman & Manooch, 1986; Naughton, Saloman & Vaught, 1986), and
126 are often the most abundant species on FADs (Rountree, 1990), wrecks (Lindquist & Pietrafesa,
127 1989), and natural live bottoms (Parker, Chester & Nelson, 1994; Kendall, Bauer & Jeffrey,
128 2009; Burge et al., 2012) in portions of the South Atlantic Bight. Round scad schooling

129 behaviors have been described (Rountree, 1989, 1990; Lindquist & Pietrafesa, 1989; Rountree &
130 Sedberry, 1991). Observed abundances of round scad at FADs and other structures accentuates
131 this species' affinity for physical objects which can include larger fishes and elasmobranchs.

132 In the Gulf of Mexico, Fuller and Parsons (2019) report aggregations of round scad and
133 another carangid, Atlantic bumper (*Chloroscombrus chrysurus* (Linnaeus, 1766)), associating
134 with blacktip sharks (*Carcharhinus limbatus* (Müller and Henle, 1839)), spinner sharks
135 (*Carcharhinus brevipinna* (Müller and Henle, 1839)), and blacknose sharks (*Carcharhinus*
136 *acronotus* (Poey, 1860)). In situ observations with sand tiger sharks have not been previously
137 reported prior to the current study, but photographs document associations between round scad
138 and sand tiger sharks on North Carolina reefs (this study) and wrecks
139 (<https://ncaquariums.wildbook.org/gallery.jsp>), and are mentioned by Fuller and Parsons (2019).

140 Many different examples of commensal and mutualistic heterospecific fish associations have
141 been described. Reasons for heterospecific association behavior are typically categorized as
142 cleaner-client interactions, protection from predation, increased foraging opportunities, and
143 hydrodynamic or transportation efficiencies. For example, the mackerel scad *Decapterus*
144 *macarellus* (Cuvier in Cuvier and Valenciennes, 1833), an ecologically similar and sympatric
145 relative of round scad *D. punctatus*, associated with goliath grouper *Epinephelus itajara*
146 (Lichtenstein, 1822) to reduce their vulnerability to predation by the horse-eye jack *Caranx latus*
147 Agassiz in Spix and Agassiz, 1831. Mackerel scad were described as forming a dense
148 aggregation around the grouper while under threat by jacks, and the school of scad moved with
149 the grouper as one unit. The authors conclude that this behavior was likely advantageous for
150 mackerel scad by reducing their risk of predation by a mesopredator (jack) that was itself
151 potential prey for the grouper (Macieira et al., 2010).

152 *Mesopredators (MPs)*

153 Mesopredators are traditionally defined as intermediate trophic level predators relative to a
154 smaller group of apex carnivores that occupy top trophic positions within a food web.

155 Assignment of any given species to its role as a mesopredator is, of course, context dependent, as

156 the removal of apex predators affects the trophic position of others within the web (reviewed in

157 Prugh et al., 2009). From a practical perspective, mesopredator species richness is typically

158 higher under apex predator control (Terborgh, 2015), although the relative effects of

159 competition, facilitation, and indirect effects are difficult to assess broadly. There are also

160 instances in which mesopredator abundance and species richness are controlled by their lower

161 taxonomic level prey. In such scenarios, commonly referred to as wasp-waisted ecosystems, a

162 lack of species diversity at the primary consumer level (i.e. planktivorous fish) allows several or

163 even a single species to control trophic exchange from primary producers to higher level

164 consumers (Cury et al., 2000). Therefore, the abundance and diversity of mesopredators is

165 dependent on their ability to capture this essential primary consumer group. In many wasp-waist

166 ecosystems, mesopredator predation success is conventionally controlled by the abundance of the

167 essential primary consumer which is influenced by seasonal environmental factors (e.g. El

168 Niño/La Niña) and predator abundance (Bakun, 2006). However, it is also important to consider

169 other factors that might influence predation success and ultimately mesopredator abundance and

170 diversity. Primary consumer association with higher level apex predators and similar anti-

171 predation behaviors could reduce predation success for mesopredators and be an overlooked

172 factor that contributes to the control of mesopredators in wasp-waisted ecosystems.

173 A diverse assemblage of pelagic and demersal piscivorous mesopredatory fishes inhabit hard

174 bottom habitats of the South Atlantic Bight (Chester et al., 1984; Sedberry & Van Dolah, 1984;

175 Kendall, Bauer & Jeffrey, 2009; Burge et al., 2012; Burge, O'Brien & jon-newbie, 2020).
176 Pelagic mesopredators include medium to large-sized jacks (greater amberjack *Seriola dumerili*,
177 almaco jack *Seriola rivoliana* Valenciennes in Cuvier and Valenciennes, 1833, blue runner
178 *Caranx crysos*, crevalle jack *Caranx hippos* (Linnaeus, 1766)) and scombrids (little tunny
179 *Euthynnus alletteratus* (Rafinesque, 1810), and Atlantic bonito *Sarda sarda* (Bloch, 1793)). All
180 are reported to prey on round scad or similar small fishes (Manooch III & Haimovici, 1983;
181 Saloman & Naughton, 1984; Manooch III, Mason & Nelson, 1985; Campo et al., 2006; Sley et
182 al., 2009; Fletcher, Batjakas & Pierce, 2013). Interestingly, some demersal mesopredators alter
183 their behavior in the presence of pelagic mesopredators feeding on round scad that blurs the line
184 between pelagic and demersal (Auster et al., 2009, 2013).

