Previous research has highlighted that Emotional Intelligence (EI) is related to an array of positive interpersonal behaviours, including greater human empathy. Nonetheless, although animals are an integral part of our lives, there is still a lack of clarity regarding the way in which EI relates to empathy towards animals. The aim of this study was to investigate the relationship between EI and empathy towards humans and animals. We used the Trait-Meta Mood Scale to assess EI, the Interpersonal Reactivity Index to assess empathy for humans, and the Animal Empathy Scale to assess empathy for animals. Our findings revealed a positive relationship between empathy for humans and animals. The results also supported the idea that EI is positively related to empathy for humans, while the relationship between EI and empathy for animals was dependent on whether or not the participants had experience with pets. In addition, multiple regression analysis showed that the variables that best predicted empathy for animals were having a pet (or not), age, gender and human empathic concern. Finally, the relationship between human empathic concern and empathy for animals was stronger in participants who had pets. These findings provide a better understanding of the mechanisms underlying empathic behaviour and suggest that empathy for humans and animals can be influenced by different factors. Limitations and future lines of research are discussed.

42 **Abstract**

43 Previous research has highlighted that Emotional Intelligence (EI) is related to an array of positive

44 interpersonal behaviours, including greater human empathy. Nonetheless, although animals are an

45 integral part of our lives, there is still a lack of clarity regarding the way in which EI relates to

46 empathy towards animals. The aim of this study was to investigate the relationship between EI and

47 empathy towards humans and animals. We used the Trait-Meta Mood Scale to assess EI, the

48 Interpersonal Reactivity Index to assess empathy for humans, and the Animal Empathy Scale to

49 assess empathy for animals. Our findings revealed a positive relationship between empathy for

50 humans and animals. The results also supported the idea that EI is positively related to empathy

51 for humans, while the relationship between EI and empathy for animals was dependent on whether

52 or not the participants had experience with pets. In addition, multiple regression analysis showed

53 that the variables that best predicted empathy for animals were having a pet (or not), age, gender

54 and human empathic concern. Finally, the relationship between human empathic concern and

55 empathy for animals was stronger in participants who had pets. These findings provide a better

56 understanding of the mechanisms underlying empathic behaviour and suggest that empathy for

57 humans and animals can be influenced by different factors. Limitations and future lines of research

75

76

77   Nowadays it is generally accepted that the intelligent use of emotions has a positive impact
78   on the psychological adaptation of the individual to their environment (Mayer & Salovey, 1997;
79   Salovey et al., 1999; Salovey et al., 1995), providing them with a better chance of success (Mayer
80   et al., 2008). Based on this perspective, research conducted within the field of emotional
81   intelligence (EI) has made a significant contribution to knowledge and evidence regarding the
82   positive effects of emotions. In particular, research in recent decades indicates that an array of
83   positive outcomes can be attributed to higher levels of EI, including improved well-being and
84   mental health (Martins et al., 2010: İnce et al., 2019), academic or professional performance (Costa
85   & Faria, 2015; O'Boyle et al., 2011), prosocial behaviour and satisfaction with social networks
86   (Ciarrochi et al., 2000; Mayer et al., 1999), lower levels of clinical symptomatology (Bastian et
87   al., 2005; Megías et al., 2018a) and aggressive or disruptive behaviour (Brackett et al., 2004; Davis
88   & Humphrey, 2012; Lopes et al., 2011; Megías et al., 2018b).

89   In this regard, research has also been devoted towards exploring the relationship between
90   EI and empathetic behaviours, namely the positive effects of EI on empathy for other humans.
91   Nonetheless, to date no research has addressed the specific relationship between EI and empathy
92   for animals, in spite of the fact that animals play a very important role in our society, and are an
93   integral part of culture, leisure, well-being, work, and politics. In fact, public opinion would
94   suggest that people who show sensitivity to nonhuman species have greater emotional abilities.
95   However, the analysis of well-known cases, such as activists who violate human rights to save
96   animals or even Hitler and his Nazi companions who were animal lovers (Paton, 1993),
97   demonstrate that empathy for animals may not always relate to empathy for humans. This study
98   presents a preliminary attempt to extend knowledge on the relationship between EI and empathy
99   towards humans and animals.

