Background: *Stephadiscus lyratus* (Couthouy in Gould, 1846), an endemic Charopidae from southern South America, was described from few dry shells. In the same way, species distribution is known on scatter occurrences, mainly from material deposited in Museum collections. We provide here new information on anatomy, habitat and microhabitat preferences and estimate the potential geographic distribution of the species to test if it is exclusively endemic to the Subpolar Magellanic Forest. **Methods:** Fieldwork was carried out in National Parks of the Patagonian Forests. Snails were photographed, measured and dissected for anatomical studies; shells studied with scanning electron microscopy. Estimation of the species geographical distribution (EGD) was obtained through correlative ecological niche modeling (ENM). We designed a calibration area a priori with known species points of occurrence in the Magellanic Subpolar Forests and borders of Patagonian steppe. Seven bioclimatic variables of WorldClim database were used. The best ENMs were calibrated and selected using a maximum entropy method with Maxent v3.3.3K through the R package "kuenm". Candidate models were created by combining 4 values of regularization multiplier and all possible combinations of 3 feature classes. We evaluated candidate model performance based on significance (partial ROC), omission rates ($E = 5\%$), and model complexity (AICc). From the best models obtained, a final model was transferred to a region "G" consisting of the calibration area plus the Valdivian Temperate Forests and whole Patagonian steppe, where we hypothesize that the species could be present. Finally, we obtained binary presence-absence maps. We quantified the proportion of the occurrence points and distribution range of *S. lyratus* in different land cover categories. To explore the degree of protection of *S. lyratus*' EGD, we quantified the proportion of its distributional range within protected areas. **Results:** A be-lobed kidney, a close secondary ureter, the terminal portion of the uterus forming a compact glandular

mass and the vas deferens with a dilatation are new anatomical information provided. *Stephadiscus lyratus* inhabit cold native forest areas, mainly living on or under humid logs in contact with the ground. Main constraining variables to explain *S. lyratus* distribution in the EGD were BIO3, BIO12, BIO6 and BIO4. The potential area of distribution obtained almost duplicates their original range (140,454 Km²) extending to the Valdivian Temperate forests mainly in Chile. Natural and semi-natural terrestrial vegetation was predominant in the potential area of distribution of *S. lyratus*. However, only 14.7% of this area occurs within current protected areas from Argentina and Chile. The ectothermic physiological traits of this species, low dispersal capacity, and its narrow habitat requirements turns *S. lyratus* into a vulnerable species.

17 **Abstract**

18 **Background:** *Stephadiscus lyratus* (Couthouy in Gould, 1846), an endemic Charopidae from
19 southern South America, was described from few dry shells. In the same way, species
20 distribution is known on scatter occurrences, mainly from material deposited in Museum
21 collections. We provide here new information on anatomy, habitat and microhabitat preferences
22 and estimate the potential geographic distribution of the species to test if it is exclusively
23 endemic to the Subpolar Magellanic Forest. **Methods:** Fieldwork was carried out in National
24 Parks of the Patagonian Forests. Snails were photographed, measured and dissected for
25 anatomical studies; shells studied with scanning electron microscopy. Estimation of the species
26 geographical distribution (EGD) was obtained through correlative ecological niche modeling
27 (ENM). We designed a calibration area a priori with known species points of occurrence in the
28 Magellanic Subpolar Forests and borders of Patagonian steppe. Seven bioclimatic variables of
29 WorldClim database were used. The best ENMs were calibrated and selected using a maximum
30 entropy method with Maxent v3.3.3K through the R package "kuenm". Candidate models were
31 created by combining 4 values of regularization multiplier and all possible combinations of 3
32 feature classes. We evaluated candidate model performance based on significance (partial ROC),
33 omission rates ($E = 5\%$), and model complexity (AICc). From the best models obtained, a final
34 model was transferred to a region "G" consisting of the calibration area plus the Valdivian
35 Temperate Forests and whole Patagonian steppe, where we hypothesize that the species could be
36 present. Finally, we obtained binary presence-absence maps. We quantified the proportion of the
37 occurrence points and distribution range of *S. lyratus* in different land cover categories. To
38 explore the degree of protection of *S. lyratus*' EGD, we quantified the proportion of its
39 distributional range within protected areas. **Results:** A be-lobed kidney, a close secondary ureter,
40 the terminal portion of the uterus forming a compact glandular mass and the vas deferens with a
41 dilatation are new anatomical information provided. *Stephadiscus lyratus* inhabit cold native
42 forest areas, mainly living on or under humid logs in contact with the ground. Main constraining
43 variables to explain *S. lyratus* distribution in the EGD were BIO3, BIO12, BIO6 and BIO4. The
44 potential area of distribution obtained almost duplicates their original range (140,454 Km²)
45 extending to the Valdivian Temperate forests mainly in Chile. Natural and semi-natural
46 terrestrial vegetation was predominant in the potential area of distribution of *S. lyratus*. However,
47 only 14.7% of this area occurs within current protected areas from Argentina and Chile. The

48 ectothermic physiological traits of this species, low dispersal capacity, and its narrow habitat
49 requirements turns *S. lyratus* into a vulnerable species.

50

51 **Introduction**

52 Charopidae is a family of Punctoidea land gastropods with an extensive distribution that includes
53 South America, South Africa, Australia, New Zealand, and Oceania (Salvador et al., 2020).

54 Southern Argentina and Chile are particularly rich in endemic species of Charopidae (Miquel &

55 Cádiz Lorca, 2008). Hylton Scott (1964, 1968, 1970, 1973, 1981) was the researcher that most

56 studied and described Charopidae species in South America. Unfortunately, most of her

57 descriptions were based on a single or few dry shells, which resulted in the absence of

58 intraspecific shell variability studies. The lack of species anatomical data constitutes a barrier for

59 intra family taxonomy. Also, adequate fieldwork to estimate the current distributional range of

60 Charopidae genera and species in South America has not been done.

61 *Stephadiscus* Hylton Scott, 1981 originally included some species that are currently classified in

62 *Stephanoda* Albers, 1860, and *Stephacharopa* Miquel & Araya, 2013 (Miquel & Barker, 2009;

63 Miquel & Araya, 2013). At present, the genus is formed by six species, *Stephadiscus lyratus*

64 [designated as the genus type species], *S. celinae* (Hylton Scott, 1969), *S. mirabilis* (Hylton

65 Scott, 1968), *S. perversus* (Hylton Scott, 1969), *S. rumbolli* (Hylton Scott, 1973), and *S. stuardoi*

66 Miquel & Barker, 2009. The taxonomic position of *Stephadiscus striatus* Hylton Scott, 1981

67 from northeastern Argentina and Venezuela, should have to be reconsidered, as it appears to

68 belong to Punctidae (Miquel & Barker, 2009). Known *Stephadiscus* distribution is restricted to

69 Patagonia at both sides of the Andes from S 36° towards the southernmost portion of the

70 continent, including Malvinas islands (=Falklands) and southern archipelagos (Miquel & Barker,

71 2009; Miquel & Araya, 2013) and belong to the Andean region (Morrone, 2018). This

72 biogeographic area has a closer relationship to the Austral region in the Austral kingdom

73 (Morrone, 2015, 2018). Current distributional range of *Stephadiscus lyratus* (Couthouy in Gould,

74 1846) had been established on scattering points of occurrences taken from its original

75 description, and subsequent species mentions (Gould, 1845-1848; Hylton Scott, 1972, 1981;

76 Miquel & Araya, 2013, see "Species remarks" section). Erroneous taxonomic identified material

77 from Museum Collections suggested the presence of this species in the forests of northern

78 Patagonia, even though Hylton Scott (1981) stated that *S. lyratus* could be a strictly Magellanic

79 species. While *Stephadiscus celinae*, *S. perversus*, and *S. mirabilis* also occur in the Valdivian
80 rainforest sub-ecoregion of northern Patagonia, *S. rumbolli* is exclusively from the southern sub-
81 ecoregions. For this reason, there are doubts as to whether the distribution of *S. lyratus* extends
82 naturally to the Valdivian rainforest or it is restricted to southern areas.

83 Modern methodologies to estimate a species distributional area involves the ecological niche
84 models (ENMs) that relate the species distribution data (species occurrence at known locations)
85 with information about the environment (abiotic factors) (Beltramino et al., 2015; Medina,
86 Ponsa & Aráoz, 2016). The environmental variables of the localities of occurrence are also
87 informative about the species' potential distribution. Estimates of geographic range obtained by
88 ENM techniques when data are scarce, or when species are rare, have proven to be more
89 successful than those obtained by traditional methods
90 (e.g., minimum convex polygon) (Marcer et al., 2013; Syfert et al., 2014; Pena et al., 2014).
91 These also allow avoiding the potential subjective bias of experts (Fourcade et al., 2014).
92 Furthermore, identifying the combination of environmental condition in the relevant scenopoetic
93 variables offers the opportunity to discover populations isolated (Wiens & Graham, 2005). On
94 the other hand, modeling species potential areas of distribution may also provide information on
95 the geographic distribution of unknown sister species (Peterson et al., 2011).

96 Invertebrates are recognized as indicators of human disturbance, due to their low dispersal
97 capacity and their dependence on microhabitats for survival and mating. Particularly, most snails
98 that are not arboreal are dependent on litter from deciduous trees and have higher abundances in
99 multispecies forests with strong broadleaf components (Addison & Barber, 1997; Niemelä,
100 1997). Taking into account that many natural areas to date are severely fragmented or threatened
101 by human activities, obtaining information on the ecological aspects of these species is very
102 useful for future biological conservation work (Barahona-Segovia et al., 2019). Previous studies
103 in *Stephadiscus lyratus* provided few data on habitat or microhabitat preferences and therefore
104 future evaluation on its risk of extinction will need ecological information on this species. The
105 objective of this research is to provide new information on the anatomy and ultrastructure of the
106 *Stephadiscus lyratus* shell, using recently collected material, identifying and describing the
107 microhabitat where it is found, and analyzing the environmental variables that are limiting its
108 distribution with ENMs techniques.

109 Finally, we estimate its potential geographic distribution to hypothesize if *S. lyratus* can also be
110 distributed in the Valdivian Temperate Forest or if this species is endemic exclusively to the
111 Magellanic Subpolar Forest.

112

113 **Material and Methods**

114 **Study area** (Fig. 1A, B)

115 Fieldwork was carried out in the Patagonian Forests, also known as the temperate forest of
116 southern South America that extends in a narrow strip of land over the Andes Mountain between
117 35° and 55° south latitude (Armesto et al., 2001). In Argentina, this region occupies the western
118 zone from the provinces of Neuquén to Tierra del Fuego and islands of the southern Atlantic.
119 The Patagonian Forests are divided into two different areas, the northern Valdivian Temperate
120 and the southern Magellanic Subpolar Forest ecoregions *sensu* Olson & Dinnerstein (1998),
121 Olson et al. (2001) and Morello et al. (2012) or sub-ecoregions *sensu* Dos Santos et al. (2020).
122 We followed here this last mentioned classification.