185 *Underwater video*

186 Underwater videography using stationary cameras is an efficacious method to conduct in-situ
187 marine observations, including surveying marine fish assemblages for species richness and
188 abundance, and behavioral observations (reviewed in Mallet & Pelletier, 2014). Video
189 observations are non-extractive and can be depth and time independent, relative to in person (i.e.
190 SCUBA diver) observations.

191 Potential bias associated with SCUBA surveys can be introduced as fish react to the presence
192 of divers, sometimes for long periods post-survey (Emslie et al., 2018), and this effect has been
193 observed to be species specific (Cole, 1994; Kulbicki, 1998; Burge et al., 2012; Lindfield et al.,
194 2014). For example, sand tiger sharks display increased respiration and movement in the
195 presence of SCUBA divers (Barker, Peddemors & Williamson, 2011), providing evidence that
196 underwater videography may be a better alternative to observe the behavior of this species. Once
197 recorded, videos can be reviewed multiple times to optimize the amount of data collected from a

198 single event, and can potentially increase recognition of behaviors that would otherwise be
199 difficult to assess during SCUBA diving observations.

200 In this study, we examined association behavior between sand tiger sharks (STs), round scad
201 (RS), and scad mesopredators (MPs) using a unique, long-term underwater video installation
202 sited on a hard bottom reef off the coast of Cape Fear, North Carolina. Based on video
203 observations collected to assess the fish species assemblage (E Burge, 2020, unpublished data)
204 and in situ observations by Burge and others, we repeatedly noticed the unusual association
205 between STs and RS. Consequently, we hypothesized that association behaviors between round
206 scad and sand tigers were more frequent in the presence of pelagic mesopredators than in their
207 absence because the presence of mesopredators represents a potential predation threat for round
208 scad. Strength of the association behavior was believed to be a response to mesopredators that
209 reflects round scad vulnerability. We also suspect that aggregations of round scad may be
210 mutually beneficial to sand tiger sharks by providing camouflage and increasing predation
211 opportunities on mesopredators. Direct, visual observations of wild behavior of sand tiger sharks
212 are very limited (but see Smith, Scarr & Scarpaci, 2010; Barker, Peddemors & Williamson,
213 2011), and this species is currently IUCN Red listed as Vulnerable, making conservation and
214 research efforts necessary for protection of this species. Investigating this association behavior
215 may be insightful for a deeper understanding of predation strategies of sand tiger sharks,
216 protective behaviors of a common prey species, and contribute knowledge of trophic dynamics
217 on hard bottom reefs in the South Atlantic Bight.

218

219 **Materials & Methods**

220

221 *Study site and infrastructure*

222 Video collected in this project are from SharkCam, an underwater, live-streaming camera,
223 publicly-viewable from <https://explore.org/livecams/oceans/shark-cam> (Explore.org, Los
224 Angeles, CA). The camera is sited beneath Frying Pan Tower (33°29'N, 77°35'W) which is
225 located at the seaward edge of Frying Pan Shoals, approximately 60 km off the coast of Cape
226 Fear, North Carolina. Frying Pan Shoals lies near the northern edge of a marine biogeographic
227 transition zone between a tropical and warm-temperate zone to the south (Caribbean
228 Biogeographic Province) and cold-temperate and polar waters to the north (Western Atlantic
229 Biogeographic Province) (Floeter et al., 2008; Toonen et al., 2016). The camera is attached to a
230 horizontal support at the base of Frying Pan Tower in about 15 m of water and is surrounded by
231 an expansive area of natural hard bottom (Riggs et al., 1996; NC Division of Marine Fisheries,
232 2020) and anthropogenic debris
233 (https://www.youtube.com/playlist?list=PLK1g13VpyT6oYUJL7U3hRPt2U5L_mcKL). To
234 date, videos from SharkCam have been used to identify 116 temperate and tropical marine fish
235 species (November 2014–February 2020) (Burge, O'Brien & jon-newbie, 2020).

