#### Abstract

Many agricultural regions in arid and semiarid climate zone need to deal with increased soil salinity. Legumes are classified as salt-sensitive crops. A field experiment was performed to examine the application of phosphorus ( P ) fertilizer source and rate on growth, chlorophylls and carotenoid content, DNA and RNA content and ion accumulation in common bean (Phaseolus vulgaris L.) cultivated under salinity stress. An experimental design was split-plot with three replicates. The main plots included two $P$ sources, namely single superphosphate (SP) and urea phosphate (UP). The sub-plots covered four P rates, i.e., $0.0,17.5,35.0$, and $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. All applied P fertilization rates, in both forms, increased plant height, leaf area, dry weight of shoots and roots per plant, and total dry weight (TDW) in $t$ $\mathrm{ha}^{-1}$. The highest accumulation of $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Mg}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ was determined in the shoot and root of common bean, while 35 kg of P per ha ${ }^{-1}$ was used compared to the other levels of P fertilizer. The highest P rate ( $52.5 \mathrm{~kg} \mathrm{ha}^{-1}$ ) resulted in a significant reduction in $\mathrm{Na}^{+}$in shoot and root of common bean. The response curve of TDW $\left(\mathrm{tha}{ }^{-1}\right)$ to different rates of $\mathrm{P}\left(\mathrm{kg} \mathrm{ha}^{-1}\right)$ proved that the quadratic model fit better than the linear model for both $P$ sources. Under SP, the expected TDW was $1.675 \mathrm{t} \mathrm{ha}^{-1}$ if P was applied at $51.5 \mathrm{~kg} \mathrm{ha}^{-1}$, while under UP, the maximum expected TDW was $1.875 \mathrm{t} \mathrm{ha}^{-1}$ if P was supplied at $42.5 \mathrm{~kg} \mathrm{ha}^{-1}$. In conclusion, the $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ could be considered the best effective P level imposed. The application of P fertilizer as urea phosphate is generally more effective than single superphosphate in enhancing plant growth and alleviating common bean plants against salinity stress.

## INTRODUCTION

From an agricultural point of view, the beginning of the $21^{\text {st }}$ century is characterized by global warming, rainfall deficit, environmental deterioration, and increased soil and water salinization. Sustainable agriculture has to tackle two major issues: the rising human population and the decrease the area of land available for strategic crops' cultivation (Shahbaz \& Ashraf, 2013). It was estimated that $20 \%$ of total crop production worldwide and $33 \%$ of irrigated agricultural land in Egypt is under pressure of high salinity (Akladious \& Mohamed, 2018; Sofy, Elhawat \& Alshaal, 2020a). Besides, the salinized areas have been rising at a rate of $10 \%$ annually as a result of low rainfall, high surface evaporation, soil erosion, saline water irrigation, and extensive cultural practices. It is forecasted that by the year 2050 more than half of the arable area would be salinized (Jamil et al., 2011; Latif \& Mohamed, 2016; Mohamed, Akladious \& El-Beltagi, 2018).

The salinity stress in crops arise from the interactions between morphological, physiological, and biochemical processes affecting primarily germination stage and plant development and productivity through disturbed water and nutrient absorption, and enzyme activity (Abdelhamid et al., 2013; El-Mashad \& Mohamed, 2012; Mohamed \& Gomaa, 2012), DNA, RNA, and protein synthesis, and proper course of mitosis in cells (Javid et al., 2011). It was observed that as salinity $\left(\mathrm{NaCl}, \mathrm{CaCl}_{2}\right)$ increased, phosphate concentrations decreased in field-grown agricultural crops (Baker et al., 2013). Besides, Curtin, Steppuhn \& Selles (1993) reported that increased $\mathrm{Na}^{+}$and $\mathrm{Ca}^{2+}$ concentrations in the soil solution can contribute to raised ionic strength in the soil that can improve $P$ retention. The other elements and ions, including sodium $\left(\mathrm{Na}^{+}\right)$, chlorine $\left(\mathrm{Cl}^{-}\right)$, and boron (B) have particularly toxic effects on plants (Moustafa-Farag et al., 2020). The accumulation of sodium causes disturbances of cell membranes permeability, followed by osmotic stress and cell death (Sadak \& Abdelhamid, 2015).

In salinity conditions, ion toxicity results from the substitution of potassium ( $\mathrm{K}^{+}$) by $\mathrm{Na}^{+}$in biochemical reactions, and conformation disturbances in protein structure caused by $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$. Notably, $\mathrm{K}^{+}$serves as a cofactor for many enzymes, and $\mathrm{Na}^{+}$ions are not able to take over as $\mathrm{K}^{+}$. High concentration of $\mathrm{K}^{+}$is necessary to bind tRNA to ribosome in protein synthesis process (Rozov et al., 2019). $\mathrm{Na}^{+}$toxicity, followed by osmotic stress, contribute to metabolic dysfunction, resulting in oxidative stress (Orabi \& Abdelhamid, 2016). During the reproductive process, the salinity stress is the most destructive, concerning plant growth parameters.

Phosphorus ( P ) is mentioned among the most essential plant growth nutrients, since it is a crucial element of biological compounds, such as nucleic acids, nucleotides, phospholipids, and phospho-proteins. Phosphate compounds function inside plants as the "carbon currency" (Ahmed et al., 2018). Additional P application mitigates the reduction of plant growth caused by salinity (Wagdi et al., 2013). Under salt stress conditions, higher P dose caused a reduction in the $\mathrm{Na}^{+}$content in wheat (Wagdi et al., 2013), common bean (Bargaz et al., 2016), and radish (Oliveira et al., 2010). Therefore, the interaction between salinity and P nutrition is multifaceted, and it depends on species or
cultivar, stage of growth, salt composition and concentration, and the content of $P$ in soil (Fageria, Gheyi \& Moreira, 2011).