123 The Valdivian Temperate Forest (Fig. 1A) covers a narrow area running from 35° to 48° south
124 latitude between Chile and Argentina. Annual precipitation varies between 1,000 mm in the
125 north and more than 6,000 mm per year in the southern part of the sub-ecoregion. This seasonal
126 precipitation decreases significantly on the eastern slope of the Andes in Argentina, where
127 rainfall of less than 200 mm is recorded only 100 km east of the Andean peaks. Maximum
128 annual average temperatures vary between 21 °C and 13 °C in the northern and southern ends of
129 the sub-ecoregion. Minimum annual average temperatures range from 7 °C to 4 °C
130 (<https://www.worldwildlife.org/ecoregions/nt0404>). Biogeographically, these forests share
131 floristic similarities with other temperate forests in the southern hemisphere located in Australia
132 and New Zealand (McGlone et al., 2016). However, there is a high degree of endemism not only
133 in the flora but also in the fauna at species level.

134 The southern areas of the Magellanic Subpolar Forests are well represented in Tierra del Fuego,
135 where they occupy the entire south of the province (Fig. 1A, B). However, dominant vegetation
136 is a forest of less species diversity in comparison to the Valdivian rainforest due to the low
137 temperatures and rainfall.

138 Tierra del Fuego or Fueguia is the archipelago located south of the Strait of Magallanes between
139 52° 28'S and 55° 03'S; it occupies about 66,000 km² (Fig. 1A). The main island is Isla Grande,

140 with 48,000 km² representing 70% of the surface of the archipelago, from which 21,263 km²
141 belongs to Argentina (Frangi et al., 2004). The vegetation of the island is mainly formed by a
142 Patagonian steppe of grasslands and shrubs located at the northern part, and humid deciduous
143 and evergreen forests plus peat bogs located in the center and southern portion. The trees of the
144 genus *Nothofagus* dominate the forest composition in Tierra del Fuego and constitute the most
145 austral forest in the world as part of the Magellanic Subpolar forest sub-ecoregion. The highest
146 rainfall is recorded in the south of the island, decreasing to the east and center of it. In the south
147 and west of the island it is very windy, foggy and humid most of the year with few days without
148 rain, sleet, hail or snow. The average annual temperature on the island is 5.5 °C to the north and
149 5.9 °C to the south. Above the mountains, the temperature decreases with elevation, these
150 gradients determine temperatures below zero in the winter months (Frangi et al., 2004). The Big
151 Island of Tierra del Fuego and the Islas de Los Estados were modeled by the erosive action of
152 glaciers that covered large portions of land on several occasions. The glacial topography and the
153 temperate-cold and humid climate that prevail throughout the year, favored the formation of the
154 peat bogs that are now part of the Fuegian landscape.

155

156 **Fieldwork and specimen collections**

157 Fieldwork was carried out in the Magellanic Subpolar Forests of Tierra del Fuego National Park
158 (DRPA 146/2019) and other non-preserved areas in Isla Grande of Tierra del Fuego, Argentina,
159 during December 2018 - January 2019 (Figs. 1C, D). In the Valdivian Temperate Forests,
160 fieldwork was done within Los Alerces National Park and Puerto Blest in Nahuel Huapi National
161 Park (DRPA 1674, DFyFS1/19) during January 2020. We qualitatively searched for land snails
162 along transects for half an hour in each collecting site. Searching was mainly focused on
163 microhabitats that seem to be most favorable for snails, such as between exposed roots of trees,
164 under the bark of trees, under rocks, or under tree trunks lying on the forest floor in contact with
165 soil. In each collecting site, we recorded altitude and geographic coordinates. We also took
166 samples of 50x50 cm quadrats of leaf litter plus 2 cm of topsoil from moist microhabitats.
167 Samples were placed in plastic bags and posteriorly sieved through three decreasing mesh widths
168 (3, 1.5, and 0.5 mm) in the laboratory of the Centro Austral de Investigaciones Cientificas
169 (CADIC-CONICET, Tierra del Fuego) under a stereoscopic microscope. All snails collected
170 were photographed alive before relaxing them in water for 24 hours, posteriorly fixed in ethanol

171 96%, and preserved in ethanol 70% for anatomical studies. Several specimens were also fixed
172 directly in ethanol 96%, without relaxation in water, for future molecular studies. All the
173 material collected was deposited in the Malacological Collection of the Instituto de
174 Biodiversidad Neotropical (IBN, CONICET-UNT, Tucumán, Argentina).

175 **Morphology**

176 Ten adult shells were photographed using a Zeiss Stemi 508 with ActionCam and measured
177 using the software ImageJ 1.49 (Schneider, Rasband & Eliceiri, 2012). Shell measurements
178 selected, on dorsal and lateral views, are: major shell diameter (DM), shell minor diameter (Dm),
179 shell height (H), apertural height (Hap), and apertural diameter (Dap). The number of shell
180 whorls was calculated following the Kerney & Cameron (1979) methodology. Photographs and
181 shell measurements were carried out at the CADIC in Tierra del Fuego. For anatomical
182 information, dissections of 7 adult specimens were studied under a Leica MZ6 stereoscope.
183 Illustrations of the dissected organs/systems were carried out with the aid of a camera lucida. The
184 terms proximal and distal refer to the position of an organ or part of an organ in relation to the
185 gamete flow from ovotestis (proximal) to genital pore (distal) as in previous works (Cuezzo,
186 2006; Cuezzo et al., 2018). The distinction of the limits between the epiphallus and penis is
187 based on the internal sculpture of their inner wall. Shell ultrastructure was studied and described
188 using a SEM Zeiss Supra 55VP at the Integral Center of Electron Microscopy (CIME) of the
189 National University of Tucumán, Argentina (UNT).

190

191 **Occurrence records**

192 We compiled a total of 60 geographic records of *Stephadiscus lyratus* from field surveys,
193 museum collections, and scientific articles (Fig. 1, Table S1). Twenty new reliable records were
194 obtained through fieldwork in Tierra del Fuego. To avoid primary taxonomic sources of error
195 from specimens deposited at different Museums, we corroborated the taxonomic identification of
196 specimens according to their shell morphology. The malacological collections of IBN (Instituto
197 de Biodiversidad Neotropical, Tucumán, Argentina), MACN-In (Museo Argentino de Ciencias
198 Naturales Bernardino Rivadavia, Buenos Aires, Argentina), and MLP (Museo de La Plata,
199 Buenos Aires, Argentina) were revised accordingly. Other sources of information were
200 electronic databases from the Smithsonian National Museum of Natural History (NMNH),
201 Museum of Comparative Zoology (MCZ), and Academy of Natural Sciences in Philadelphia

202 (ANSP). We used Google Earth to georeferenced localities of occurrences that lacked
203 geographic coordinates. From the total number of records, we removed duplicate records, which
204 left 37 unique sites with trustable geographic information. To avoid over-representation of
205 certain environmental combinations, we spatially filtered records based on a 5 km radius, which
206 left 24 localities, then we split them in 30% for test and 70% for train the ecological niche model,
207 both functions implemented in R-package “ellipsenm” (Cobos et al., 2020).

208

209 **Estimations of potential geographic distributions (EGDs)**

210 Estimates of the geographical distribution (EGD) of *S. lyratus* were obtained through correlative
211 ecological niche modeling (ENM). To adequately model the species niche, we used the
212 theoretical Biotic-Abiotic-Mobility framework (Soberón & Peterson, 2005). Only abiotic and
213 mobility factors were taken into account because the biotic components (i.e., biotic interactions)
214 are virtually impossible to spatially quantify thoroughly at regional scales (Peterson et al., 2011).
215 As for the mobility component, we designed a calibration area a priori “M” (Barve et al., 2011)
216 considering sub-ecoregions with known species points of occurrence, i.e., in the Magellanic
217 Subpolar Forest and the southern portion of Patagonian steppe. To delineate abiotic components,
218 we used 15 bioclimatic variables of the WorldClim database (Hijmans et al., 2005) at a spatial
219 resolution of 30 arc seconds (~1 km²), excluding the four variables that combine temperature and
220 precipitation owing to be known artifacts (Escobar et al., 2014). We clipped the environmental
221 data layers to the calibration area defined. To eliminate one variable per pair of highly correlated
222 variables ($r \geq 0.85$), we performed a correlation analysis through the "ntbox" package (Osorio-
223 Olvera et al., 2020). Thus, seven bioclimatic variables were selected for the analyses: BIO1 =
224 Annual Mean Temperature, BIO2 = Mean Diurnal Range (Mean of monthly (max temp - min
225 temp)), BIO3 = Isothermality (BIO2/BIO7) (* 100), BIO4 = Temperature Seasonality (standard
226 deviation *100), BIO6 = Min Temperature of Coldest Month, BIO12 = Annual Precipitation, and
227 BIO15 = Precipitation Seasonality (Coefficient of Variation).

228 The best ENMs were calibrated and selected using a maximum entropy method with Maxent
229 v3.3.3K (Phillips, Anderson & Schapire, 2006) through the R package "kuenm" (Cobos et al.,
230 2019). Then, candidate models were created by combining four values of regularization
231 multiplier (0.1, 0.5, 1, 2), and all possible combinations of three feature classes (linear = 1,
232 quadratic = q, product = p). We evaluated candidate model performance based on significance

233 (partial ROC, with 100 iterations and 50 percent of data for bootstrapping), omission rates ($E =$
234 5%), and model complexity (AICc). Best models were selected according to the following
235 criteria: (1) significant models with (2) omission rates $\leq 5\%$. From among this set, models with
236 delta AICc values of ≤ 2 were chosen as final models. The final model was created using the
237 spatially filtered records (24 occurrences) and the selected parameterizations. We produced 100
238 iterations with five replicates by bootstrap, with logistic outputs. We ran the models with no
239 extrapolation or clamping to avoid artificial projections based on extreme values of the
240 bioclimatic variables (Elith et al., 2011; Owens et al., 2013; Merow et al., 2014; Guevara et al.,
241 2018). Then, the final model was transferred to a region "G" consisting of the calibration area
242 plus the Valdivian Temperate Forest and Patagonian steppe regions, where the species could be
243 also present as its congeners. To identify extrapolation risk areas in model transfers, we
244 performed MOP analyses (Owens et al., 2013). This function calculates multivariate
245 environmental distances between sites across the transfer region (G) and the nearest portion of
246 the calibration region to identify areas that have a condition of strict or combinational
247 extrapolation.