236 View Into The Blue® (Boulder, CO) cameras with CleanSweep™ hardware were used for all
237 footage captured (<https://www.viewintotheblue.com/>). The cameras used (six during the span of
238 this project) featured HD 720p (November 2014–July 2016 footage) or HD 1080p (after October
239 2016) video resolution, 360° pan-tilt-zoom that rotated on a pre-determined schedule, or with
240 manual remote control, and a field of view of 62° × 37° (horizontal × vertical). Automatic white
241 balance (color control) was enabled in April 2017 to more closely approximate surface light for
242 color correction. Power is provided by a solar installation atop Frying Pan Tower and data
243 transmission used a line-of-sight radio to shore (Burge, O'Brien & jon-newbie, 2020)

244 *Video analysis*

245 SharkCam video files containing sand tiger sharks *Carcharias taurus* (STs, n = 216) were
246 extracted from a larger video database of all fish species occurrences gathered from non-
247 consecutive, 20-min clips (n=1024) analyzed as part of a larger community analysis project (E
248 Burge 2020, unpublished data). Video files were recorded during local daylight hours between
249 November 2014 and January 2019. All videos containing STs were re-analyzed for the
250 simultaneous presence of round scad *Decapterus punctatus* (RS) and STs within the frame of the
251 camera view. Duration of the STs on screen (seconds) was recorded to obtain average
252 observation time.

253 Videos containing simultaneous co-occurrences of both species were assigned a descriptive
254 category of the association behavior between RS and STs using the following categories: no
255 visible interaction (NVI), loosely associated (LA), and tightly associated (TA) (Figure 1). No
256 visible association was defined as both species moving independently of each other or in
257 opposing directions and with their heads oriented in different directions. Loosely associated
258 aggregations were defined as both species moving in a similar direction, their heads oriented in a
259 similar direction, and RS maintaining an estimated distance of five body lengths or more from
260 STs and other school members. Tightly associated aggregations were defined as both species
261 moving as one entity, their heads oriented in the same direction, and RS maintaining less than
262 five estimated body lengths from STs and other school members. These behaviors represent a
263 spectrum of association that we hypothesize correlates with the vulnerability of RS to predation
264 in response to the presence of pelagic mesopredators (MPs); NVI representing the least
265 vulnerable and TA representing the most vulnerable. Video files with multiple sightings of STs
266 were treated as independent occurrences if shark observations were separated by 10-min or

267 greater. Multiple association observations within a 10-min interval were assigned a descriptive
268 category that best described the general association behavior of the recurring individuals. We
269 were not able to individually identify observed STs, however, we have no reason to believe that
270 this association behavior was limited to individual sharks given the multi-year duration over
271 which videos were collected.

272 In order to assess the behaviorally-mediated responses of RS to the presence of
273 mesopredators (MPs), we documented the presence, species composition, and relative abundance
274 of six selected MPs within all 20-min video segments that also contained STs and RS.
275 Mesopredators considered to be mediators of RS and STs association behavior were selected
276 based on similarities in their predation style and size, and observations from SharkCam that
277 documented or suggested feeding on RS. Almaco jack (*Seriola rivoliana*, AJ), Atlantic bonito
278 (*Sarda sarda*, AB), blue runner (*Caranx crysos*, BR), crevalle jack (*Caranx hippos*, CJ), greater
279 amberjack (*Seriola dumerili*, GA), and little tunny (*Euthynnus alletteratus*, LT) were used as
280 representatives of pelagic mesopredators (individual body size approximately 0.5 m–1.5 m)
281 because of their highly active feeding behavior, including predation attempts documented on
282 SharkCam (data not shown), literature confirming their predation on RS or a similar species
283 (Manooch III & Haimovici, 1983; Saloman & Naughton, 1984; Manooch III, Mason & Nelson,
284 1985; Campo et al., 2006; Sley et al., 2009; Fletcher, Batjakas & Pierce, 2013), and their co-
285 occurrence in videos that suggest facilitated, or even cooperative, hunting (Auster et al., 2013,
286 2019).

287 *Data analysis*

288 Hierarchical cluster analysis using Bray-Curtis similarity was used to illustrate the strength of
289 co-occurrences between STs, RS, and each species of mesopredator in all recorded instances of

290 sharks (n=216). Presence or absence data within 20-min video segments for all analyzed videos
291 were square root transformed, Bray-Curtis similarity values were calculated, and a hierarchical
292 cluster analysis was performed with statistical significance tested with 1000 simulation
293 permutations by Simprof ($\alpha=0.05$) in Primer-E 6.x (Plymouth Marine Laboratory UK).

294 Pearson's chi-squared test (χ^2) was used to further investigate whether the frequency of
295 association behaviors between STs and RS were more commonly observed than expected if each
296 category of association had an equal chance of occurring (33%). Equal likelihoods of each
297 association category occurring were assumed to represent a condition in which RS did not
298 benefit from a close physical association with STs. Pearson's χ^2 was also used to test the
299 frequency of association behaviors in the presence of one or more species of mesopredator. The
300 behavior categories were used to represent a continuum of association that reflected the relative
301 vulnerability of RS to pelagic MPs.