While several studies examined the impact of salinity or P deficiency on plant growth and nutrient uptake as independent growth-limiting factors, the knowledge on their combined action is still insufficient (Bargaz et al., 2016). Munns \& James (2003) determined that durum wheat absorbed the amount of P , exciding toxic level, in saline solution. Bargaz et al. (2016) investigated the grown response of common bean to three salinity levels ( $1.56,4.78$, and $8.83 \mathrm{dS} \mathrm{m}^{-1}$ ) and four $P$ rates ( $0,30,60$, and $90 \mathrm{~kg} \mathrm{ha}^{-1}$ ), and reported improved salt tolerance through adequate $P$ fertilization. $P$. vulgaris tolerance against salinity appears to be P-rate dependent. Abbas et al. (2018) found that low P (10 M) was more harmful to root and shoot growth of wheat than 100 mM NaCl , considering their discrepancies in salinity tolerance.

Common bean (Phaseolus vulgaris L.) is a grain food legume of economic importance in Egypt and many other countries (Broughton et al., 2003). Besides, P. vulgaris contributes about $50 \%$ of the world's grain legumes consumed, supplying high-quality protein in the human diet (Graham \& Vance, 2003). Unfortunately, the common bean is a salt-sensitive species, reacting in significant growth reduction at soil salinity less than 2 dS $\mathrm{m}^{-1}$ (Lauchli, 1984).

The hypothesis verified in this study was that with application of P in different P forms and various $P$ rates, common bean plants show increased growth parameters under $P$ deficiency and salinity stress. To verify this issue, a field experiment was performed, covering two forms of P : single superphosphate and urea phosphate, and four P fertilization rates: $0.0,17.5,35.0$, and $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. Growth parameters, chlorophyll content, nucleic acid content and mineral nutrients in common bean (Phaseolus vulgaris L.), cultivated in conditions of P deficiency and saline stress were examined.

## MATERIALS \& METHODS

## Experimental procedures

A field experiment was performed in moderate saline soil at a private farm, El Qanater El Khayreya, Qalyubia Governorate, Egypt ( $31^{\circ} 09^{\prime} 07^{\prime \prime} \mathrm{E} 30^{\circ} 11^{\prime} 35^{\prime \prime} \mathrm{N}$ ) during the 2019 season. daily temperatures ranged from 16.8 to $36.4^{\circ} \mathrm{C}$ with an average of $25.4 \pm 4.8^{\circ} \mathrm{C}$, while night-time temperatures $9.2 \pm 3.8^{\circ} \mathrm{C}$, with a minimum and a maximum of 2.2 and $18.2^{\circ} \mathrm{C}$. The average daily relative humidity was $68.7 \pm 10.3 \%$ and ranged between $36.6 \%$ and 83.7\%.

The common bean seeds (Phaseolus vulgaris L. cv. Nebraska) were selected, uniform and representative concerning size and color. The seeds were washed with distilled water, sterilized with $1.0 \%$ sodium hypochlorite solution for 2 min , washed with distilled water, and dried for 1 h at room temperature. Rhizobial inoculants have been used as peat slurry that contains $10^{7}$ Rhizobium per gram. The recommended seed rate for the common bean of $95 \mathrm{~kg} \mathrm{ha}^{-1}$ was used. Common bean seeds were sown in the field on the $10^{\text {th }}$ March 2019. Before the first irrigation, plants were thinned and one plant per hill was left. Before the cultivation, ammonium sulfate and potassium sulfate, at rates of $50 \mathrm{~kg} \mathrm{~N} \mathrm{ha}{ }^{-1}$ and $125 \mathrm{~kg} \mathrm{~K} \mathrm{ha}^{-1}$ were supplemented according to the recommendations for

the species. Before sowing, the physical and chemical soil characteristics were analysed with the methods described by Black et al. (1965) and Jackson (1973), and the results were presented in Table 1. Soil paste extract was used to determine electrical conductivity (EC). $\mathrm{EC}_{\mathrm{e}}$ was $5.21 \mathrm{dS} \mathrm{m}^{-1}$ that defines the soil as moderately saline (Hazelton \& Murphy, 2016). Traditionally, saline soils are classified as having an $\mathrm{EC}_{\mathrm{e}}$ value greater than $4 \mathrm{dS} \mathrm{m}^{-1}$. Salinity is an $E C_{e}$-based rating system for soil. When the $E C_{e}$ value varied between 4 and 8 dS $\mathrm{m}^{-1}$, the soil is classified as moderately saline. As a result, salt has an effect on the yields of many crops (Hazelton \& Murphy, 2016). Extractable soil phosphorus (P) content was 7.02 $\mathrm{mg} \mathrm{kg}^{-1}$ soil, which classed the soils as being low in P (Holford \& Cullis, 1985).

The experiment was conducted using a split-plot arrangement in a randomized complete block design with three replicates. P source was the first factor, assigned to the main plots, the rate of P was a second factor, allocated to the sub-plots (split-plots). P sources were as follows: (1) single superphosphate (SP), and (2) urea phosphate (UP). P rates were following: $0.0,17.5,35.0$, and $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. Each replicate included eight plots, i.e., two $P$ sources $\times$ four $P$ rates, eight treatments in total as it was shown in

(ET0) values. All other agricultural practices were performed according to the recommendations of the Ministry of Agriculture and Land Reclamation, Egypt for common bean and referred literature (Abdelhamid et al., 2013).