248 Finally, to obtain binary presence-absence maps, we used a minimum presence threshold,
249 modified to consider presence data errors (Peterson, Papeş & Eaton, 2007) implemented in R-
250 package "ENMGadgets" (Barve & Barve, 2019). This modified threshold included 100% of the
251 presence points minus the dataset error (E) (Phillips & Dudík, 2008); we assumed $E = 5\%$ based
252 on our experience of obtaining the presence data. This conservative method minimizes the
253 commission error rate.

254

255 **Spatial analysis**

256 To spatially characterize the distribution of *Stephadiscus lyratus* we quantified the proportion of
257 occurrences points and of their potential distribution in different categories of the land cover of
258 the Globcover 2009 dataset (Arino et al., 2012). The 22 land cover categories (e.g., Closed to
259 open (>15%) broadleaved evergreen or semi-deciduous forest (> 5m), Mosaic forest or shrubland
260 (50-70%) / grassland (20-50%)) are according to the UN Land Cover Classification System
261 (LCCS) (Di Gregorio, 2005).

262 To explore the degree of protection of *S. lyratus*' EGD, we quantified the proportion of its range
263 within protected areas. We take into account the protected areas categories I to VI assigned by

264 the International Union for Conservation of Nature (IUCN) (Dudley, 2008) and the National
265 Parks, even though these are not included in any IUCN category. Shapefiles of the protected
266 areas were obtained from the World Database of Protected Areas (IUCN & UNEP-WCMC,
267 2020) and <http://mapas.parquesnacionales.gob.ar/>.

268

269 **Results**

270 **Systematic account**

271 Superfamily Punctoidea Morse, 1864

272 Family Charopidae Hutton, 1884

273 Subfamily Charopinae Hutton, 1884

274

275 *Stephadiscus* Hylton Scott, 1981

276 *Type species: Helix lyratus* Couthouy "in" Gould, 1846, by original designation.

277

278 **Species description** (Figs 2, 3, 4)

279 *Stephadiscus lyratus* (Couthouy "in" Gould, 1846)

280 *Helix lyrata* Couthouy "in" Gould, 1846: 167; 1852: 39.

281 *Patula rigophila* Mabille, 1886: 123.

282 *Amphidoxa lirata* Pilsbry, 1894: 41.

283 *Amphidoxa (Stephanoda) lyrata* Smith, 1905: 339

284 *Stephanoda lyrata* Pilsbry, 1911, 518; Hylton Scott, 1972: 67.

285 *Stephadiscus lyratus* Hylton Scott, 1981: 124; Miquel and Araya, 2013: 230.

286

287 *Syntype*: MCZ 88297 MCZ: Museum of Comparative Zoology, Harvard University

288 *Type locality*: Orange Harbor, Tierra del Fuego [according to Johnson (1964): located at the west
289 side of Nassau Bay].

290

291 **Morphology** (Figs 2-4)

292 *External body morphology* (Fig. 2A-B)

293 Animal black with lighter foot and mantle collar around shell aperture. A deep longitudinal

294 furrow, the pedal groove, runs parallel to the foot edge on each side and above it. Dark irregular

295 spots are seen for transparency through the shell, although some specimens are lighter. Foot
296 short, triangular pointed, not to slightly surpassing the shell diameter.

297 *Shell* (Figs. 2 C-E; 3A-E): Discoidal, 3 ½ to 4 convex regularly expanded whorls, low spire
298 depressed, not planispiral as apex elevated, fragile (DM=4,247-5,041mm; Dm=3,444 -
299 4,487mm; H= 2,283-2,432mm) with brown caramel to light whitish color (Figs. 2 A-E).

300 Protoconch with 35 - 40 axial delicate, smooth, elevated ribs separated at regular intervals (Fig.
301 3A). Spaces between protoconch ribs with thinner axial costulae. Protoconch not clearly
302 delimited from the teleoconch, and similarly sculptured. Teleoconch surface with major axial
303 ribs (Figs. 3B-D), interspace between them of 4-7 µm filled with 5 to 7 micro radial costulas in
304 between major ribs, nodules at regular intervals supporting ribs, giving the appearance of radial
305 cords (Figs. 3B-C). Deep irregular suture (Fig. 3D). Circular aperture, not descendent, with sharp
306 peristome (Hap=1,861-2,110; Dap= 1,809-1,998). Umbilicus 1/3 or slightly less of body whorl
307 major diameter, with same sculpture as nepionic portion of the shell (Fig. 3E).

308 *Pallial system* (Fig. 4A): Pulmonary roof dark with black spots and whitish small granules over
309 the surface. Spots and granules visible through shell. Pulmonary sac short occupying 1/4 of body
310 whorl. Kidney triangular, bilobated, with pericardial side lobe overlapping pericardium. Rectal
311 side kidney lobe bigger than pericardial arm. Principal pulmonary vein short, slender, not
312 branched, smoothly marked. Remaining pulmonary roof smooth with no other veins. Secondary
313 ureter present, close along its length, parallel to rectum. Pallial gland absent.

314 *Jaw and radula*: Jaw consist on narrow vertical plates, slightly arched, cream colored. Radula as
315 described by Hylton Scott (1970).

316 *Reproductive system* (Figs. 4B-E): Albumen gland shapeless, roughly globular, rounded margins.
317 Spermooviduct formed by prostate and uterus fused together. Uterus divided in two portions,
318 proximal short, cylindrical, continuous to albumen gland, distal expanded in rounded glandular
319 chamber (Figs. 4B, C). Free oviduct cylindrical, short. Bursa copulatrix sac round, resting over
320 uterus distal portion. Duct of bursa copulatrix basally thickened, progressively decreasing in
321 diameter towards the sac (Fig. 4D). Vagina as long as bursa copulatrix duct, distally widened,
322 featuring three thick, longitudinal pilasters on the interior wall. Vas deferens cylindrical, narrow
323 in diameter, short, running from basal prostate towards peni-oviducal angle, inserting into
324 epiphallus. Penial retractor thin, inserted in penis. Penis cylindrical, thicker than epiphallus, with
325 a sac-like appendix in upper portion (Fig. 4C-E). Short verge in upper penial chamber, inner

326 penial wall with short pilaster noticeable towards middle penis length. Epiphallus reflected over
327 penis, shorter, thinner ending in a short finger-like flagellum (Fig. 4E). Vas deference delated
328 before inserting into epiphallus anteriorly of penial retractor insertion, dilatation as long as
329 flagellum, giving appearance of fork ending epiphallus.

330

331 **Microhabitat characterization**

332 Rainforests provide a variety of living spaces where snails can feed, crawl, and live. Although
333 micro snails are usually associated with leaf litter, *Stephadiscus lyratus* was mainly found living
334 on or under the bark of fallen trees or under humid logs in contact with the ground (Figs. 1C, D).
335 We found actively crawling snails only on tree barks or on moss logs. This species is not
336 considered to be arboreal or semi-arboreal. No specimens were found in living trees, nor in their
337 leaves or shrubs, the majority of alive snails were found under fallen decaying logs in contact
338 with the ground. During the hibernation period in wintertime, these microhabitats in contact with
339 soil can act as a buffer and help the species to survive during extreme freezing conditions. Dry
340 shells were recovered from soil samples, but in general, they were worn out. Feeding habits are
341 not known, but probably are associated to a diversity of fungi from the decaying wood, an
342 important food resource for snails. Species of the genus *Radiodiscus* occur in sympatry with *S.*
343 *lyratus*. In places outside protected areas where the forest shows some degree of alteration, living
344 snails were scarce or difficult to find.

345

346 **Species Remarks**

347 The history of the species discovery as well as the problem of the species authorship are
348 explained in Supplementary Material (See Appendix).

349

350 *Comparison with species of the same genus:* *S. lyratus* has the largest shell diameter (DM= 5.5
351 mm) among all species classified in *Stephadiscus*. It is a very conspicuous species regarding its
352 shell coloration and sculpture. Although *S. perversus* is similar in shell coloration, it cannot be
353 confused with *S. lyratus* because it is sinistrorse and has a smaller shell (DM=2, 8; H= 1.5mm).
354 *S. lyratus* is also similar in shell sculpture and general shape to *S. stuardoi* (DM= 2.0-2.02, H=
355 0.85), but clearly differs from this species in its larger shell diameter and the absence of weak
356 spiral threads in the teleoconch. In the original description, Couthouy in Gould mentioned that *S.*

357 *lyratus* could be a synonym of *Helix costellata* d'Orbigny, 1835 (now *Zilchogyra costellata*
358 (d'Orbigny, 1835)). However, *H. costellata* is distributed in the Humid Pampa ecoregion in
359 Buenos Aires, Argentina, an extra Patagonian area with completely different ecological
360 requirements. *H. costellata* (DM=4 mm, H= 2 mm) is smaller in shell diameter and height than
361 *S. lyratus* and its protoconch is a smooth surface.

362 *Stephadiscus lyrata* and *S. mirabilis* are the only species of the genus with known anatomies.
363 Both show a rounded glandular mass, identified as a "dilated sac" by Hylton Scott (1970) at the
364 base of the spermiduct, in the distal genitalia. A similar structure is also present in
365 *Stephacharopa testalba* (Hylton Scott, 1970). Most of the described species of the genus have
366 been originally established only on single or two dry shells (Table S2), and after their discovery,
367 rarely fresh specimens have been collected in their area of distribution.

368

369 *Comparison with related genera:* *Stephadiscus* is defined by having plane-convex whorls,
370 presence of a protoconch, and teleoconch with similar ornamentation consisting of thin, nodulose
371 ribs, without a marked limit between the protoconch and the teleoconch (Hylton Scott, 1981;
372 Miquel & Araya, 2013). Therefore, the transition of protoconch towards teleoconch is barely
373 distinguished. These ribs increase in height towards the body whorl, with thinner costula in the
374 interspaces. *Stephadiscus* is different from *Stephacharopa* Miquel & Araya, 2013 because in the
375 latter genus, the sculptured protoconch is dissimilar to the teleoconch ornamentation while in the
376 former, the sculptured protoconch is similar to the one present in the teleoconch. *Stephadiscus*
377 differs from *Stephanoda* mainly in the sculpture of the protoconch, since the latter possesses a
378 reticulated pattern. Differences in anatomy are not possible to be established for the lack of
379 studies on these genera. Other South American charopid genera, such as
380 *Lilloiconcha* Weyrauch, 1965 and *Zylchogyra* Weyrauch, 1965 can reach similar shell sizes but
381 differ from *Stephadiscus* in general shell shape and in that their protoconch is smooth (Miquel &
382 Araya, 2013). *S. lyratus* shows a specialized vas deferens-epiphallus junction as other
383 Charopinae from the Pacific Islands described by Solem (1982), marking a difference with
384 subfamilies Semperdoninae, Trukcharopinae, and Rotadiscinae.