302 Multinomial logistic regression ('multinom', R version 3.5.1) was used to calculate the log-
303 odds of association behavior (i.e. LA and TA behaviors) in the presence or absence of one or
304 more species of mesopredator. This analysis expanded on the results from the χ^2 analysis, which
305 only compared the frequency of association behavior in the presence of MPs, by making
306 predictions of the frequency of association behavior in the presence and absence of MPs. Odds
307 ratios were exponentially transformed to obtain percentage values. We hypothesized that MPs
308 facilitated association behavior between STs and RS, therefore presence or absence data of MPs
309 was used as the independent variable and the association behavior was the dependent variable for
310 this analysis. We expected to see the log-odds of association behavior increase in the presence of
311 mesopredators, therefore the association category that represented the least degree of round scad
312 vulnerability, NVI, was used as the baseline in the analysis.

313

314 **Results**

315 Of the 1024, 20-min intervals of video analyzed, 216 clips (21%) contained one or more
316 occurrences of STs and were used for hierarchical cluster analysis with Bray-Curtis similarity.
317 Among clips that contained STs, 186 (86%) included simultaneous observations of RS and STs
318 and were used in multinomial logistic regression. Of the videos that contained STs and RS, 159
319 (85%) contained one or more species of MPs and were used in the Pearson's χ^2 . Average
320 observation time of STs and RS association behavior within clips was 36 ± 37.5 s (mean \pm SD),
321 range 3–254 s, median 26 s.

322 *Visual observations*

323 In the absence of MPs and STs, RS were commonly observed swimming in unpolarized,
324 distributed schools as they foraged for plankton. Foraging and plankton feeding were inferred
325 from a commonly seen behavior where individuals flex their bodies slightly upward while
326 simultaneously opening the mouth (head-tipping), often with slight lateral adjustments,
327 presumably to ingest individual plankters (https://youtu.be/7_i8hoQXeAU).

328 When STs were not observed and MPs were actively foraging on RS, RS responded by
329 forming denser schools (i.e. reducing nearest neighbor distance), and often retreated to the sea
330 floor or associated with the structure of Frying Pan Tower (<https://youtu.be/IesLMb9OStw>,
331 <https://youtu.be/CTwih5UYaqw>, <https://www.youtube.com/watch?v=CIFLIu2FVfA>).

332 During LA behavior with STs, RS exhibited unpolarized schooling behaviors, but maintained
333 proximity and speed with the STs (https://www.youtube.com/watch?v=_CIqWVUprmU).

334 During TA aggregation behavior, RS decreased distance to nearest neighbor and STs, and moved
335 with the STs as one entity (<https://youtu.be/P37lg7iiDJo>).

336 Distinct transitions between behavioral categories were rarely observed, and the few
337 observed transitions captured the movement from LA aggregations to TA aggregations. During
338 these observations, RS displayed an immediate response (less than one second) to MPs. In some
339 of these occurrences, RS can be described as “pulsating” around the shark, as they transitioned
340 constantly between a LA and TA state (https://youtu.be/9WuEyByf_Pw, [https://youtu.be/1Ss-
341 AvAMkVg](https://youtu.be/1Ss-AvAMkVg)).

342 *Predation attempts*

343 Regardless of the species involved, apparently successful piscivorous predation seen on
344 SharkCam is exceedingly rare (E Burge, 2020, unpublished data). During data collection from
345 1024, 20-min intervals of video (>340 h), we recorded all likely successful fish-on-fish predation
346 events and noted the species involved. Only a small number of observations of STs predation
347 attempts on MPs or other species were made (see examples <https://youtu.be/cfGFAq1cQtl>,
348 <https://youtu.be/PlIHZr-ioeo>, <https://youtu.be/i5wO7ILbbd8>, <https://youtu.be/P37lg7iiDJo>), and
349 these were always on prey species much larger than round scad (LT, gag *Mycteroperca*
350 *microlepis* (Goode and Bean, 1879), red drum *Sciaenops ocellatus* (Linnaeus, 1766)).
351 Additionally, STs were only observed making predation attempts on other fishes when tightly
352 associated with RS. During these rare phenomena, sand tiger sharks made quick lunges toward
353 approaching fishes that appeared oblivious to the presence of the STs, presumably due to shrouds
354 of RS tightly associated with the shark. Although STs were never observed capturing prey during
355 these attempts, it appeared that schools of RS concealed the presence of STs and attracted scad
356 predators to the STs.

357 *Descriptive frequencies*

358 Sand tiger sharks are fall-winter-spring visitors seen most frequently during cool months
359 (21.3% overall frequency of occurrence, n=1024; Figure 2). Round scad are ubiquitous during
360 cool months and appear to depart in May–June and September–October (64.8% overall
361 frequency of occurrence, n=1024; Figure 2), but are most frequently seen during periods of STs
362 residency. The combinatorial frequency of occurrence for these two species (co-occurrence) was
363 13.8% within the 1024 videos. Additionally, the frequency of videos (of 1024) that contained
364 STs, RS, and one or more species of up to six different MPs was 16.3% (combinatorial
365 frequency of occurrence for 3+ species).