## Measurements

At 56 day after sowing (DAS), the following characteristics were analyzed on the samples consisted of ten plants per treatment: leaf area per plant, root dry weight per plant, shoot dry weight per plant, and total dry weight (DW) per plant. Total dry weight yield ( $\mathrm{tha}{ }^{-1}$ ) was determined by harvesting all plants from each experimental unit.

Chlorophylls and carotenoids were determined in the fresh leaves of 56 day-old plants. Pigments were extracted by homogenizing of 100 mg of fresh leaf tissue in pestle and mortar, in $80 \%$ acetone solution ( 10 mL ) followed by centrifugation for 20 min at $3,000 \mathrm{~g}$. The samples were storage at $4{ }^{\circ} \mathrm{C}$ for night, then optical density was measured at 480 nm for carotenoids, and 645 and 663 nm for chlorophyll a and b , respectively, following the method described by Arnon (1949).

DNA and RNA were extracted from leaves of common bean using a bench drill according to cetyltrimethylammonium bromide (CTAB) protocol (Doyle \& Doyle, 1990) and (Ferreira et al., 2019) for DNA and RNA extractions, respectively. The grinded plant tissues were dissolved inside the plastic bags $(20 \times 10 \times 0.01 \mathrm{~cm}$ of virgin, low-density polyethylene) at rotation of $2,500 \mathrm{rpm}$, until tissue is fully dissolved. The drill bit was cleaned with $70 \%$ alcohol for each sample change. The extraction buffer consisted of $2 \%$ CTAB, 100 mM , Tris-HCl, pH 8.0, 50 mM EDTA, pH 8.0; $1.4 \mathrm{M} \mathrm{NaCl}, 2 \%$ PVP-40; $1 \% \mathrm{Na}$ sulfite, all reagents were add before use. Two mL of extraction buffer were added to plastic bags containing 300 mg of leaf tissue and macerated with Biorema drill (Agdia, Inc., Elkhart, IN, USA).

Dried roots and shoots of 56 day-old plants were used for determining the ion accumulation. The samples were dried at $70^{\circ} \mathrm{C}$, in an electric oven, till constant weight was accessed, and finally ground. Nutrients concentration was determined in the shoot and root of common bean plants. Macronutrients namely, nitrogen ( N ), $\mathrm{P}, \mathrm{K}^{+}$, calcium $\left(\mathrm{Ca}^{2+}\right)$, and magnesium $\left(\mathrm{Mg}^{2+}\right)$, and micro-nutrients: iron $\left(\mathrm{Fe}^{3+}\right)$, manganese $\left(\mathrm{Mn}^{2+}\right)$, zinc $\left(\mathrm{Zn}^{2+}\right)$, and copper $\left(\mathrm{Cu}^{2+}\right)$, in addition to sodium $\left(\mathrm{Na}^{+}\right)$were determined. Total N was analyzed with the micro-Kjeldahl method. P was determined colorimetrically, after P extraction by sodium bicarbonate (Olsen, 1954), with stannous chloride-ammonium molybdate (King, 1951). $\mathrm{K}^{+}$was measured with a flame photometer (ELE Flame Photometer, Leighton Buzzard, UK). $\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Cu}^{2+}$, and $\mathrm{Na}^{+}$concentrations were determined by atomic absorption spectrophotometry (Chapman, 1965). $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}$, $\mathrm{Mg}^{2+}$, and $\mathrm{Na}^{+}$were expressed as gram per kilogram ( $\mathrm{g} \mathrm{kg}^{-1}$ ), while $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ were expressed as milligram per kilogram ( $\mathrm{mg} \mathrm{kg}^{-1}$ ).

## Statistical analysis of the data

The analysis of variance for a split-plot design was used to statistical elaboration of the experimental data (Gomez \& Gomez, 1984). Before the analysis, the data were tested for the homogeneity of error variances with the Levene test (Levene, 1961), and for normality
distribution with Shapiro and Wilk method (Shapiro \& Wilk, 1965). Statistically significant differences between means were determined at the $5 \%$ probability level ( $P \leq 0.05$ ) using Tukey's HSD (honestly significant difference) test. Correlation coefficients $r$ were calculated to determine the relationship between biomass dry weight yield and each of the mineral concentrations. The GenStat $17^{\text {th }}$ Edition (VSN International Ltd., Hemel Hempstead, UK) software was used for statistical analysis.

## RESULTS

To examine the effects of $P$ fertilization applied in the form of superphosphate and urea phosphate, and $P$ fertilization rate on common bean grown under salt-affected soil, thirty four traits were measured and presented below.

## Photosynthetic pigments of common bean

The interactive effect of phosphorus fertilization source and rate on total chlorophylls (TC) and carotenoids (Car) of common bean plants grown under salinity stress were shown in Table 2. Besides, the significance of the F test of analysis of variance was shown in Table 2. Urea Phosphate (UP) significantly increased TC and Car compared to superphosphate (SP) by $17.7 \%$ and $30.0 \%$, respectively. The main effects of $P$ rates were highly significant ( $P \leq 0.01$ ) and affected TC and Car. Application of $P$ in a dose of $35.0 \mathrm{~kg} \mathrm{Pha}^{-1}$ compared to the control significantly increased TC and Car by $18.5 \%$ and $29.2 \%$, respectively. TC increased gradually with increasing P rate and application of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ in SP and UP source caused the highest values by $20.9 \%$ and $16.7 \%$, respectively compared to the control. Also, Car increased progressively with increasing P rate, the application of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ resulted in the greatest values in SP and UP source by $32.4 \%$ and $27.0 \%$, respectively.