385

386 **Estimations of potential geographic distributions (EGDs)**

387 We obtained 24 candidate models statistically significantly better than null expectations (i.e.,
388 predictions from the models coincided with testing occurrence data more frequently than would
389 be expected by random association of points and a prediction of that areal extent) (Table S3).
390 From these, only one final model was selected that was statistically significant and met the AICc
391 criteria (two of three selection criteria) (Table S4). The chosen settings were linear, quadratic,
392 and product features and 0.1 of regularization multiplier. The bioclimatic variables that most
393 contribute to the model were BIO3 = Isothermality (BIO2/BIO7) ($\times 100$), BIO12 = Annual
394 Precipitation, BIO6 = Minimum Temperature of Coldest Month, and BIO4 = Temperature
395 Seasonality (standard deviation of mean month temperature * 100) (47%, 17%, 12% and 11.5%
396 percent of contribution, respectively). Response curves also gave an indication of the range
397 under which the variable reaches its optimum suitability. BIO3 quantifies how large the daily
398 temperature fluctuations are relative to annual oscillations. A value of 100 indicates that diurnal
399 temperature range is the same as the annual temperature range, while lower values indicate that
400 day to night temperature oscillations are smaller than annual temperature fluctuations
401 (O'Donnell & Ignizio, 2012). The optimum of suitability for isothermality is around 43% to
402 55%, from here decreased abruptly to zero (Fig. 5A). BIO4, BIO6 and BIO12 displayed a bell-
403 shaped response of increased suitability as the variable increases above a certain value (Fig. 5B-
404 D). The optimum suitability of BIO4 is around 2750, this is a measure of temperature change
405 over the course of the year, the larger the value (standard deviation of mean monthly temperature
406 $\times 100$), the greater the variability of temperature (O'Donnell & Ignizio, 2012). The optimum
407 suitability of BIO6 is between -2 and 0 °C (around -1°C, Fig. 5C), this is a measure of minimum
408 cold temperatures through the year. In the case of BIO12 the species had its maximum suitability
409 in the 500–600 mm within a narrow range that abruptly decreased when the precipitation
410 increased above this threshold (Fig. 5D).

411

412 **Spatial analysis**

413 The known area of distribution of *S. lyratus* was approximately 72,672 km², mainly coincident in
414 the southern portion of the Magellanic Subpolar Forest (below -51° of latitude), at both sides of
415 the Andes and marginally in the southern part of Patagonian steppe in Tierra del Fuego (Fig.
416 6A). The MOP analysis (Fig. S1) indicated that areas with the most dissimilar variables
417 conditions (i.e., where one or more environmental variables are outside the range present in the

418 training data) were found beyond the potential distributional areas predicted by the model in the
419 “G” area.

420 When the final model is transferred to region "G", we found that the potential area of distribution
421 almost duplicates their original range (140,454 Km²). This new region extends mainly to the
422 Valdivian Temperate Forest between –40 and –46 latitude, mostly in Chile and a small portion of
423 the Argentina, while towards the Patagonian steppe increase marginally (Fig.6B).

424 Natural and semi-natural terrestrial vegetation was predominant in the occurrence points and in
425 the potential area of distribution of *S. lyratus*. The occurrences points overlap a 33% and the
426 EGD a 48% with woody trees (closed to open (>15%) broadleaved evergreen or semi-deciduous
427 forest (>5m)), while the overlap with shrub (closed to open (>15%) (broadleaved or needle-
428 leaved, evergreen or deciduous shrubland) was a 31% and 21%, respectively (Table 1).

429 The proportion of the potential distribution area in protected areas was 14.7%, occurring in 16
430 protected areas, from which six of them are located in Argentina while the remaining are from
431 Chile. The higher proportional area protected is due to National Parks “Alberto D'Agostini” and
432 “Yendegaia” (Chile), and Multiple Use Provincial Reserve “Corazon de la Isla Tierra del Fuego
433 (Argentina). Taking into account the category of management of IUCN, nine are category II
434 National Parks and Ib Wilderness Nature Reserve; the six remaining are category IV Forest
435 Reserve and VI Multiple Use Provincial Reserve (Table 2).

436

437 **Discussion**

438 *Taxonomy and Species Morphology*

439 Features of the gastropod shell have always been an essential and convenient source of
440 taxonomic information. However, it is well recognized that shell characters such as shape,
441 coiling patterns, and ribbing can be convergent and often mask crucial differences in anatomy
442 (Stanisic, 1990; Barker, 2001). Hylton Scott, understanding the value of anatomical information,
443 was the only researcher to provide anatomical descriptions of some South American charopids
444 such as *Stephacharopa testalba*, *Stephadiscus lyratus*, *S. mirabilis*, *Zilchogyra leptotera*
445 (Mabille, 1886). Recently, a study on Punctoidea phylogeny provided molecular information on
446 some charopid species (Salvador et al., 2020). *Stephadiscus lyratus*, as all the species of the
447 genus, has similar ornamentation in the shell protoconch and in the teleoconch, without a
448 marked limit between them. The type of ornamentation and similitude between protoconch and

449 teleoconch differences *Stephadiscus* from all other South American charopid genera (Miquel &
450 Cádiz Lorca, 2008; Miquel & Barker, 2009; Miquel & Araya, 2013). Anatomical information
451 provided proves to be an essential source of characters relevant for future taxonomic and
452 phylogenetic studies. The presence of a be-lobed kidney with the rectal side lobe bigger than the
453 pericardial portion, plus the presence of a close secondary ureter, clearly indicate that *S. lyratus*
454 belongs to Charopidae, differencing it from the Endodontidae. Solem (1982) raised these
455 characters as the main differences between both families. The terminal portion of the uterus
456 (spermoviduct), forming a compact glandular mass, is also a striking character that has only been
457 mentioned before for *Stephacharopa testalba*. Along with this, the insertion of the vas deferens
458 into the epiphallus through a dilatation constitutes unique structures of *S. lyratus*.

459

460 *Estimation of the potential geographical distribution (EGD) and spatial analysis.*

461 The new records obtained were associated with native areas of the Magellanic Subpolar Forest
462 sub-ecoregion in Argentina. The transferred model shows a potential distribution of *S. lyratus* to
463 the Valdivian Temperate Forest, spreading the known area to a new sub-ecoregion,
464 corresponding mainly to the area of this mentioned zone in Chile. Although, no specimens of *S.*
465 *lyratus* have been found in the Valdivian forest areas in Argentina (Nahuel Huapi and Los
466 Alerces National Parks), these surveyed areas are outside to the east of the potential area
467 predicted by the model. Thus, the potential area of distribution of *S. lyratus* is coincident with the
468 Magellanic Subpolar Forest and the Valdivian Temperate Forest (more towards Chile) together
469 with its boundaries with the Patagonian Steppe ecoregion. The obtained hypothesis of the
470 potential distribution of *S. lyratus* will direct the next exploratory surveys with the expectation to
471 find new populations in the future.

472 The biogeographic Valdivian Forest province according to Kuschel (1960) and Morrone (2018)
473 has faunistic relationships with Magellanic Forests, probably due to the fact that both regions
474 have been isolated from other South American forests since the Neogene (Axelrod, Kalin Arroyo
475 & Raven, 1991). In addition, the cooling cycles followed by warmer periods in the Quaternary
476 caused the contractions and expansions of the temperate forests (Villagrán & Hinojosa, 1997),
477 and some areas in the coastal range remained free of ices and may have been the source for the
478 recovery of the forest biota (Smith, 2017).

479 From the seven environmental variables used in the EGD analysis of *S. lyratus*, the main
480 constraining variables are the temperature (Isothermality, Minimum Temperature of Coldest
481 Month, and Temperature Seasonality) and Annual Precipitation.
482 Other studies using native snails in South America that analyzed the role of abiotic factors in
483 relation to their distribution are scarce e.g., the case of *Megalobulimus sanctipauli* (Ihering &
484 Pilsbry, 1900). This kind of studies for native micro snails are virtually nonexistent.
485 *Megalobulimus sanctipauli*, known to inhabit the Atlantic Forest, showed temperature and
486 rainfall as the determinant factors of their geographic distribution (Beltramino et al., 2015). In
487 the case of *Achatina fulica* Bowdich, 1822, an exotic land gastropod in South America,
488 Temperature Seasonality, and Mean Temperature of the coldest quarter were the variables that
489 contribute the most to the model when they were used alone (Vogler et al., 2013). In the case of
490 *S. lyratus*, the bell shape of environmental suitability for the Minimum Temperature of Coldest
491 Month, Seasonality Temperature and Annual Precipitation apparently show that the studied
492 species try to avoid extreme temperature and precipitations oscillations. The minimum
493 temperature of the coldest month shows predicted suitable conditions at sub-zero temperatures. It
494 suggests that this climatic variable is relevant for its optimal growing conditions and in particular
495 in relation to the species winter survival. Indeed, *S. lyratus* is found in the Magellanic Subpolar
496 Forest where winter temperatures can drop below 0°C. Empirical data on the life history of small
497 land snail species in their natural habitat are hardly available worldwide. There are also very few
498 data on gastropod cold hardiness, especially on land snail species of small sizes. Ansart &
499 Vernon (2003) sustained that two alternatives exist for organisms living in areas that freeze in
500 winter, such as the southern forest in Patagonia: move to an unfrozen habitat or face freezing
501 conditions. For this last category, avoid freezing by extensive supercooling (freezing avoidance)
502 or survive freezing of the body fluids (freezing tolerance) are the only possibilities. Freezing
503 avoidance, involves the choice of a hibernation site, which buffers the temperature differences,
504 and which permits avoidance of inoculative freezing (e.g., by contact with ice). During
505 hibernation, the snails rapidly suppress their metabolism and minimize water loss using a
506 discontinuous gas-exchange pattern (Košťál et al., 2013). We sustain that *S. lyratus* find
507 favorable overwintering microhabitat in soil, under tree bark or under fallen tree trunks in
508 contact with soil, which is well buffered from temperature and moisture fluctuations allowing the
509 species to survive during winter freezing.