100   *EI and empathy towards humans*

101   EI can be conceptualized as the capacity to process emotional information and comprises
102   the "ability to perceive accurately, appraise, and express emotion; the ability to access and/or
103   generate feelings when they facilitate thought; the ability to understand emotion and emotional

104   knowledge; and the ability to regulate emotions to promote emotional and intellectual growth"

105   (Mayer & Salovey, 1997, p. 10). Thus, both intrapersonal and interpersonal emotional abilities are

106   considered to fall under this category of mental abilities (Mayer & Salovey, 1997).

107   Particular interest has been paid to the link between EI and empathy, since the latter

108   constitutes a relevant factor in social interaction and prosocial behaviour (Gilet et al., 2013).

109   Empathy, as a multidimensional construct that comprises emotional, cognitive and motivational

110   components (Baron-Cohen & Wheelwright, 2004; Cuff, Brown, Taylor, & Howat, 2014), is based

111   on the abilities to recognize, understand, and share the feelings of others (Davis, 1980; de Waal,

112   2008; Preston & de Waal, 2002). More specifically, cognitive empathy reflects the way in which

113   we understand others, their experiences and emotions, emotional empathy involves the emotional

114   response to the experience of others and actually sharing that particular emotional state with the

115   other (Smith, 2006), which often generates an empathic concern, understood as compassion or

116   motivational empathy, which leads a person to take action to relieve the suffering of others

117   (Eisenberg & Miller, 1987; Pfattheicher et al., 2015).

118   Considering that perceiving and understanding emotion in others and emotional

119   awareness are abilities involved in EI, it might be reasonable to suppose that there is a positive

120   relationship between EI and empathy (Schutte et al., 2001). In fact, there are parallels between

121   some of the features of EI and empathy. Petrides et al. (2004) found evidence to suggest that the

122   trait EI models comprise affect-related functioning such as emotional awareness, empathy and

123   relationship skills. According to Mayer and Salovey (1997), an individual with optimum EI can

124   better perceive, understand, and manage their own emotions, and are more likely to be skilled at

125   generalizing these abilities of perceiving, understanding, and managing to the emotions of others.

126   Some authors have even argued that empathy is a result of EI, since the ability to reason about

127   emotions in ourselves and others will have an impact on the accurate interpretation and

128   management of social interactions and emotional experiences (Mayer et al., 2008).

129   Various authors have delved further into this relationship and confirmed that individuals

130   with higher EI are also more empathetic towards other people (Fitness & Curtis, 2005; Mayer et

131   al., 1999; Schutte et al., 2001, 2005). This positive relationship has been established when

132   evaluating EI using different types of measures, including self-report (Fitness & Curtis, 2005;

133   Salovey et al., 2002; Schutte et al., 2001) and performance tests (Ciarrochi et al., 2000; Mayer et

134   al., 1999). In particular, some studies found that attention to emotions correlated positively with

135   the empathy dimensions of empathic involvement and personal distress (Aguilar-Luzón &

136   Augusto, 2009; Extremera & Fernández-Berrocal, 2004). A higher level of emotional clarity and

137   repair has also been positively associated with perspective taking and negatively associated with

138   personal distress, both of which are aspects of empathic behaviour (Aguilar-Luzón & Augusto,

139   2009; Extremera & Fernández-Berrocal, 2004; Ramos et al., 2007).

140   Although the relationship between EI and human empathy has been explored in the

141   literature, rather less attention has been paid to the issue of how EI relates to empathy directed

142   towards other entities, including empathy for animals. Given that empathy is related to the socio-

143   emotional abilities to recognize, understand and share the feelings of others, and that understanding

144   and being aware of the emotional signs in animals (with more or less phylogenetic proximity to

145   humans) can pose particular challenges since this is quite distinct from human interactions, the

146   relationship between EI and empathy towards animals could be quite different from the one

147   established with humans.

148   *Relationship between empathy directed to humans and to animals*

149   Over the past few decades, public opinion has shifted from the traditional conceptions of

150   animals as objects to be used by humans to a broader ethical perspective of care and compassion

151   towards them. In fact, the public attitudes to animals related to increasing sensitivity and concern

152   about animal use have developed in parallel with the stronger beliefs about the ability of animals

153   to experience pain and suffering, along with their cognitive abilities and their sentience (Cornish,

154   Wilson, Raubenheimer, & McGreevy, 2018). This progressive change in society's attitudes

155   towards animals is most likely to be based on the increasing proximity with animals in our daily

156   life (e.g., pets) and on the countless contexts in which housed animals such as zoos, aquariums,

157   museums, sanctuaries, shelters, nature centres and others offer opportunities to have educational

158   experiences with animals and nature (Young, Khalil, & Wharton, 2018).