366 However, in videos selected because they contained STs (100% frequency of occurrence,
367 n=216), RS were much more likely to be seen (86.1% frequency of occurrence), and the
368 likelihood of this co-occurrence was strongly clustered with the presence of one or more MPs
369 species (83.7%, combinatorial frequency of occurrence for 3+ species). Of the six species of
370 MPs selected for this study, four species (almaco jack, blue runner, little tunny, and Atlantic
371 bonito) were more frequently observed within the data set of only STs videos (n=216) than the
372 SharkCam occurrence data set (n=1024) (Table 1).

373 *Association behavior*

374 Sand tiger sharks and RS clustered together the strongest (92.5%), while MPs had lower
375 similarities (Figure 3). Among MPs, GA was significantly clustered with RS and STs and had
376 the highest similarity value of all MPs (63.4%). Almaco jack (54.2% similarity) and BR (37.9%
377 similarity) were also significantly clustered with STs, RS, and GA, while LT, CJ, and AB were
378 not significantly clustered within the group.

379 Analysis of the 186 videos containing co-occurrence of STs and RS resulted in 40
380 observations of NVI, 58 observations of LA behavior, and 88 observations of TA behavior

381 without regard to the presence or absence of MPs (Figure 4). In the presence of MPs the
382 frequency of LA and TA behaviors increased. NVI was least frequently observed (n=33), and TA
383 behavior was most frequently observed (n=79). There was a significant difference in the
384 observed occurrences of behavioral categories compared to their expected frequencies, assuming
385 equal likelihoods of occurrence in the presence of MPs (Pearson's $\chi^2 = 20.981$; df 2; $p < 0.000$).
386 Compared to no visible association, the log-odds of round scad being loosely associated with
387 STs was 82.9% greater, and tightly associated behavior was 196% greater in the presence of
388 mesopredators, but this result was not statistically significant ($p > 0.05$), likely due to the number
389 of NVI behaviors seen even when MPs were present.

390

391 **Discussion**

392 Based on SharkCam underwater video observations conducted over more than 5 years and
393 representing over 340 hours of underwater footage, we demonstrate that round scad (RS) are
394 significantly more likely to be associated with sand tiger sharks (STs) in the presence of potential
395 scad mesopredators (MPs), than in their absence. This example of a behaviorally-mediated
396 indirect interaction (BMII) has important implications for trophic energy transfer on hard
397 bottoms in the SAB.

398 Round scad are the most abundant pelagic, planktivorous fish species observed on these hard
399 bottom habitats (Lindquist & Pietrafesa, 1989; Rountree, 1990; Burge et al., 2012), and high
400 densities of RS are especially apparent on mid-shelf live-bottoms of the SAB in winter (Hales
401 Jr., 1987). Under these circumstances, MPs are likely dependent on RS as a primary prey
402 resource, especially in cooler months, therefore, the ecosystem as a whole depends on round scad
403 for the transfer of energy up the food chain. Given this, it is important to investigate round scad

404 association behavior with sand tiger sharks and be aware that this interaction may have effects on
405 trophic transfer and mesopredator control. We have no reason to believe this STs and RS
406 association behavior is unique to the hard bottom habitat off Cape Fear, North Carolina,
407 therefore describing this behavior and its motivation aids in understanding trophic interactions
408 and prey strategies that influence predation success for pelagic predators. While the possibility of
409 benefit to STs in the form of increased predation opportunities remains an open question,
410 available observations provide evidence that STs use this association to perform an
411 undocumented predation strategy. The concealment provided to STs by RS and the attraction of
412 MPs to the shark suggest that this association behavior facilitates the feeding behavior of sand
413 tiger sharks.

414 Underwater videography has often been used to survey marine fish assemblages for diversity
415 and abundance in many locations (reviewed in Mallet & Pelletier, 2014). For example, video has
416 revealed that hard bottom habitat near Frying Pan Tower supports a diverse assemblage of both
417 temperate and tropical reef fish species that fluctuates seasonally (Burge et al., 2012; Burge,
418 O'Brien & jon-newbie, 2020). With few exceptions, underwater video to assess multispecies
419 behavior that includes large and highly mobile predators, is much more limited (but see Davis et
420 al., 1999; Dunbrack & Zielinski, 2003; Barker, Peddemors & Williamson, 2011; Bond et al.,
421 2012; Kanno et al., 2019; Brown et al., 2020), despite evidence that video may be an
422 advantageous survey method (McCauley et al., 2012).