510 Decaying wood can absorb and retain water for several weeks during periods of low
511 precipitation, providing a buffer from microclimate extremes (Jordan & Hoffman Black, 2012).
512 Land gastropods require moisture for respiration and locomotion, and humid microenvironments
513 are known to be a prerequisite for the occurrence of many land mollusk species. However,
514 excessive wet extremes that lead to flooded soils for long periods are not tolerated by most micro
515 snail species that buried in the soil. This can be a restrictive situation to *Stephadiscus lyratus*
516 occurrence as it is showed by the predicted environmental suitability in a narrow range of annual
517 precipitation not surpassing around 1500 mm per year. Also, this would explain the occurrence
518 of *S. lyratus* in humid areas of Magellanic subpolar forest, and the projected potential
519 environments in some regions of northern Valdivian Temperate Forest, which featured by 1000
520 mm of precipitation per year (<https://www.worldwildlife.org/ecoregions/nt0404>).

521

522 *Stephadiscus lyratus*, a vulnerable species to protect

523 *Stephadiscus lyratus* inhabit mostly woody areas of native forests. The preferred microhabitats of
524 the species are sites on or under the bark of fallen trees or under humid logs in contact with the
525 soil. These microhabitats are less frequent in disturbed forest areas with high human pressure
526 located in Tierra del Fuego outside the National Park, where specimens were difficult to find
527 alive. In addition to microclimate effects, coarse woody debris has a significant influence on
528 gastropod food availability. Dead and decaying wood promote a diversity of fungi, an important
529 food resource for many snails

530 Land gastropods are suffering habitat loss and competition from introduced species (more
531 numerous and prolific every year), although are regarded as non-charismatic groups for
532 conservation purposes (Régnier et al., 2009; 2015). In the case of Orthalicoidean land snail in
533 Argentina, only 3% of their average species distribution ranges are safeguarded within current
534 protected areas, showing that the existing protected areas system is not effective at all for the
535 protection of this invertebrate group (Ovando et al., 2019). In the present study, we found that
536 14,5 % from a total current distributional area of 72,672 km² of *S. lyratus* is inside the system of
537 protected areas. However, it is important to emphasize the threats and pressures of land-use
538 change such as tourism, logging and frequent fires that compromise not only areas inside the
539 southern National Parks but also the matrix that surrounds them. In fact, 700–1000 ha are logged
540 each year (from 1980 to 2003) in Argentina, Tierra del Fuego (Gea-Izquierdo et al., 2004). In

541 addition, extensive livestock holdings, aquaculture, and tourism are advancing into formerly
542 undisturbed areas. In the Chilean Magellanic forests between 53.1 % and 68.1 % of this land is
543 influenced by human activity in some way (Inostroza, Zasada & König, 2016). In this context,
544 habitat loss for land gastropod conservation is very worrying. Moreover, the protected areas in
545 Argentina were created for the protection of plants (Ortega-Baes et al., 2012) and/or vertebrates
546 (Tabeni, Bender & Ojeda, 2004; Arzamendia & Giraud, 2004; Corbalán et al., 2011; Tognelli et
547 al., 2011), ignoring the invertebrates even when their importance has been proven (Chehébar et
548 al., 2013). This situation is a worldwide problem since there are more than a million invertebrate
549 described species but only 3,500 are protected (Baillie, Hilton-Taylor & Stuart, 2004; Brooks et
550 al., 2004, 2006; Nieto et al., 2017). We sustain that *S. lyratus* find favorable overwintering
551 microhabitat in soil or under stones in contact with soil, which is well buffered from temperature
552 and moisture fluctuations allowing them to survive during winter freezing.

553 The combination of the ectothermic traits of this species, low dispersal capacity, probable low
554 fecundity producing only few eggs, and its narrow habitat requirements (forest specialist) turns
555 *S. lyratus* into a vulnerable species. Along with habitat loss through human land use, climate
556 change is a major contributor to biodiversity loss in the 21st century (Lee et al., 2015). However,
557 terrestrial gastropods have so far received little attention regarding the potential impact of current
558 rapid climate change on their distribution, compared with other taxa (Lee et al., 2015).

559 The climate is changing rapidly, and terrestrial ectotherms are expected to be particularly
560 vulnerable to an increase in extreme weather events in temperate regions (Nicolai & Ansart,
561 2017). They will be affected seasonality by more frequent hot temperature extremes and fewer
562 cold temperature extremes over most land areas (IPCC, 2014). Meanwhile, the projected
563 precipitation changes show reductions for the dry area in the central-western region and for the
564 whole of Patagonia (Barros et al., 2015). In the Magellanean region, there have been reported
565 extreme events that could be increase in frequency and intensity in the context of climate change.
566 Examples of these events were severe droughts (1920–1926, 1928, 1966), heavy rainfall events
567 with floods (1983, 1990, 2012, 2015), and devastating snowfall storms. Thus, the quality and
568 availability of habitat for *S. lyratus* could be compromised by the effect of both land uses
569 changes and global warming. In this context, these regional changes in climate and land use put
570 *S. lyratus* populations at serious risk of extinction that must be taken into consideration for future
571 conservation actions.

572

573 **Conclusions**

574 1. Here we confirm that the shell ultrastructure of *S. lyratus* has a protoconch and teleoconch
575 with similar ornamentation, not showing a marked limit between them. We provide new
576 anatomical information highlighting the presence of a be-lobed kidney, a close secondary ureter,
577 and the terminal portion of the uterus (spermoviduct) forming a compact glandular mass, the vas
578 deferens inserting into the epiphallus through a dilatation as the most notable anatomical
579 characters of *S. lyratus*.

580 2. The potential distribution obtained shows that *S. lyratus* could be found beyond the
581 Magellanic Subpolar Forests into the Valdivian Temperate Forest, which would increase its
582 known distribution area to a new sub-ecoregion, mainly within Chile.

583 3. From seven environmental abiotic variables used, the main constraining ones to explain *S.*
584 *lyratus* occurrence in the EGD are the temperature (Isothermality, Minimum Temperature of
585 Coldest Month, and Temperature Seasonality) and Annual Precipitation.

586 4. *Stephadiscus lyratus* inhabits cold native forest areas where it is found mainly on or under the
587 bark of fallen trees or under damp trunks in contact with the ground. This microhabitat allows
588 them overwintering, buffered from temperature and moisture fluctuations, and survive during
589 winter, probably as a strategy to avoid freezing.

590 5. The combination of the ectothermic physiological traits of this species, low dispersal capacity,
591 and its narrow habitat requirements (forest specialist) turns *S. lyratus* into a vulnerable species,
592 not only because of current land-use change but also to climate change.

593

594 **Acknowledgement**

595 We would like to thank the curators and researchers from the different collections and databases
596 consulted, Alejandro Tablado and Sergio Miquel (MACN-In); Gustavo Darrigran (MLP);
597 (NMNH); Museum of Comparative Zoology (MCZ) and Academy of Natural Sciences in
598 Philadelphia (ANSP). To the National Parks agency of Argentina for providing permits to work
599 in Tierra del Fuego, Los Alerces, and Nahuel Huapi National Parks. A special thanks to the Los
600 Alerces park rangers, Florencia Pantasso, and Dario Bassoso, who kindly support and facilitate

601 all fieldwork. MGC would like to thank the Centro Austral de Investigaciones Científicas
602 (CADIC-CONICET) for allowing us to use their facilities during December 2018 and January
603 2019 for this research. A special thanks to Christopher Anderson, who kindly offered space in
604 his laboratory and helped to obtain all permits to work in Tierra del Fuego. To Marina
605 Tagliaferro for her kindness and support in the CADIC microscopy laboratory. To Christopher
606 Anderson and Alejandro Valenzuela for their kind hospitality while in Ushuaia. To A. Lira-
607 Noriega and L. Osorio-Olvera for teaching and supporting us with the methodology and use of
608 the Kuenm package for R.

Figure 1

Study area and collection points of *Stephadiscus lyratus*.

(A) Magellanic Subpolar Forest, Valdivian Temperate Forest and Patagonian steppe sub ecoregions showing historic records of occurrence. **(B)** Southern portion of Tierra del Fuego with new records of occurrences. **(C) (D)** Aspect of the Magellanic subpolar forest trees, mainly corresponding to the genus *Nothofagus*, where the studied species was collected.