159   Within the broader research area on the nature of empathy, the earliest studies exploring

160   the relationship between human individuals and other animals emerged and, in particular, these

161   works demonstrated that humans are able to feel empathy for animals (e.g., Emauz et al., 2016;

162   Paul, 2000). Moreover, empathy towards animals seem to have originated in a similar way as that

163   shown towards other humans (Ascione, 1992; Kohl, 2012; Ruckert, 2016). In his precursory

164   research, Paul (2000) elaborated on the previous empathy definition put forward by Eisenberg
165   (1995) and specified that empathy towards animals entailed a vicarious emotional response to the
166   emotions or states of animals, and the cognitive understanding of their thoughts or feelings. For
167   Drane (2009) empathy is the ability to feel what others are feeling, regardless of whether this
168   comes from a direct relationship between humans or animals. Jorge Ritchman (cited in García,
169   2014) also extrapolated empathy towards our relationship with animals, considering this to be
170   fundamental to our coexistence, since it allows us to perceive the damage that we can cause to
171   other species, feel their suffering, or avoid it (García, 2014). More recently, a metanalytic review
172   on empathy for animals defined empathy as a simulated emotional state that relies on the ability
173   to perceive, understand and care about the experiences or perspectives of another person or animal
174   (Young et al., 2018). Therefore, empathy towards animals comprises the same three abilities as
175   empathy towards humans – affective empathy, cognitive empathy, and empathic concern (Cuff et
176   al., 2014). Affective empathy is the ability to sense or physically experience the emotions of
177   another (Cuff et al., 2014). For instance, when an individual observes an animal in a state of
178   suffering, he/she may experience distress as if they were responding to the same stimulus (Eres,
179   Decety, Louis, & Molenberghs, 2015). Cognitive empathy is the ability to understand the
180   experiences of others by recognizing and imagining their reality (Cuff et al., 2014), and might
181   support (or not) our affective empathy. For instance, it supports our affective empathy when we
182   believe the animal is suffering because we recognized that it is physically injured; or it does not
183   provide such support, when, for instance, we understand that an animal is isolated due to their
184   specific biological characteristics and it is not a sign of depression. Empathic concern, on the other
185   hand, can motivate a person to take action and relieve the suffering of the animal (Eisenberg &
186   Miller, 1987; Pfattheicher et al., 2015), and in that case, an individual would help an animal that
187   is injured or trapped.

188   Some authors consider that empathy for animals has a strong heritable component and can
189   evolve differently depending on the particular species of animals (Bradshaw & Paul, 2010).
190   Research suggests that the development of empathic behaviour is due to its adaptative components,
191   which would enable pro-social behaviour and inhibit aggression. Another possibility explored by
192   some investigators is that the process of nurturing (e.g., providing food and shelter, care-giving)
193   infants and babies would have had an impact on the development of the empathic behaviours of

194   humans, considering that the ability to empathetically respond to the distress shown by children is

195   a crucial component of the emotional nurturance process (de Waal, 2008).

196   Moreover, the literature also indicates that there is a positive relationship between the

197   empathy directed to humans and animals, although this is not of a high magnitude (Ellingsen et

198   al., 2010; Emauz et al., 2016; Paul, 2000). Other studies have also found that concerns about animal

199   suffering are associated with higher levels of empathy for humans (Ascione, 1992; Komorosky &

200   O`Neal, 2015). However, when exploring whether individuals particularly characterized by high

201   levels of affection towards animals have high levels of affection towards humans, the results are

202   contradictory (Paul, 2005). For instance, a very high level of affection for animals can be related

203   to a displacement of affection from people to pets (Veevers, 1985). Therefore, it is not always

204   evident that in order to be empathetic towards animals the individual should also be empathetic

205   towards humans or vice versa. These findings suggest that empathy for humans and for animals

206   — whilst many times related — are probably not the same unitary construct, representing different

207   psychological concepts or, at least, separately influenced by specific factors (Paul, 2000; Paul,

208   2005). Perhaps the possibility that both types of empathy have shared and non-shared components

209   or because they act under the influence of specific moderator mechanisms could explain why

210   differences are often observed in the empathic responses shown towards human individuals and

211   other animals (Paul, 2000).