## DNA and RNA of common bean

Table 3 shows the interactive effect of phosphorus fertilization source and rate on the nucleic acids (DNA and RNA) of common bean plants grown under salinity stress. Moreover, the significance of the F test of analysis of variance was shown in Table 3. Urea phosphate significantly increased RNA and DNA compared to SP by $9.8 \%$ and $10.8 \%$, respectively. The main effects of $P$ rates were highly significant ( $P \leq 0.01$ ) and affected RNA and DNA. Application of $P$ with $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ compared to control significantly increased RNA and DNA by $40.9 \%$ and $50.1 \%$, respectively. RNA increased gradually with increasing P rate and application of 35.0 kg P ha ${ }^{-1}$ in SP and UP source caused the highest values by $39.8 \%$ and $42.0 \%$, respectively compared to the control. Also, DNA increased gradually with increasing P rate and application of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ resulted in greatest values in SP and UP source by $42.3 \%$ and $57.2 \%$, respectively.

## Ion concentration of common bean

The interactive effect of different sources and rates of phosphorus fertilization on macro-nutrients ( $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}$ ), and $\mathrm{Na}^{+}$of common bean plants grown under salt-affected soil ( $5.21 \mathrm{dS} \mathrm{m}^{-1}$ ) were shown in Table 4. The significance of the $F$ test of analysis of variance was shown also in Table 4. The main effects of $P$ source were
significant $(P \leq 0.05)$ in shoot N , shoot $\mathrm{Ca}^{2+}$, shoot $\mathrm{Mg}^{2+}$ and root N , highly significant $(P \leq 0.01)$ in shoot N , shoot $\mathrm{K}^{+}$, shoot $\mathrm{Na}^{+}$, and root P , while was non-significant in root $\mathrm{K}^{+}$, root $\mathrm{Ca}^{2+}$, root $\mathrm{Mg}^{2+}$, and root $\mathrm{Na}^{+}$. Application of UP increased all macro-nutrients in both shoot and roots, while reduced $\mathrm{Na}^{+}$in shoot and root as well, compared to SP. The main effects of P rates were highly significant $(P \leq 0.01)$ and affected in all aforesaid traits as shown in Table 4. However, P reduced $\mathrm{Na}^{+}$in shoots and roots and this reduction was in parallel with increasing P rate to the dose of $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. Under the interactive effect of P source and P rate, application of P increased $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}$, and $\mathrm{Mg}^{2+}$ of shoots till $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$, whereas shoot $\mathrm{Ca}^{2+}$ increased gradually to the dose of $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. In roots, application of P enhanced $\mathrm{N}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}$ to the dose of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$, while $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$ decreased these nutrients compared to $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. However, the P application increased P and Mg to $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. Application of P boosted P concentration in shoots by $26.3 \%$ and $42.1 \%$ under SP, and UP, respectively when P in a dose of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$ was applied. Moreover, P application resulted in a reduction in shoot $\mathrm{Na}^{+}$ by $27.6 \%$ and $29.3 \%$ in SP, and UP, respectively, while the reduction in roots $\mathrm{Na}^{+}$was by $21.1 \%$ and $22.2 \%$ in SP, and UP, respectively. The response in $\mathrm{Na}^{+}$concentration as P application reduced $\mathrm{Na}^{+}$gradually with increasing P rate regardless of P source. The highest $P$ rate resulted in the lowest $\mathrm{Na}^{+}$concentration either in shoots or roots. The response due to P application may refer to P rate more than P source.

Table 5 shows the interactive effect of different sources and rates of phosphorus fertilization on micro-nutrients $\left(\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Cu}^{2+}\right)$, in shoots and roots of common bean plants grown under salt-affected soil $\left(5.21 \mathrm{dS} \mathrm{m}{ }^{-1}\right)$. The significance of the F test of analysis of variance was shown also in Table 5. The main effects of $P$ source were significant $(P \leq 0.05)$ in shoot $\mathrm{Fe}^{3+}$, shoot $\mathrm{Mn}^{2+}$, root $\mathrm{Zn}^{2+}$, and highly significant $(P \leq$ 0.01 ) in root $\mathrm{Cu}^{2+}$. P application in UP source increased $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ in shoot and $\mathrm{Zn}^{2+}$ in root compared to SP source (Table 5). The main effects of P rates were highly significant $(P \leq 0.01)$ and affected in all micro-nutrients in shoots and roots as shown in Table 5. Application of P increased $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ in shoot till 35.0 $\mathrm{kg} \mathrm{P} \mathrm{ha}{ }^{-1}$, while $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$ decreased these nutrients compared to $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. However, P reduced $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}$, and $\mathrm{Cu}^{2+}$ in roots and this reduction was in parallel with increasing $P$ rate till $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. Under the interactive effect of P source and P rate, $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$, the F test was no significant in both shoots and roots. $\mathrm{Fe}^{3+}$ and $\mathrm{Mn}^{2+}$ in shoots and its increase was gradient with increasing P rate till 52.5 kg P $\mathrm{ha}^{-1}$. However, the application of P in either SP or UP increased $\mathrm{Zn}^{2+}$ and $\mathrm{Cu}^{2+}$ till $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$, while $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ decreased both $\mathrm{Zn}^{2+}$ and $\mathrm{Cu}^{2+}$ compared to $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. Generally, P application increased micro-nutrients in roots of common bean and this reduction was in parallel with increasing P rate.