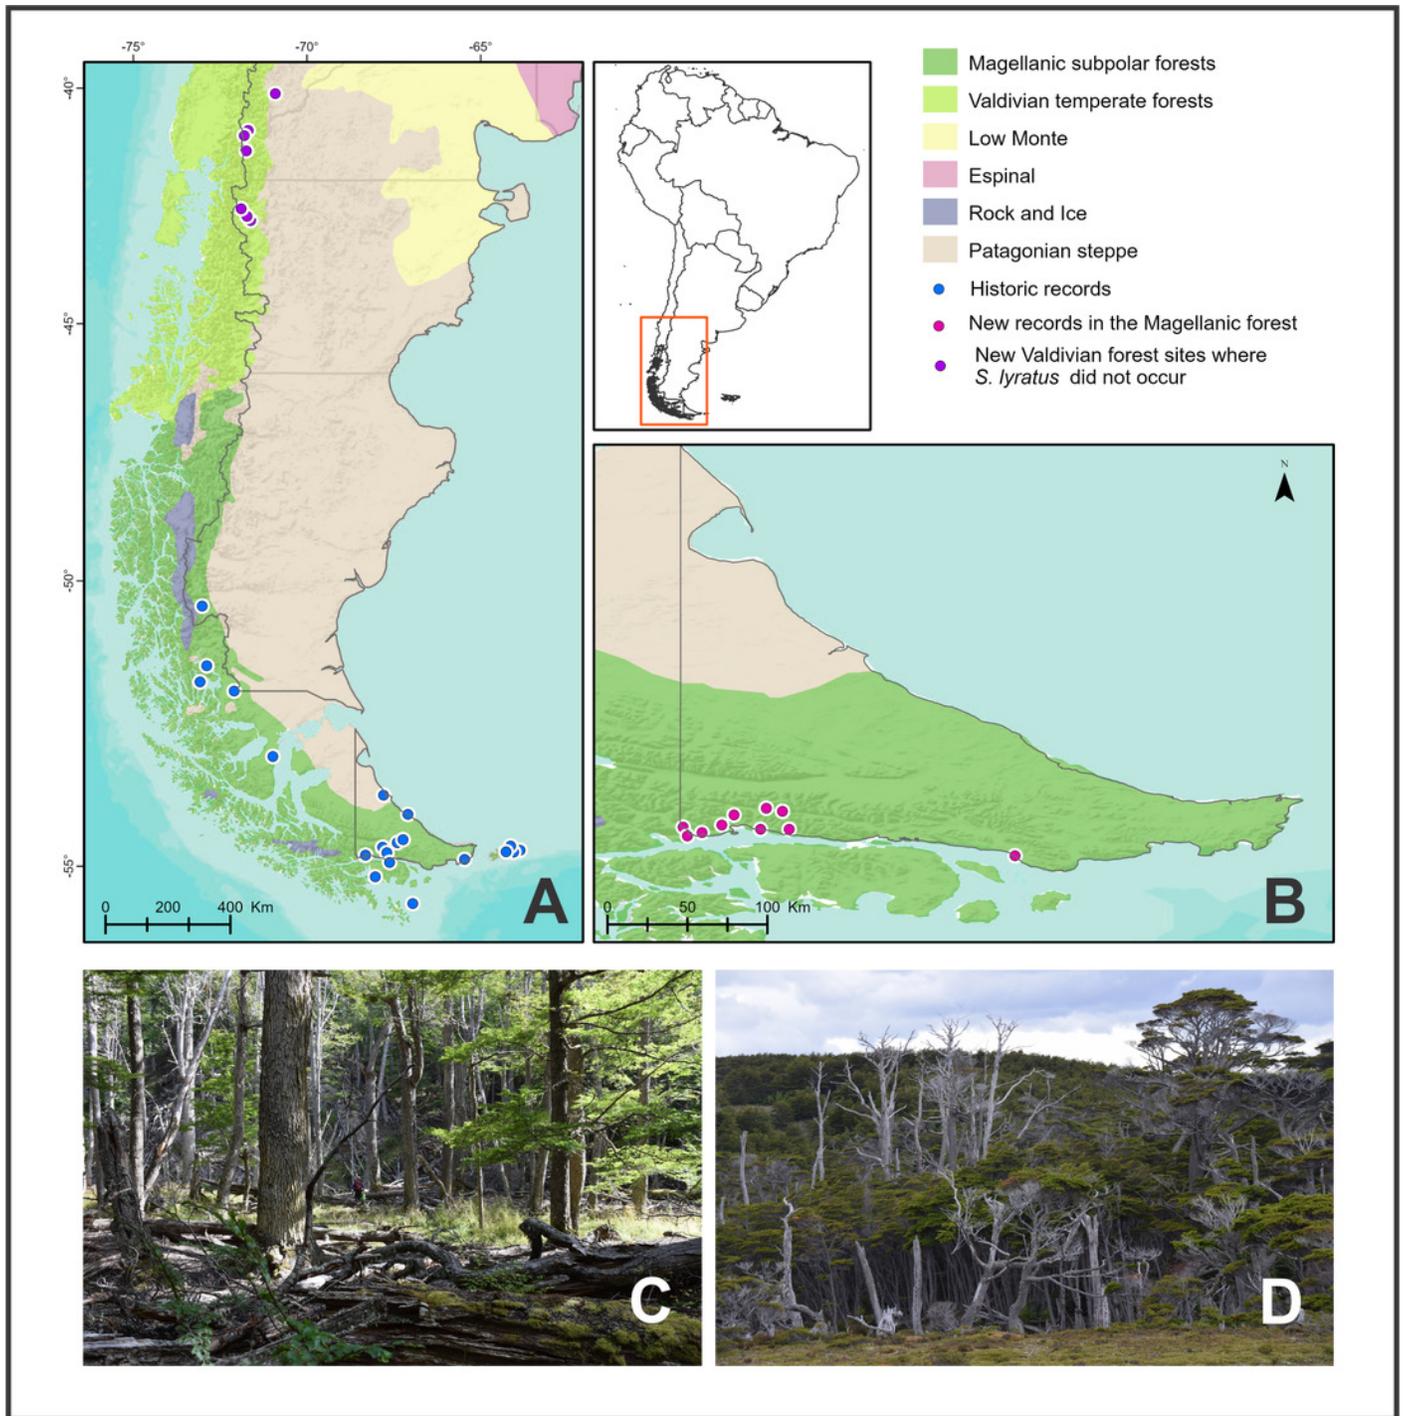

Figure 2

External morphology of *Stephadiscus lyratus* shell and live animal.

(A) (B) Live animal from Tierra del Fuego National Park showing natural shell coloration and by transparency, the irregular spots of the lung. Note black animal body with lighter basal foot and mantle collar. (C) Dorsal, (D) ventral and (E) lateral views of shell, scale bar= 1mm (IBN 951). Photo credit: MG Cuezzo.

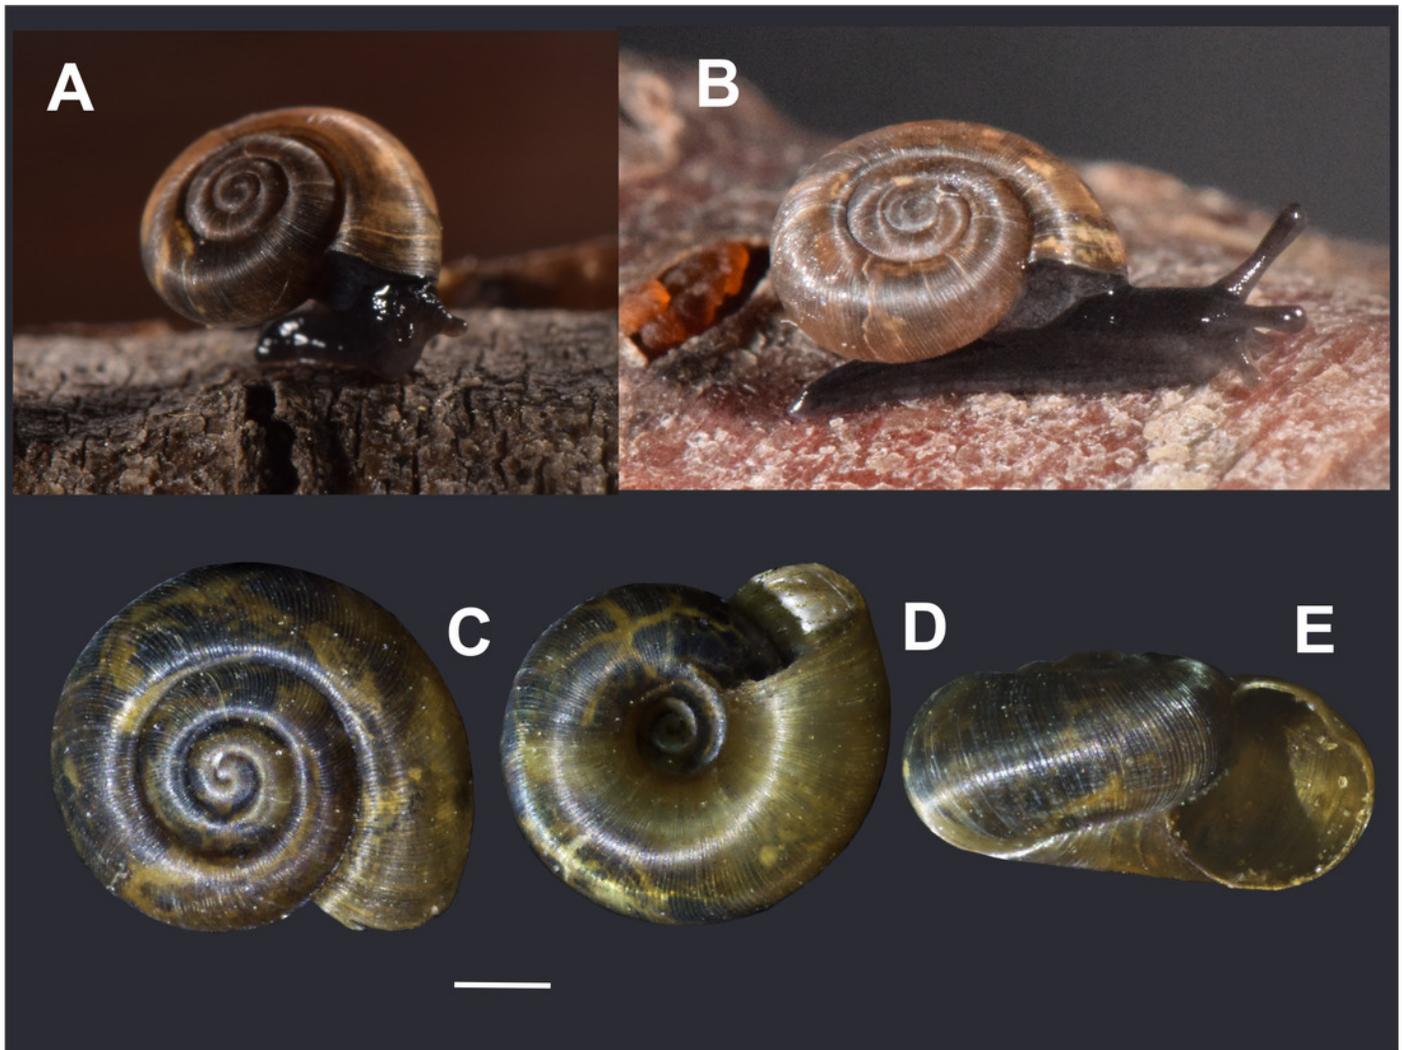

Figure 3

Shell ultrastructure of *Stephadiscus lyratus*.

(A) Ultrastructure of protoconch showing the radial disposition of major ribs, scale bar= 100 μm . (B) (C) details of the body whorl sculpture with major ribs separated at regular spaces, and micro radial ribs. Note nodules supporting ribs, scale bar= 10 μm . (D) Deep suture between body whorls and penultimate whorl, scale bar= 10 μm . (E) Shell umbilicus with sculpture, scale bar=20 μm . Photo credit: MG Cuezco.