212   *EI and empathy towards animals*

213   To date, there are no reports regarding the relationship between EI and empathy directed

214   to animals of any kind, except humans. One could argue that EI is related to several positive

215   emotional outcomes such as empathy for humans (Fitness & Curtis, 2005; Mayer et al., 1999;

216   Schutte et al., 2001, 2005) and that a similar association is likely to be found for empathy towards

217   animals. However, as previously described, the literature on empathy for animals has presented

218   mixed results, that is, supporting the association between attitudinal and prosocial behaviours

219   towards animals and towards people (Ellingsen et al., 2010; Emauz et al., 2016; Komorosky &

220   O`Neal, 2015) or indicating that those behaviours can be independent (Paul, 2005). Moreover, the

221   dynamics of the relationships between individuals are far more complex than those established

222   with animals. One possibility is that the ability to understand and manage emotions based on

223   human interactions might prove to be insufficient to perceive and understand the emotions of

224   animals, which hinders the capacity of humans to empathise with them. Therefore, it is possible

225   that for there to be an association between EI and empathy for animals, the influence of other

226   variables — such as the person's current experience with animals — could be critical.   In this

227   regard, EI can be associated with empathy for humans and other positive human-oriented outcomes

228   but might not necessarily be correlated with animal-oriented constructs, for instance, advocating

229   for animal rights, being compassionate towards animals in distress, or taking a stance against the

230   use of animals for scientific purposes.

231   *Gender differences in EI and empathy*

232   Previous studies in the literature have revealed gender differences in EI, and in empathy

233   for humans and animals. Whilst in general, women score higher than men on the main factors that

234   constitute EI, this difference appears to depend on the type of instrument used. Specifically, when

235   a performance-based instrument is used, women score higher than men on all dimensions;

236   however, when using a self-report instrument, particularly the TMMS (Salovey et al., 1995),

237   women tend to score higher than men on the dimension of attention to emotions, and lower on the

238   dimensions of emotional clarity and repair (Cabello & Fernández-Berrocal, 2015; Fernández-

239   Berrocal & Extremera, 2008; Joseph & Newman, 2010; Navarro-Bravo et al., 2019). Further,

240   previous studies indicate that women, compared with men, tend to exhibit higher levels of empathy

241   for both humans and animals (Angantyr et al., 2011; Klein & Hodges, 2001; Paul, 2000; Serpell,

242   2004).

243   *Aim*

244   The main objective of this research was to investigate the relationship between EI and

245   empathy for humans and animals. We conducted a detailed study through the analysis of several

246   EI and empathy sub-dimensions. In addition, we examined the possible effect of previous

247   experience with animals on these relationships. Based on the findings of the previous literature,

248   we also explored possible gender-related differences in the scores of EI and empathy. We

249   hypothesized that (1) there is a positive relationship between EI and empathy for animals; (2) there

250   is a positive relationship between empathy for humans and empathy for animals; (3) with respect

251   to the relationship between EI and empathy for animals, we conducted an exploratory analysis

252   since it is not possible to formulate a clear hypothesis given the mixed findings reported in the

253   previous literature; and finally, (4) we proposed that the relationships between EI, human empathy

254 and empathy for animals may depend on the degree of proximity between the individual and
255 animals (operationalized according to whether they have pets or not).

256 **Methods**

257 *Participants*

258   The sample was composed of four hundred and seventy-one adult volunteers (34.4% male).
259 They were recruited through advertisements at the University of Malaga, social networks, and
260 online platforms. The age of the participants ranged from 18 to 65 years with a mean of 26.15
261 years (SD = 10.10). Two hundred and fifty-eight of the participants were pet owners. All
262 participants were informed that confidentiality and anonymity of the collected data would be
263 assured, and they were treated in accordance with the Helsinki declaration (World Medical
264 Association, 2008). The study was approved by The Research Ethics Committee of the University
265 of Málaga as part of the project PSI2017-84170-R (IRB approval number CEUMA 14-2019-H).

266 *Procedure and instruments*

267   Online questionnaires were completed by the participants through the LimeSurvey
268 platform (http://limesurvey.org). The respondents accessed the questionnaires via an email link
269 sent by the authors. An informed consent form was included in the survey, and the participants
270 were assured of confidentiality and anonymity. To avoid missing data, the questionnaires were set
271 up so that blank responses were not allowed. For each participant, this entire process took
272 approximately 20 minutes to complete.