Interactive effect of different sources and rates of P fertilization on $\mathrm{K}^{+}: \mathrm{Na}^{+}$and $\mathrm{Ca}^{2+}: \mathrm{Na}^{+}$ ratios in shoots and roots of common bean plants grown under salt-affected soil were shown in Table 6. The significance of the $F$ test of analysis of variance was shown in Table 6. The main effects of P source were significant $(P \leq 0.05)$ in $\mathrm{K}^{+}: \mathrm{Na}^{+}$and $\mathrm{Ca}^{2+}: \mathrm{Na}^{+}$ ratios in shoots and UP increased significantly these ratios in both shoots and roots compared to SP. The main effects of P rates were highly significant $(P \leq 0.01)$ and affected
in all aforesaid traits as shown in Table 6. In general, the application of P increased $\mathrm{K}^{+}: \mathrm{Na}^{+}$ and $\mathrm{Ca}^{2+}: \mathrm{Na}^{+}$ratios in both shoots and roots of common bean, and this increase coincided with increasing P rate to $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$. However, $\mathrm{Ca}^{2+}: \mathrm{Na}^{+}$ratios in roots scored the highest value at $35.0 \mathrm{~kg} \mathrm{Pha}^{-1}$. Under the interactive effect of P source and $P$ rate, only $\mathrm{K}^{+}: \mathrm{Na}^{+}$ratio in roots, the F test was highly significant ( $P \leq 0.05$ ). In general, UP was significantly higher or without significant difference with SP in both $\mathrm{K}^{+}: \mathrm{Na}^{+}$and $\mathrm{Ca}^{2+}$ : $\mathrm{Na}^{+}$ratios either in shoots or roots.

## Growth and biomass yield of common bean

The growth parameters which included plant height, leaf area per plant, shoot dry weight $(\mathrm{g})$, root dry weight $(\mathrm{g})$, total dry weight per plant $(\mathrm{g})$ and total dry weight per ha ( t ) were shown in Table 7. In addition, the significance of the F test of analysis of variance was shown in Table 7. The main effects of P source and rate were significant $(P \leq 0.05)$ on all mentioned traits. UP increased all traits compared to $S P$. The main effects of $P$ rates were highly significant ( $P \leq 0.01$ ) and affected all aforesaid traits in Table 7. UP source of $P$ increased total dry weight yield $\left(\mathrm{t} \mathrm{ha}^{-1}\right)$ by $18.7 \%$ compared to SP. Increasing P rates resulted in increasing all mentioned traits gradually to the dose of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$. For example, $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$, increased total dry weight yield $\left(\mathrm{t} \mathrm{ha}{ }^{-1}\right)$ by $93.8 \%$ compared to the control. Also, the interaction effect of P source and P rate was highly significant ( $P \leq 0.05$ ) for all mentioned traits except plant height. The interactive effects increased all growth traits, consequently increased the main target of total dry weight ( $\mathrm{th} \mathrm{h}^{-1}$ ). All traits increased gradually with increasing P rate and application $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ either in SP or UP source increased significantly all traits. Application of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ either in SP or UP increased total dry weight $\left(\mathrm{tha}{ }^{-1}\right)$ by $84.9 \%$ and $101.9 \%$, respectively compared to control plants. We found a significant association between leaf area per plant and total dry weight ( $\mathrm{tha}{ }^{-1}$ ), where the correlation co-efficient was highly significant ( $r=0.994$ ).

## Correlation matrix

Pearson's correlation coefficients (above diagonal) between plant dry weight (shoot dry weight and/or total dry weight per plant) and all nutrients measured in shoots of common bean plants grown with different sources and rates of phosphorus under salt-affected soil were shown in Table 8. There was a positive significant association between shoot dry weight and total dry weight with $r=1(P \leq 0.01)$. There was a positive significant correlation between total dry weight and $\mathrm{N}, \mathrm{P}, \mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$, which were associated with one another. Besides, there was a negative association between either shoot dry weight or total dry weight and $\mathrm{Na}^{+}(P \leq 0.01)$.

Table 9 showed Pearson's correlation coefficients (below diagonal) between plant dry weight (root dry weight and total dry weight) and all nutrients measured in roots of common bean plants fertilized with different sources and rates of phosphorus and grown under salt-affected soil. There was a positive significant association between root dry weight and total dry weight with $r=1(P \leq 0.01)$. There was a positive significant correlation between total dry weight and each of $\mathrm{P}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}$, and $\mathrm{Zn}^{2+}$, which were

Table 8 Pearson's correlation coefficients (above diagonal) among plant dry weight (shoot dry weight and total dry weight per plant) and all measured nutrients in the shoot of common bean plants grown under salinity stress ( $n=8$ ).

## Note:

${ }^{* *}$ and ${ }^{*}$, significant at 0.01 and 0.05 levels respectively; ns, non-significant. N , nitrogen; P, phosphorus; $\mathrm{K}^{+}$, potassium; $\mathrm{Ca}^{2+}$, calcium; $\mathrm{Mg}^{2+}$, magnesium; $\mathrm{Na}^{+}$, sodium; $\mathrm{Fe}^{3}$ ${ }^{+}$, iron; $\mathrm{Mn}^{2+}$, manganese; $\mathrm{Zn}^{2+}$, zinc; $\mathrm{Cu}^{2+}$, copper; RDW, root dry weight; TDW, total dry weight.
associated with one another. Also, there was a negative association between total dry weight and each of $\mathrm{N}, \mathrm{Na}^{+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}$, and $\mathrm{Cu}^{2+}(P \leq 0.01)$.