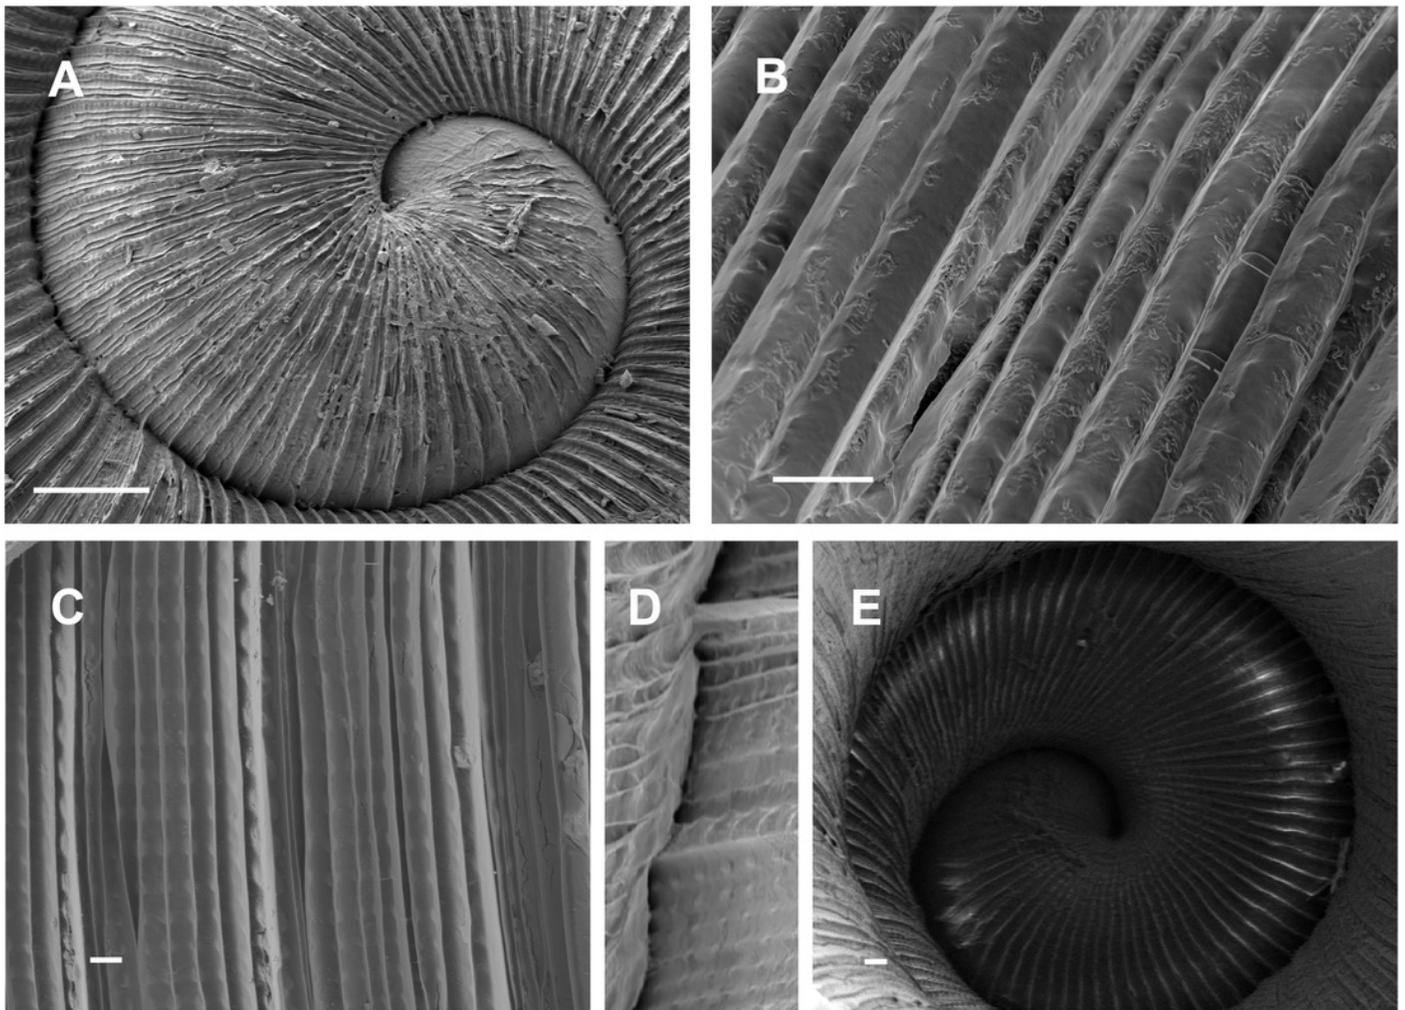

Figure 4

Morphology of pallial and reproductive systems of *Stephadiscus lyratus*.

(A) Pallial system with pulmonary and pericardial cavity. Note the beloved kidney overlapping the pericardium. Small whitish concretion are scatter along the pulmonary roof. (B) General shape of reproductive system showing large, rounded albumen gland and spermooviduct divided in two portions, proximal short, cylindrical, continuous to albumen gland, distal expanded in rounded glandular chamber, scale bar= two mm. (C) Detail of the uterus chamber in distal spermooviduct, free oviduct cylindrical, short, scale bar= two mm. (D) Duct of bursa copulatrix with basal widening, sac rounded. (E) Detail of the penial complex showing penis with a sac-like appendix. The epiphallus reflected over penis, is continuous with a short finger-like flagellum. Note that the vas deferens is dilated before inserting into epiphallus and that the dilatation is as long as the flagellum, giving appearance of fork ending epiphallus, scale bar= two mm. Abbreviations: ag, albumen gland; bc, bursa copulatrix; dbc, bursa copulatrix duct; e, epiphallus; f, flagellum; fo, free oviduct; hd, hermaphroditic duct; kl1, pericardial side kidney lobe; kl2, rectal side kidney lobe; mc, mantle collar; p, penis, pr, penial retractor; r, rectum; s, Spermoviduct; su, secondary ureter; u, uterus; v, vagina; vd, vas deferens.

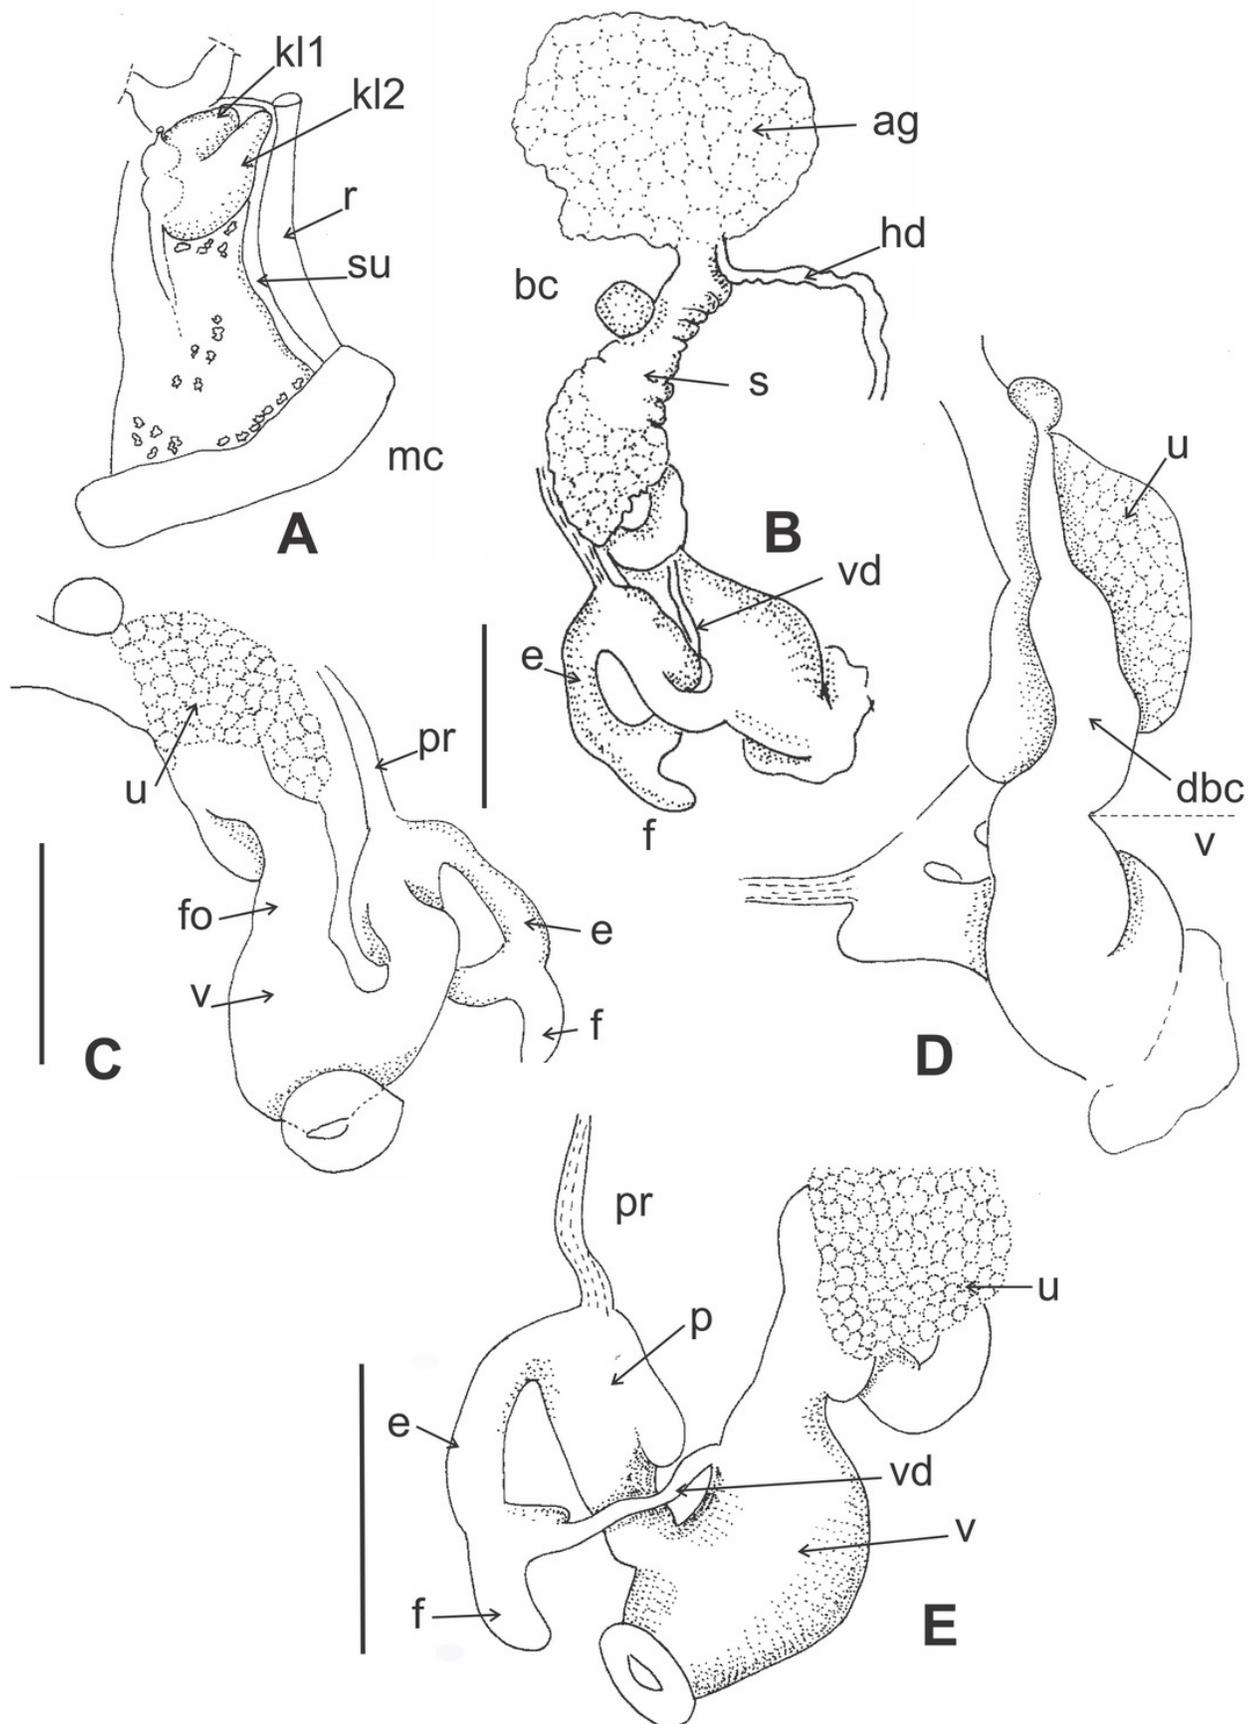

Figure 5

Response curves for the most important variables in the Maxent model for the environmental suitability of *Stephadiscus lyratus*.