273 A description of each scale is detailed below:

274   Trait-Meta Mood Scale (TMMS; Salovey et al., 1995). The TMMS is a 24-item self-report
275 scale widely used to assess EI. The questionnaire includes three sub-dimension scores: attention
276 to emotions (awareness of our emotions, the ability to recognize our feelings and know what they
277 mean), emotional clarity (ability to know, understand, distinguish and understand how emotions
278 evolve, ability to integrate emotions in our thinking), and emotional repair (ability to regulate and
279 control positive and negative emotions). Responses are given on a 5-point Likert type scale ranging
280 from 1 ("Disagree strongly") to 5 ("Agree strongly"). We used the Spanish version of the scale
281 (Fernández-Berrocal et al., 2004). In our study, the scale showed good internal consistency
282 (Cronbach's alpha values of the sub-dimensions ranged between .85 and .91).

283   Interpersonal Reactivity Index (IRI; Davis, 1983) is a 28-item self-report scale used to
284   measure empathy. This scale is composed of four sub-dimensions: perspective taking (ability of
285   subjects to adopt other people's point of view), empathic concern (tendency of subjects to
286   experience feelings of compassion and concern towards others), personal distress (tendency of
287   subjects to experience feelings of anxiety and discomfort when witnessing the negative
288   experiences of others) and fantasy (tendency of subjects to identify with fictional characters from
289   books and movies). Each item uses a 5-point Likert scale ranging from 1 ("Does not describe me
290   at all") to 5 ("Describes me very well"). We used the Spanish version of the scale (Escrivá et al.,
291   2004). In our study, the scale showed adequate internal consistency (Cronbach's alpha value of
292   the total score was .79 and for the sub-dimensions this ranged between .66 and .76).

293   Animal Empathy Scale (AES; Paul, 2000) is a 22-item self-report scale used to measure
294   empathy for animals through the assessment of the individual's feelings about animals and their
295   treatment. The scale comprises items that enquire about both empathic relationships (e.g., "It
296   makes me sad to see an animal on its own in a cage"; "It upsets me when I see helpless old
297   animals") and non-empathic relationships (e.g., "Dogs sometimes whine and whimper for no real
298   reason"; "Sometimes I am amazed how upset people get when an old pets dies"). Responses are
299   scored by a 9-point Likert scale ranging from 1 ("Disagree strongly") to 9 ("Agree strongly"). We
300   used the Spanish version of the scale in our study (La Torre Gómez, 2017). In our study, the scale
301   showed adequate internal consistency (Cronbach's alpha value of the total score was .87).

302   *Data analysis*

303   First, descriptive statistics were computed to examine the characteristics of the scores of
304   the measures employed, both for the total sample and divided by gender. Second, gender
305   differences were contrasted using t-tests. Third, differences according to pet and non-pet
306   ownership were examined by t-tests. Fourth, Pearson's correlations were conducted to explore
307   associations between the study variables. Fifth, in order to verify if the association between
308   empathy for animals and the variables of empathy for humans and EI are influenced by having
309   pets, additional Pearson´s corelation analyses were carried out by dividing the sample into pet
310   owners and non-pet owners. Besides, using Fisher's Z-test, we tested if there were significant
311   differences between the human empathy and EI correlation and the animal empathy and EI
312   correlation, in the latter case for both the total sample and the sample divided according to pet
313   ownership status. Sixth, we conducted hierarchical multiple regression analyses in order to identify

314   the study variables most strongly associated with empathy for animals. Pet ownership, gender and

315   age were entered at Step 1, the three EI sub-dimensions were entered at Step 2, and the four human

316   empathy sub-dimensions were entered at Step 3. Finally, we explored the possible moderating

317   effect of pet ownership on the significant relationships observed in the previous regression

318   analysis. Descriptive statistics, t-tests, Pearson's correlations, Fisher's Z-test and regression

319   analyses were carried out using SPSS® version 24.0 (IBM Corporation, Armonk NY, USA) and

320   FZT computator (http://psych.unl.edu/psycrs/statpage/regression.html). SPSS PROCESS macro

321   2.16, Model 1 (Hayes, 2013) was used for the moderation analysis.