## Response curve of biomass yield to phosphorus fertilizer rate

Linear and quadratic responses of common bean plants total dry weight ( $\mathrm{tha}{ }^{-1}$ ) grown under salinity stress to different rates of phosphorus $\left(\mathrm{kg} \mathrm{ha}^{-1}\right)$ using different forms of phosphorus, i.e., superphosphate (A), urea phosphate (B), and at an average combined of superphosphate and urea phosphate (C) are shown in Fig. 1. Under superphosphate (A),

Figure 1 Response curve of total dry weight ( $\mathbf{t ~ h a}{ }^{-1}$ ) to different rates of phosphorus ( $\mathbf{k g ~ h a}^{-\mathbf{1}}$ ) using different forms of phosphorus i.e. super superphosphate (A), urea phosphate (B), and at an average combined of superphosphate and urea phospha (C) in common bean plants grown under salinity stress. Full-size DOI: 10.7717/peerj.11463/fig-1
with a P level increased of $1.0 \mathrm{~kg} \mathrm{ha}^{-1}$, the total dry weight was expected to increase by $14 \mathrm{~kg} \mathrm{ha}^{-1}$. The $\mathrm{R}^{2}$ value, defined as the regression sum of squares divided by the total sum of squares, increased from $74.8 \%$ (linear) to $84.8 \%$ (quadratic), so $84.8 \%$ of the variation in total dry weight yields was explained by quadratic regression model. In the quadratic curve, total dry weight, equal $1.675 \mathrm{tha}^{-1}$, was the maximum if P was applied at a level of $51.5 \mathrm{~kg} \mathrm{ha}^{-1}$, and the expected TDW should be $1.675 \mathrm{tha}^{-1}$. Under urea phosphate (B), with a $P$ level increase of $1.0 \mathrm{~kg} \mathrm{ha}^{-1}$, the total dry weight was expected to increase by $18 \mathrm{~kg} \mathrm{ha}^{-1}$. The mentioned value increased from $74.6 \%$ (linear) to $86.1 \%$ (quadratic). Thus, if P was applied at a level of $42.5 \mathrm{~kg} \mathrm{ha}^{-1}$, the maximum expected total dry weight would be
$1.875 \mathrm{tha}^{-1}$. Under average combined of superphosphate and urea phosphate (C), with a P level increased of $1.0 \mathrm{~kg} \mathrm{ha}^{-1}$, the total dry weight was expected to increase by $16 \mathrm{~kg} \mathrm{ha}^{-1}$. This has increased from $74.7 \%$ (linear) to $85.6 \%$ (quadratic). Hence, if P was applied at a level of $45.9 \mathrm{~kg} \mathrm{ha}^{-1}$, the maximum expected total dry weight would be $1.768 \mathrm{tha}{ }^{-1}$.

## DISCUSSION

Leaf chlorophyll is one of the most important physiological measures of biochemical characteristics, indicating the stress of the plant, partly because of its dependence on water and nutritious accessibility (Bargaz et al., 2016; El-Lethy, Abdelhamid \& Reda, 2013). The photosynthetic pigments content decrease in conditions of salinity stress (Bargaz et al., 2016). In the present study, the reduced total chlorophyll (TC) content was confirmed as a result of salinity stress affecting common bean plants metabolism. Likewise, the carotenoids (Car) concentration was reduced in parallel (Table 2). Additionally, there was a significant linear correlation between the total chlorophyll content in the leaves and total dry weight yield per hectare ( $r=0.777, P \leq 0.01$ ), as well as between total carotenoid and total dry weight yield per hectare ( $r=0.778, P \leq 0.01$ ). The decrease in chlorophylls' content in plants grown in stress conditions could be attributable to thylakoid membrane disorganization, and to degradation of chlorophyll caused by proteolytic enzymes such as chlorophyllase (Rong-Hua et al., 2006). Mentioned processes could lead to a decrease of the net assimilation rate and-in consequence relative growth rate of plants (Rady et al., 2015). The inhibitory effect of accumulated $\mathrm{Na}^{+}$ions could also participate in described phenomenon (Abdelhamid, Shokr \& Bekheta, 2010; Dawood, Abdelhamid \& Schmidhalter, 2014). The improvement in the content of chlorophyll and carotenoids due to P application may be due to more effective absorption of elements from soil, particularly Mg , a key component of the chlorophyll molecule (Sheng et al., 2008). In short, a higher content of chlorophyll in plants contributes to accelerated photosynthetic activity and more intensive growth and higher dry weight yield.