423 Admittedly, the limited field of view of SharkCam served as a constraint to fully observe
424 behavior between STs, RS, and MPs because interactions occurred rapidly and in three-
425 dimensional space. In this study, occurrences of MPs outside the perspective of SharkCam
426 undoubtedly influenced events captured on camera, and this is likely responsible for many of the

427 observations of loosely associated (LA) and tightly associated (TA) behaviors that occurred in
428 the absence of MPs (STs+RS-MPs, $n=27$). One or more species of selected MPs occurred in
429 approximately 84% of videos containing STs and RS (Table 1). Additionally, many other species
430 of potential scad mesopredators are also present at Frying Pan Tower, including a diverse
431 assemblage of demersal piscivores, and other pelagic species not designated as MPs in analyses
432 (Table S1). Recent work by Brown et al. (2020), also on sand tiger sharks in North Carolina, has
433 revealed that the presence of the sharks alters short-term reef fish community richness on
434 shipwrecks, with the prevalence of pelagic mesopredators elevated, and those of demersal
435 mesopredators depressed. They suggest that these differences in richness may be behaviorally-
436 mediated responses attributed to mesopredator optimization of foraging strategy, with sharks as a
437 threat to or competitor with pelagic mesopredators. Given this, it is likely that there are few
438 circumstances when aggregations of round scad are not exposed to potential predators. The
439 inclusion of STs+RS-MPs videos in the multinomial logistic regression likely resulted in the lack
440 of statistical significance ($p>0.05$), despite the relatively large increases in the odds of
441 association behavior as association strength increased (82.9% for LA and 196% for TA). This
442 pattern is supported by the results of the chi-square analysis that show the frequency of
443 occurrence of association behavior increased with association strength ($p<0.00$, Figure 4).

444 In similar research analyzing predator influence on prey behavior, Seghers (1974)
445 hypothesized that guppies formed schools because they were always exposed to predation
446 threats. Constant exposure to predators provides a strong explanation for why round scad are
447 observed forming associations with sand tiger sharks when designated MPs are not seen on
448 SharkCam. While observations of round scad association with sand tiger sharks in the absence of
449 MPs observations may be a result of sampling bias, it suggests that aggregation behavior is

450 driven by perceived predation risk assessed by the scad, and further suggests near constant
451 exposure to mesopredators. Experimental manipulation of mesopredators, their prey, and apex
452 predator presence have tested perceived predation risk to prey and mesopredators in marine (del
453 Mar Palacios et al. 2016) and terrestrial (Gordon et al., 2015) settings—one commonality that
454 emerges is that the presence of an apex predator alleviates perceived risk to prey by providing a
455 “refuge effect” associated with behavioral changes in prey.

456 Behavioral descriptions of RS and STs association were created to classify three distinct
457 levels of association based on preliminary observations. Inclusion of a continuous, quantitative
458 variable to measure aggregation strength would have increased the accuracy of identifying round
459 scad responses to mesopredators but was not necessary given how distinct existing behavioral
460 categories were. Nearest neighbor distance is a structural measurement used for fish aggregations
461 to calculate the positional preference of individual fish within an aggregation based on the
462 positions and movements of adjacent fish (Parrish, Viscido & Grunbaum, 2002). Evidence
463 supports that synchronization and group coordination are mediated by an individual’s
464 interactions with nearest group members (Ballerini et al., 2008; Niizato & Gunji, 2011). We
465 visually estimated nearest neighbor distance of round scad to other aggregation members and to
466 sand tiger sharks to incorporate a measure of aggregation structure into our behavioral
467 descriptions to reduce observer bias. Conventionally, model simulations have been effectively
468 used to understand the mechanisms that influence strength, response to stimulus, and
469 coordination of fish schools (Huth & Wissel, 1992; Parrish, Viscido & Grunbaum, 2002).

470 In-situ experiments analyzing fish aggregation dynamics are far less common given the
471 difficulty to track individual fish. High resolution acoustic sonar (DIDSON) has recently become
472 a reliable alternative to conduct in-situ analysis of fish schooling behavior and has the capability

473 of monitoring the movement of individual fish (Moursund, Carlson & Peters, 2003; Boswell,
474 Wilson & Cowan, 2008; Rieucou et al., 2016). Auster et al. (2013) used DIDSON techniques to
475 effectively analyze prey distribution during predator-prey interactions similar to those observed
476 in this study on hard-bottoms in the SAB. DIDSON analysis would support more quantitative
477 data on the structure of associations between RS and STs, but was not necessary to understand
478 interactions between RS and MPs and would introduce additional cost for support and
479 maintenance.

480 Observations of RS becoming more aggregated in response to perceived predation threats are
481 consistent with prior literature (Rountree & Sedberry, 1991; Auster et al., 2009, 2013).
482 Reduction in nearest neighbor distance (i.e. increase in polarity) facilitates more efficient
483 communication between school members which enhance group synchrony and coordination
484 (Rieucou et al., 2015).