322

323   **Results**

324   Table 1 displays the descriptive statistics and gender differences for the variables included

325   in the study. We observed that women, in comparison with men, scored higher on the attention to

326   emotions sub-dimension of EI ($p < .01$), in the perspective-taking, empathic concern, fantasy, and

327   personal distress sub-dimensions of human empathy ($p < .01$) and on the scale of empathy for

328   animals ($p < .01$). T-tests comparing pet owners and non-pet owners only revealed significant

329   differences on the scale of empathy for animals, where pet owners obtained a higher score ($p <$

330   .01; see Table 1 for more details).

331   - Insert Table 1 -

332   Pearson´s correlation analysis including the total sample (see Table 2) confirmed that

333   scores on the attention to emotions sub-dimension of EI were positively related to all sub-

334   dimensions of human empathy (ps $< .05$); the emotional clarity sub-dimension was negatively

335   related to personal distress, and positively related to fantasy and perspective-taking (ps $< .05$); and

336   the emotional repair sub-dimension was positively related to perspective-taking and fantasy, and

337   negatively related to personal distress (ps $< .05$). Regarding empathy for animals, the results

338   revealed a positive relationship between the levels of empathy for animals and human empathy for

339   the sub-dimensions of perspective-taking, fantasy and empathic concern. Moreover, higher levels

340   of empathy for animals were related to higher EI, but only for the sub-dimension of attention to

341   emotions.

342   - Insert Table 2 -

343   Pearson´s corelation analyses conducted by dividing the sample into pet owners and non-
344   pet owners (see Table 3) revealed a positive relationship between empathy for animals and human
345   empathy for the sub-dimensions of perspective-taking and empathic concern in both samples.
346   Moreover, a positive relationship was also revealed between empathy for animals and the human
347   empathy sub-dimension of fantasy, but only for the sample of pet owners. With respect to the
348   relationship between empathy for animals and EI, in the sample of non-pet owners, empathy for
349   animals was not related to any of the sub-dimensions of EI. However, in the sample of pet owners,
350   the results showed that higher levels of empathy for animals were related to higher EI for the sub-
351   dimensions of attention to emotions and repair.

352   - Insert Table 3 -

353   When specific comparisons between correlations were made using Fisher's z-test, it was
354   found that the EI sub-dimension of attention to emotions showed a significantly stronger positive
355   relationship with the human empathy sub-dimensions of perspective-taking ($Z = 3.07, p < .01$) and
356   empathic concern ($Z = 3.59, p < .01$) than with empathy for animals. Emotional clarity showed a
357   significantly stronger correlation with the human empathy sub-dimensions of perspective-taking
358   ($Z = 2.46, p < .05$), fantasy ($Z = 2.14, p < .05$), and personal distress ($Z = 3.46, p < .01$) than with
359   empathy for animals. Finally, emotional repair showed a significantly stronger relationship with
360   the human empathy sub-dimensions of fantasy ($Z = 2.67, p < .01$) and personal distress ($Z = 4.82$,
361    $p < .01$) than with empathy for animals. Finally, we did not find significant differences between
362   the animal empathy and EI correlation when the sample was divided into pet owners and non-pet
363   owners ($Z = 0.76$, NS, for attention to emotions, $Z = 0.22$, NS, for emotional clarity NS, $Z = 1.29$,
364   NS, for emotional repair).

365   In order to examine the study variables that can best predict empathy for animals, a
366   hierarchical regression analysis was carried out with empathy for animals as criterion, and pet
367   ownership, gender and age (Step 1), sub-dimensions of EI (Step 2), and sub-dimensions of human
368   empathy (Step 3) as predictors. The significant predictors of empathy for animals included in the
369   first step were pet ownership, gender and age; in the second step these were pet ownership, gender,
370   and the attention and repair sub-dimensions of EI, and in the third step these were pet ownership,
371   age, gender and the empathic concern sub-dimension of human empathy (see Table 4 for details).
372   The final model accounted for 16.1 percent of the variance in empathy for animals.

373   - Insert Table 4 -

374   Finally, moderation analyses were conducted with EI and the human empathy sub-
375   dimensions that were significant predictors of empathy for animals. The results revealed that
376   having a pet had a moderating effect on the relationship between empathic concern and empathy
377   for animals, indicating that this relationship was stronger in participants who had pets (see Figure
378   1; interaction effect = -10.41, 95% CI [-18.38, -2.44]). The rest of the sub-dimensions did not show
379   a significant moderation effect.