In stressed plants, the reduction in nucleic acids (DNA and RNA) can be attributed to the reactive oxygen species (ROS) released to cell components in salt stress conditions. ROS induce DNAase activity, accelerating DNA fragmentation (Sadak, Abdelhamid \& Schmidhalter, 2015; Tsenov, Strogonov \& Kabanov, 1973). The content of DNA and RNA in maize seedlings has been postulated to be decreased under salt stress due to inhibition of nucleic acids synthesis and intensification of their breakdown (Zeid, 2009b). Plant growth, directly associated with cell division, diversification, and elongation were negatively affected by salinity through reduction of the cellular water content and decreasing of nucleic acids, which are crucial for all anabolic processes. In bean, Zeid (2009a) determined that the decrease in nucleic acids content was linked to accelerated RNase activity causing their degradation. Kabanov \& Aziyashvili (1976) associated the depression of DNA and RNA metabolism to the abundance of $\mathrm{Na}^{+}$cations in cells, reduction of phosphorus incorporation into nucleic acids and also to intensified RNase activity in cytoplasm. In the present study, a significant linear correlation was determined between the RNA in the leaves of common bean and total dry weight yield per hectare ( $r=0.985, P \leq 0.01$ ), and between DNA and total dry weight yield per hectare ( $r=0.954$;
$P \leq 0.01$ ). Moreover, the application of P using both P sources promoted the synthesis of nucleic acids and could prevent their degradation by nuclease enzymes (Table 3).

Plant growth is based on a sufficient supply of N transformed to form amino acids, proteins, nucleic acids, and other cellular components for various parts of the plant and translocated into the plant kernels that develop intensively. P and $\mathrm{K}^{+}$are involved in mitigating the salinity stress in most of plant crops (El-Lethy, Abdelhamid \& Reda, 2013; Bargaz et al., 2016; Chakraborty et al., 2016). For example, $\mathrm{P}, \mathrm{K}^{+}$, and indole-3-acetic acid (IAA) were effective in improving the maize plants fitness while exposed to the salinity stress (Kaya et al., 2013). Besides, it was reported that P application at a doses of 50, 100, and $150 \mathrm{mg} \mathrm{g}^{-1}$ increased root length, cotyledon length and width, and hypocotyls length, contents of $\mathrm{N}, \mathrm{P}, \mathrm{Mn}^{2+}$, and $\mathrm{Cu}^{2+}$ in shoot and $\mathrm{P}, \mathrm{Ca}^{2+}$ in the root, and decreased $\mathrm{Fe}^{3+}$ and $\mathrm{Zn}^{2+}$ in the shoot, $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ in the root of pepper plants (Çimrin et al., 2010). Also, a significant reduction in $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}$, and $\mathrm{Mg}^{2+}$, while $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$increased were found in salinity stress conditions in faba bean plants (Abdelhamid, Shokr \& Bekheta, 2010; Rady et al., 2015). The decrease of N, P, and K ${ }^{+}$was observed in common bean plants irrigated with different concentrations of NaCl , while $\mathrm{Na}^{+}$increased in tissues (Dawood, Abdelhamid \& Schmidhalter, 2014; Sofy et al., 2020b). In the present study, the highest rate of $\mathrm{P}\left(52.5 \mathrm{~kg} \mathrm{ha}^{-1}\right)$ resulted in a significant reduction of $\mathrm{Na}^{+}$ content in the shoot and root of common bean. These findings are similar to those reporting that various levels of P applied as a foliar spray caused a reduction in the content of $\mathrm{Na}^{+}$in the shoot of wheat plants (Ghonaim, Mohamed \& Omran, 2021). In sandy and calcareous soils, application of P alleviated the stressful effect of moderate and high salinity in wheat plants, while $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}$, and $\mathrm{Zn}^{2+}$ absorption increased (Wagdi et al., 2013).

High cellular $\mathrm{K}^{+}: \mathrm{Na}^{+}$ratio, crucial for balanced cell processes, can be maintained in salinity stress conditions also through enhanced uptake of $\mathrm{K}^{+}$and/or $\mathrm{Ca}^{2+}$ causing reduced uptake of $\mathrm{Na}^{+}$(Ghonaim, Mohamed \& Omran, 2021; Kavitha et al., 2012).

The present study revealed that in the shoot of common bean, the highest value in $\mathrm{N}, \mathrm{P}$, $\mathrm{K}^{+}, \mathrm{Mg}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Cu}^{2+}$ were obtained using $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ compared to the other rates of P fertilizer. Also, the $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}{ }^{-1}$ gave the highest value on $\mathrm{N}, \mathrm{K}^{+}$, and $\mathrm{Ca}^{2+}$ in the root of the common bean. The highest $P$ application rate of $52.5 \mathrm{~kg} \mathrm{ha}^{-1}$ resulted in a significant reduction in $\mathrm{Na}^{+}$in shoot and root. These findings are similar to the report that $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Zn}^{2+}, \mathrm{Fe}^{3+}$, and $\mathrm{Mn}^{2+}$ increased in two common bean recombinant inbred lines (RILs) 115 (P-deficiency tolerant) and 147 (P-deficiency susceptible) with higher P concentrations (Kandil, Gad \& Abdelhamid, 2013). Also, the application of P caused higher N absorption and accumulation in chickpea plants (Shukla, Singh \& Deshbhratar, 2010).

The dose and salt dependent P action as plant stress-defender was confirmed in some research. P fertilizer at a dose of $40 \mathrm{~kg} \mathrm{ha}^{-1}$ increased $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}$, and $\mathrm{Ca}^{2+}$ content in maize (Hussaini et al., 2008). P at a rate of $60 \mathrm{~kg} \mathrm{ha}^{-1}$ of triple superphosphate enhanced N , $\mathrm{P}, \mathrm{Ca}^{2+}$, and $\mathrm{K}^{+}$accumulation in lentil (Al-Darkazli, Al-Saedy \& Al-Saadi, 2011). Similar results were reported by researchers for many crops, like barley (Mehrvarz \& Chaichi, 2008) and faba bean (El-Gizawy \& Mehasen, 2009). Moreover, P supported the development of a strong root system of lentil plants causing better capacity to absorb $\mathrm{N}, \mathrm{P}$,
$\mathrm{K}^{+}$, and $\mathrm{Ca}^{2+}$ from the soil, and, consequently contents of mentioned minerals increased after the phosphorus application (Singh \& Singh, 2016). High P fertilization promoted vegetative growth and the formation of well-developed root systems that efficiently absorb maximum soil nutrients (Sharma \& Gupta, 2002).