485 Sharks were always the nucleus of associations in our study and proximity to sharks we
486 hypothesized served as an additive predation defense against mesopredators. Although we
487 focused on association as protective for round scad with sharks, it is important to consider other
488 potential explanations for this behavior. Fuller and Parsons (2019) report observations of
489 association between RS and several species of sharks. Their potential explanations for this
490 behavior include protection from mesopredator predation, optomotor responses (Shaw & Tucker,
491 1965), and scatophagy on shark fecal clouds. We did not document the frequency of round scad
492 feeding during associations or observe foraging on fecal clouds, but round scad foraging for
493 plankton was common during observations. As fish forage, especially pelagic planktivores like
494 round scad, they become more vulnerable to predation; therefore, future studies should consider
495 foraging benefits and how associations with sharks reduced vulnerability during foraging. It is

496 also important to continue to explore the possible benefit of this association to sand tiger sharks
497 to fully understand how this association influences trophic interactions.

498

499 **Conclusions**

500 Based on in situ and underwater video observations from SharkCam, we hypothesized that
501 association behaviors between round scad and sand tigers were more frequent in the presence of
502 pelagic mesopredators than in their absence because the presence of mesopredators represents a
503 potential predation threat for round scad. Scad were shown to be significantly more likely to be
504 tightly associated with sand tiger sharks in the presence of mesopredators, compared to in their
505 absence. This example of a behaviorally mediated indirect interaction suggests that presence of
506 an apex predator alleviates perceived risk to prey from mesopredators. These results illuminate a
507 previously undescribed interaction with important consequences for trophic transfer and
508 mesopredator control on hard bottom habitats, and support the usage of long-term underwater
509 camera installations for addressing questions in marine ecology.

Table 1 (on next page)

Occurrence of sand tiger sharks, round scad, and six mesopredator species in SharkCam videos.

Videos analyzed (n=1024, 20-min clips) were collected November 2014-January 2019.

Frequency of occurrence data are for all videos, and those known to contain STs (n=216, 20-min clips). The frequency of STs + RS in all clips was 0.138.

1

2

Common Name	Species	Acronym	Videos containing	Frequency of occurrence	
				In STs clips (n=216)	In all clips (n=1024)
Sand Tiger Shark	<i>Carcharias taurus</i>	STs	216	1.000	0.213
Round Scad	<i>Decapterus punctatus</i>	RS	186	0.861	0.648
Greater Amberjack	<i>Seriola dumerili</i>	GA	106	0.491	0.580
Almaco Jack	<i>Seriola rivoliana</i>	AJ	89	0.412	0.351
Blue Runner	<i>Caranx crysos</i>	BR	61	0.282	0.210
Crevalle Jack	<i>Caranx hippos</i>	CJ	25	0.116	0.164
Little Tunny	<i>Euthynnus alletteratus</i>	LT	34	0.157	0.078
Atlantic Bonito	<i>Sarda sarda</i>	AB	9	0.042	0.015
			Frequency containing STs + RS + ≥1 MPs =	0.837	0.163

Figure 1

Sand tiger sharks and round scad in association behaviors.

(A) No visible interaction (NVI). Image from 18 April 2017, 12:43 EDT, (B) Loosely associated (LA). Image from 11 November 2019, 16:05 EST, (C) Tightly associated (TA). Image from 13 March 2018, 14:14 EDT. Image credits: Erin Burge/Explore.org.

Figure 2

Frequency of occurrence of sand tiger sharks and round scad indicate the seasonality of their presence at Frying Pan Tower.

Seasonality of sand tiger sharks (STs) and round scad (RS) are represented by frequency of occurrence data (solid line, STs; dashed line, RS) from SharkCam videos (n=1024, 20 min clips) from November 2014–January 2019. Sea surface temperatures (SST) are plotted as 2016 mean daily water temperature ($^{\circ}\text{C}$) \pm SD (open circles), 2003–2008 long term mean monthly SST (black circles on gray line), and 2003–2008 minimum and maximum monthly SST (gray stippled lines) at Frying Pan Tower (data from NOAA NBDC Station 41013 (LLNR 815)–Frying Pan Shoals, NC).