380   - Insert Figure 1 -

381   **Discussion**

382   Previous studies in the literature have shown that EI is related to positive aspects, such as
383   better mental health, greater prosocial behaviours, and greater human empathy (Ciarrochi et al.,
384   2000; Fitness & Curtis, 2005; Martins et al., 2010). However, to date, the relationship between EI
385   and empathy for animals has not been studied, despite the fact that animals are an increasingly
386   important part of our society and everyday living. The present study attempted to delve more
387   deeply into the relationship between EI and empathy for humans and for animals. More in-depth
388   knowledge about these factors could help us to understand the differences that exist between
389   personal emotional capacities and sensitivity to animals.

390   First, our study revealed that women, compared with men, showed a higher score on the EI
391   sub-dimension of attention to emotions. This result is consistent with the previous literature and
392   supports the hypothesis that women appear to have a greater ability to recognise feelings and know
393   their meaning (Cabello & Fernández-Berrocal, 2015; Fernández-Berrocal & Extremera, 2008). We
394   also found that women, compared with men, obtained higher scores on all the human empathy sub-
395   dimensions. Empirical studies have indicated that women have a greater capacity than men for
396   understanding the thoughts and feelings of others (Klein & Hodges, 2001; Schieman & Van
397   Gundy, 2000). Finally, we observed that women scored significantly higher than men on empathy
398   for animals. This finding is in accord with various studies showing that women tend to show a
399   more positive attitudes towards animals (Furnham et al., 2003, Paul, 2000; Serpell, 2004). With
400   regard to differences according to pet ownership, we found that pet owners showed higher scores
401   on empathy for animals than those participants who did not have a pet. These results are in accord

402   with those reported in the previous literature, showing that familiarity with animals increases

403   empathy for them (Paul, 2000).

404   With respect to the Hypotheses 1 and 2, our results were consistent with most of the

405   findings in the literature (Ellingsen et al., 2010; Extremera & Fernández-Berrocal, 2004; Findlay

406   et al., 2006; Fitness & Curtis, 2005; Juntilla et al., 2006). Regarding Hypothesis 1, the results

407   confirmed that, in general, an adequate level of EI was related to higher levels of human empathy

408   (Fitness & Curtis, 2005; Mayer et al., 1999; Schutte et al., 2001, 2005). However, it must be noted

409   that an excess of empathic involvement (i.e., higher scores on personal distress) could hinder the

410   ability to engage in emotionally intelligent behaviours (Extremera & Fernández-Berrocal, 2004).

411   This latter assumption could explain the observation that levels of personal distress were

412   negatively related to emotional clarity and repair. With regard to Hypothesis 2, we found a positive

413   relationship between most of the human empathy sub-dimensions and empathy for animals.

414   Specifically, this study found that the emotional aspect of human empathy (the sub-dimension of

415   empathic concern) was the best predictor of empathy for animals. This finding is also in accord

416   with previous research (Ellingsen et al., 2010; Emauz et al., 2016; Paul, 2000) and suggests that

417   those individuals with higher scores on human empathy also have a more welfare-oriented attitude

418   towards animals. Whilst several theories could explain this result, in general, research indicates

419   that someone who is empathetic, that is, capable of adopting the point of view of animals, and

420   exhibits concern about them is likely to have similar feelings towards people (Eisenberg et al.,

421   1992; Lockwood, 1983; Messent, 1983; Rossbach & Wilson, 1992).

422   To address Hypothesis 3, we analyzed the relationship between EI and empathy for

423   animals. Analysis of the total sample revealed that higher levels of empathy for animals were only

424   positively related to the sub-dimension of attention to emotions. However, when we introduced

425   EI, together with human empathy, as a predictor of empathy for animals, only the relationship with

426   the empathic concern sub-dimension remained significant.

427   Finally, in order to verify if these relationships depended on the degree of familiarity (in

428   terms of pet ownership) that the person has with animals (Hypothesis 4), we conducted further

429   analyses by dividing the participants into two samples, that is, pet owners and non-pet owners.

430   Two main results were found. First, for the sample of pet owners, the results revealed a positive

431   correlation between the sub-dimensions of attention to emotions and repair with empathy for

432   animals, whilst analysis of the sample of non-pet owners did not yield any significant relationship
433   between EI and empathy for animals. Second, the relationship between empathic concern and
434   empathy for animals was significantly stronger for those participants who had pets compared with
435   those without pets. These findings suggest that interaction with animals can influence the
436   relationship between EI, human empathy, and empathy for animals. Moreover, these results could
437   also reflect a potential bidirectional effect of the association established between empathy for
438   animals and pet ownership; individuals who have/had a pet report greater empathy for animals,
439   but also people with greater empathy for animals are also more likely to have pets and enjoy or
440   value their company.