Çimrin et al. (2010) pointed out that humic acid and P application positively affected the growth of pepper seedlings. Moreover, humic acid and $P$ interacted in increasing $N, P, K^{+}$, $\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}, \mathrm{S}, \mathrm{Mn}^{2+}$, and $\mathrm{Cu}^{2+}$ contents of pepper seedlings' shoot. The application of chemical P enhanced plant growth parameters and raised $\mathrm{N}, \mathrm{P}$, and $\mathrm{K}^{+}$content in eggplant compared to the organic P fertilizer (Lima et al., 2014). Besides, P in any form increased the nutritional values of common bean, i.e., protein, $\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}, \mathrm{Mn}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Cu}^{2+}$, and $\mathrm{Fe}^{3+}$ contents (Bargaz et al., 2016).

Phosphorus is crucial for cell division, resulting in an increased growth, number of side branches, and in consequence, the dry weight of the plant (Tesfaye et al., 2007). Hasan et al. (2013) noted that the maximum growth parameters of brinjal were at 60 kg P ha . Whilst, Attar et al. (2012) found that $90 \mathrm{~kg} \mathrm{ha}^{-1}$ phosphorus pentoxide applied to the sandy soils, resulted in optimum growth parameters of the common bean, while control plants showed the lowest growth values. Also, it was reported that the application of P improved both, growth parameters and yield, of mung bean (Abdalsalam \& Al-Shebani, 2010). The plant height and dry weights of shoot and roots decreased in plants grown in high salinity conditions which is in line with previous reports (Awad et al., 2012; El-Beltagi et al., 2013; El-Lethy, Abdelhamid \& Reda, 2013; Naeem et al., 2020). Our findings are also in agreement with those of Khan et al. (2013). The highest value of shoot dry weight of plants treated with $P$ was possibly due to the significant increased the area of the leaf per plant, which increased the area available for photosynthesis and biomass production.

In this study, the decline in total dry weight yield can be due to decreased photosynthetic pigments and nucleic acids content (Tables 2 and 3), disruption in nutrient balance (Tables 4 and 5) and reduced plant growth (Table 7). In this research, in a linear way, LA and total dry weight yield per ha were correlated with each other. P application at $35.0 \mathrm{~kg} \mathrm{ha}^{-1}$ rate caused significant increases in total dry weight yield compared to the corresponding control. Our finding confirmed that high rate of $P$ ( $52.5 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ ) had harmful effects on common bean plants. In this regard, a detrimental reverse effect of high P rate was recorded in common bean (Bargaz et al., 2016) and other crops such as Oryza sativa (Aslam et al., 1996), which does not make the available salinity and $P$ interactive effect data adequately consistent and a large number of grain and forage legumes need to be considered at large $P$ levels.

## CONCLUSIONS

In conclusion, the results obtained from this study have demonstrated that phosphorus fertilization significantly increased all growth parameters, chlorophyll content, nucleic acid content and minerals content of the common bean plants. Moreover, phosphorus applied at a dose of $35.0 \mathrm{~kg} \mathrm{P} \mathrm{ha}^{-1}$ was more efficient compared to other treatments. Mentioned $P$ dose resulted in the highest values of investigated parameters crucial for common bean growth and productivity, including chlorophylls, carotenoids, DNA, RNA,
$\mathrm{N}, \mathrm{P}, \mathrm{K}^{+}$, and $\mathrm{Mg}^{2+}, \mathrm{Zn}, \mathrm{Cu}$, and $\mathrm{K}^{+}: \mathrm{Na}^{+}$of shoot, $\mathrm{N}, \mathrm{K}, \mathrm{Ca}^{2+}, \mathrm{K}^{+}: \mathrm{Na}^{+}$, and $\mathrm{Ca}^{2+}: \mathrm{Na}^{+}$of root, leaf area, shoot dry weight, root dry weight, total dry weight per plant, and total dry weight per hectare. The application of phosphorus as urea phosphate was more effective than single superphosphate in alleviating salinity stress.

## ACKNOWLEDGEMENTS

The authors are grateful to the anonymous reviewers for their valuable comments and Suggestions.

## ADDITIONAL INFORMATION AND DECLARATIONS

## Funding

This research was funded by the National Research Centre, Cairo, Egypt, and the University of Agriculture in Krakow, Poland. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

## Grant Disclosures

The following grant information was disclosed by the authors:
National Research Centre, Cairo, Egypt.
University of Agriculture in Krakow, Poland.

## Competing Interests

The authors declare that they have no competing interests.

## Author Contributions

- Heba I. Mohamed performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Adel A. El-Sayed conceived and designed the experiments, performed the experiments, authored or reviewed drafts of the paper, and approved the final draft.
- Mostafa M. Rady analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Gianluca Caruso analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Agnieszka Sekara analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Magdi T. Abdelhamid conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.

## Data Availability

The following information was supplied regarding data availability:
The raw measurements are available in the Supplemental File.

## Supplemental Information

Supplemental information for this article can be found online at http://dx.doi.org/10.7717/ peerj.11463\#supplemental-information.