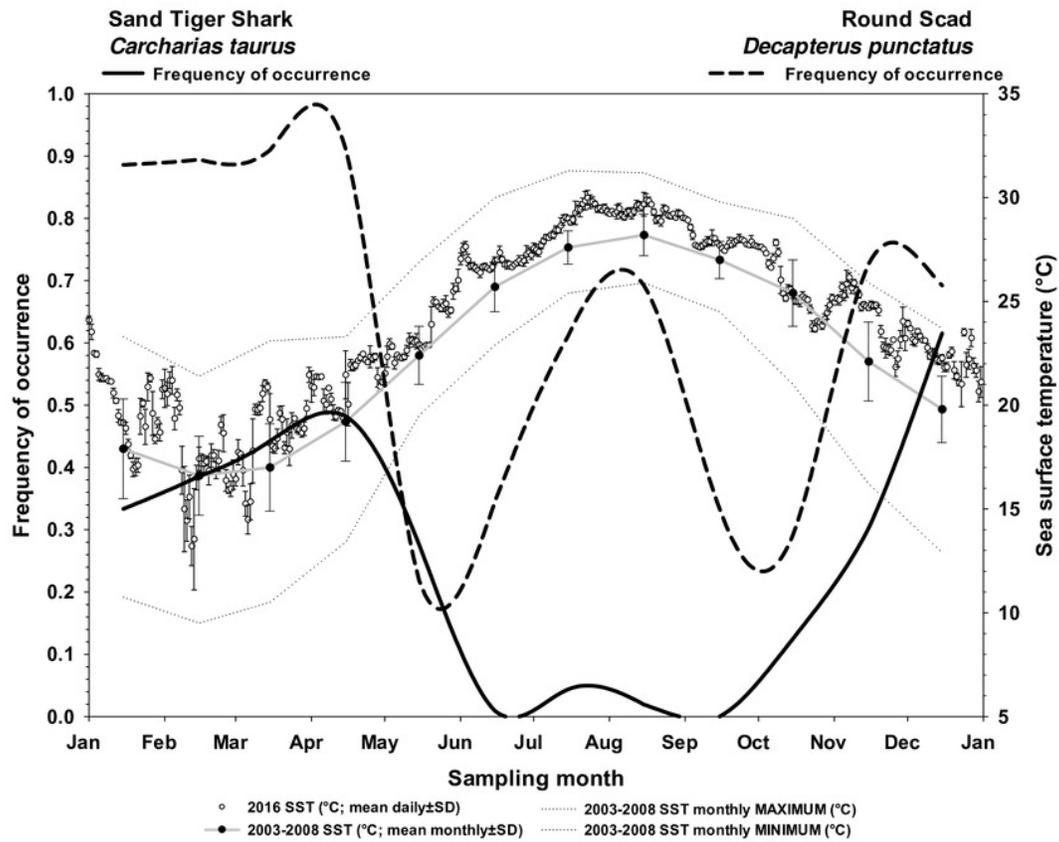

Figure 3

Cluster analysis of Bray-Curtis similarity to illustrate associations between sand tiger sharks (STs), round scad (RS), and individual mesopredator species (MPs).

See Table 1 for mesopredator species acronyms. STs and RS cluster strongly (92.5% similarity), while MPs have lower similarities. Clusters containing red-dashed branches are significant (Simprof, $\alpha = 0.05$).

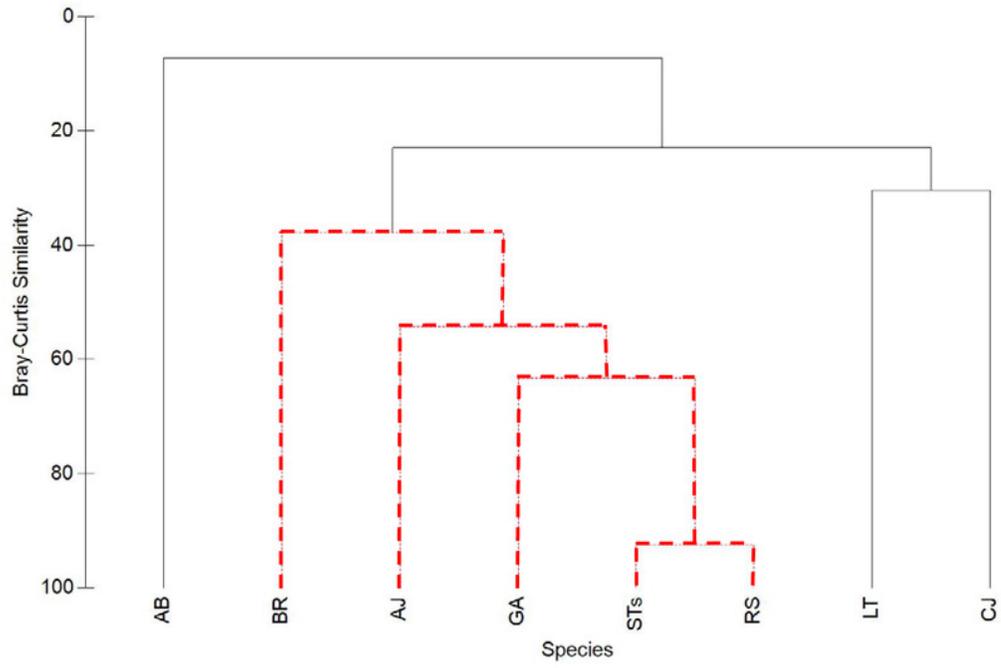

Figure 4

Association behavior counts between sand tiger sharks (STs) and round scad (RS).

(A) without and with the presence of mesopredators (MPs), and observed and expected frequencies (B) of association behaviors in video clips collected from SharkCam (n=186, 20-min clips). Tightly associated behavior between STs and RS occurred significantly more often than expected (Pearson's $\chi^2 = 20.981$ (df 2), $p < 0.000$) in the presence of MPs.