441   In summary, the current findings do not support the notion that people who have better
442   emotional abilities are more empathetic towards animals. Our results instead appear to support the
443   idea that the proficiency for understanding and managing emotions is developed on the basis of
444   human interactions and such emotional abilities are insufficient to perceive and understand the
445   emotional signs of animals and consequently empathise with them. Direct interaction with animals
446   would thus be needed to improve these emotional abilities. To the best of our knowledge, this is
447   the first time that the relationship between EI and empathy for animals has been investigated.
448   Although EI has been linked to better interpersonal social relationships, prosocial behaviour, and
449   greater empathy for humans (Brackett et al., 2004; Gilet et al., 2013, Komorosky & O`Neal, 2015;
450   Lopes et al., 2011), the results of our study indicate that EI may not be a determining factor in
451   empathy for animals, or at least suggests that the mechanisms underlying both types of empathy
452   are influenced by different factors (Paul, 2000, 2005).

453   The present study provides a first step towards a better understanding of the relationships
454   between empathy for humans and animals. However, it is important to consider that the
455   methodology employed was correlational and thus future lines of investigation should conduct
456   experimental studies to determine causality between variables. Advances in the study of this
457   relationship could have practical implications such as the promotion of interventions aimed at
458   increasing human empathy levels through animal-assisted therapy. This type of therapy could be
459   helpful for decreasing antisocial behaviours and aggressiveness among peers and, in addition,
460   could promote appropriate attitudes and respect for animal welfare.

461   As limitations of the research, it is important to note that our sample was not gender
462   matched, with a greater number of women than men (34.4% were men). Moreover, given that
463   previous literature has shown that the ability to empathize is influenced and reinforced by
464   similarity, age, gender, factors related to theory of mind or personality traits (de Waal, 2008;
465   Kavanagh et al., 2013), future studies should explore possible differences in the empathy and EI
466   relationship as a function of these factors. It is also important to note that, due to the correlational-
467   transversal design of this research, further exploration of the potential bidirectionality effects
468   among the variables could not be tested in this study (e.g., empathy for animals and pet ownership).

469   Future research studies should aim to replicate these results in other countries, since there
470   are cultural differences that could modify people's empathic values with respect to animals (Young
471   et al., 2018). In addition, the degree of proximity to animals has only been operationalized in terms
472   of pet ownership, thus excluding people who have other types of close relationships with animals,
473   such as farmers, or people that work in other, similar professions. Therefore, future research should
474   explore the various types of relationships that humans can have with animals. Finally, the
475   questionnaires used in this research were self-report instruments, the responses of which are
476   susceptible to possible response and introspective biases. In a similar vein, the reliability of the
477   IRI questionnaire was not very high (Cronbach's alpha ranged between .66 and .76). In future
478   investigations it might therefore be useful to work with behavioural and performance measures in
479   order to address these issues.

480
481   **Conclusion**

482   The main objective of the current research was to clarify the relationship between EI and
483   empathy for humans and animals in order to have a better understanding of the factors that underlie
484   empathic behaviour towards animals and its relationship with empathy for humans. Our results
485   revealed the existence of a positive relationship between both types of empathy (humans and
486   animals). A positive relationship between EI and empathy for humans was also observed.
487   However, these relationships were dependent on the participants' experience with animals.
488   Overall, these results support previous literature regarding the positive relationship between EI
489   and empathy for humans, but the mixed findings observed between EI and empathy for animals
490   suggests a greater complexity in the relationships between these constructs, perhaps indicating that
491   both types of empathy can be guided by different factors or represent different psychological

492 constructs. Although preliminary conclusions can be drawn from these results, further
493 investigation is necessary in order to replicate these findings and better understand the common
494 and distinctive process involved in empathy for humans and animals, and their association with EI
495 abilities.

Figure 1

Figure 1. Effect of empathic concern on empathy for animals, moderated by pet ownership.

Values on the y-axis represent the levels of empathy for animals. Values on the x-axis represent levels of empathic concern where high and low were specified at - 1 SD (low) and + 1 SD (high) of the centered means.