(A) BIO3: Isothermality, (B) BIO4: Seasonality, (C) BIO6: Minimum temperature of the coldest month, and (D) BIO12: Annual precipitation. The red lines indicate the mean values, while blue areas denote 1 standard deviation limits, resulting from bootstrap replicates in model runs.

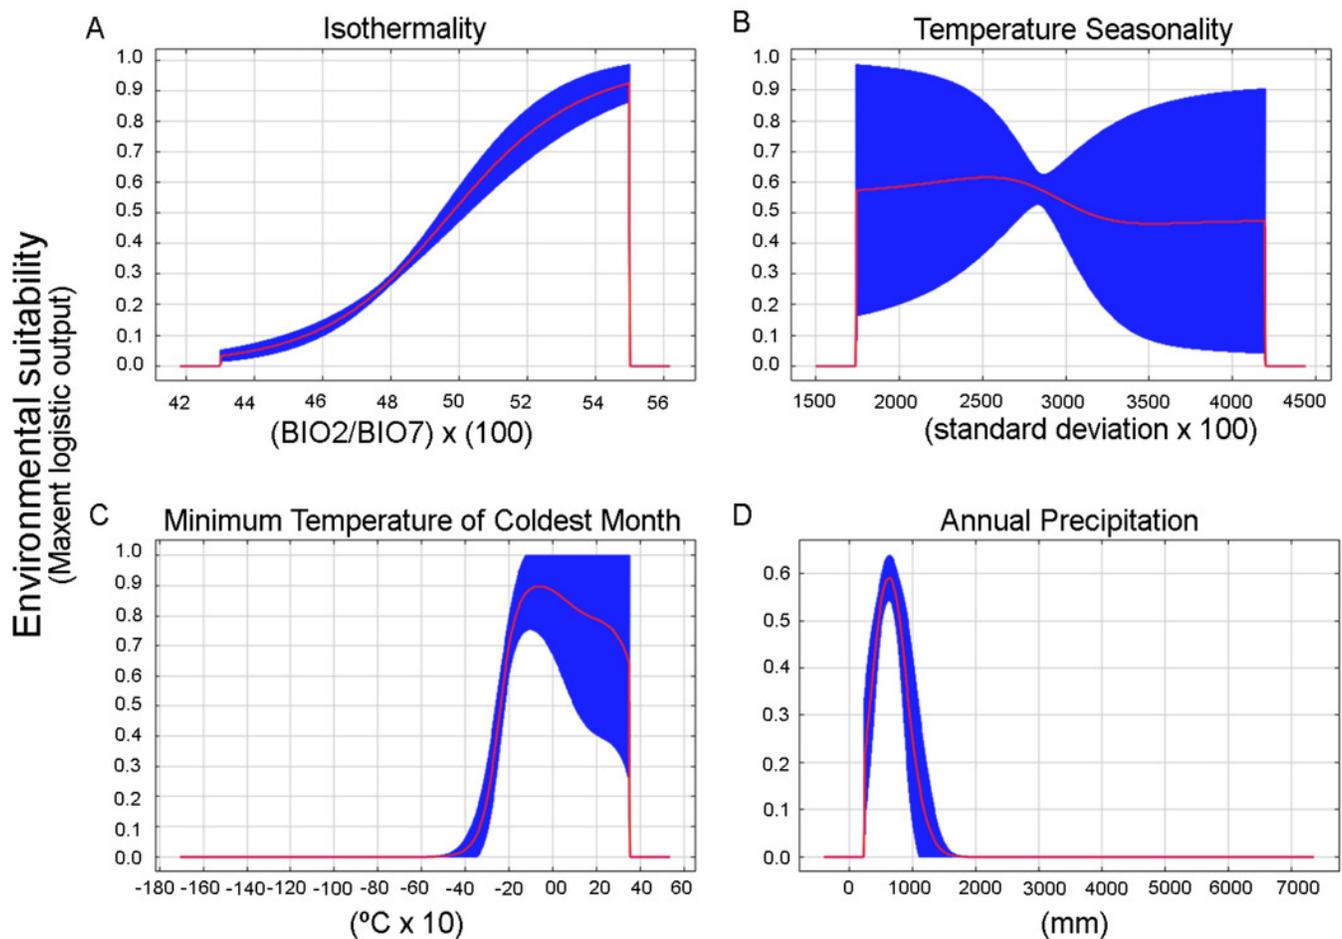

Figure 6

Estimated and Potential areas of occurrence of *Stephadiscus lyratus*

(A) Valdivian Temperate Forest and Magellanic Subpolar Forest sub ecoregions, showing "M" area and the estimated geographic distribution (EGD). (B) Final model transferred to region "G", with the potential area of distribution of *Stephadiscus lyratus*. Note that areas of the model coincident with the Valdivian Temperate Forest mostly occur in the Chilean portion of the sub ecoregion.

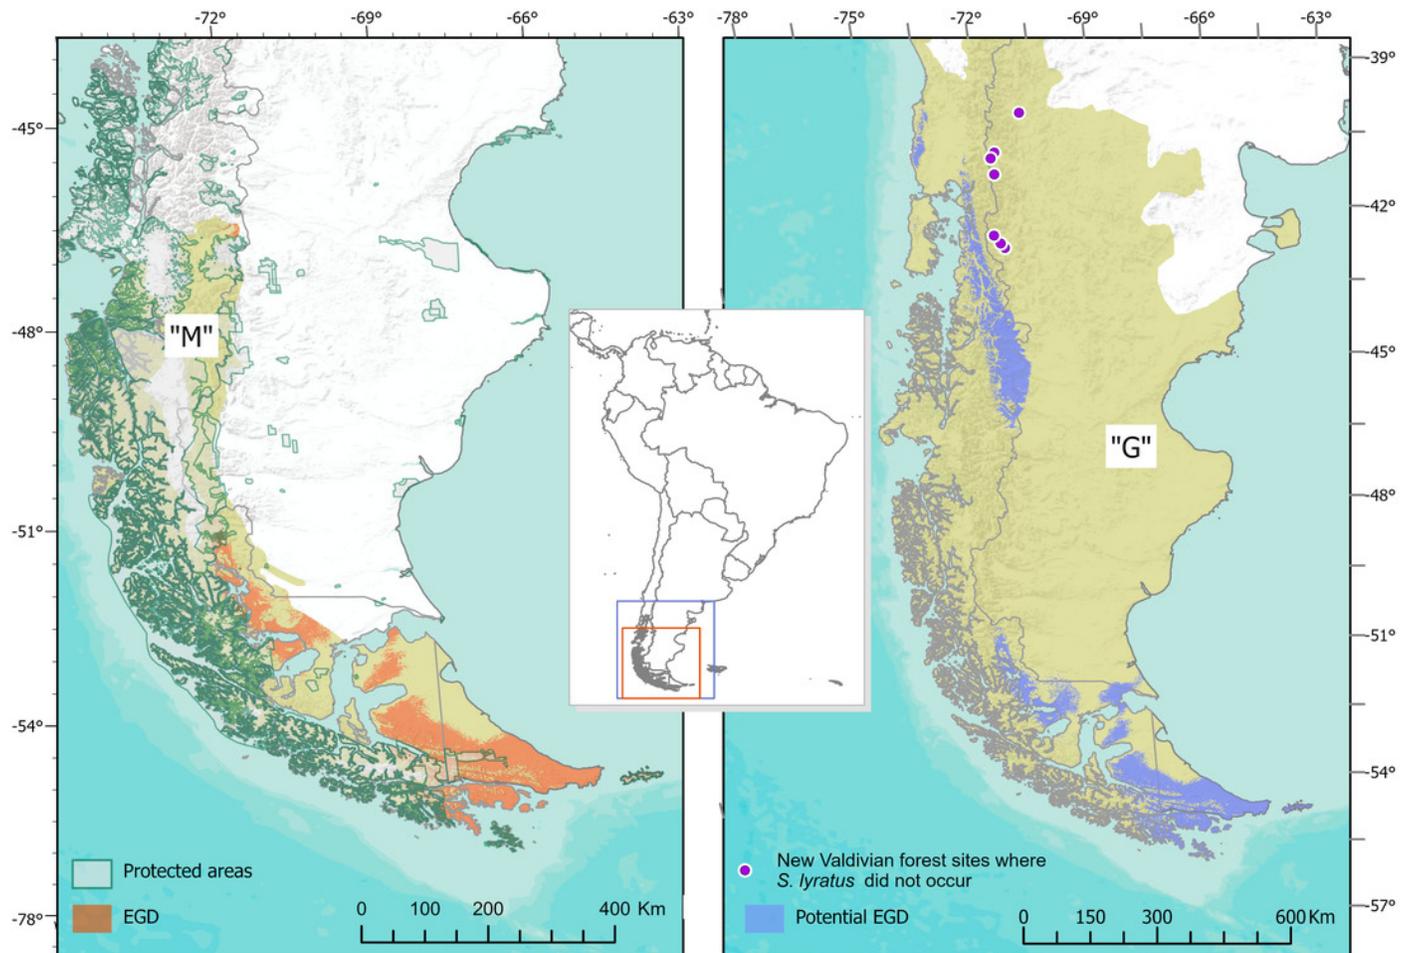

Table 1 (on next page)

Percentages of overlap of the distribution model of *Stephadiscus lyratus* and occurrence points with land cover categories from Globcover 2009 dataset (UCLouvain & ESA Team).

1

Landcover	Overlapping (%)	
	EGD	Ocurrences
Closed to open (>15%) broadleaved evergreen or semi-deciduous forest (>5m)	48.67	33.33
Closed to open (>15%) (broadleaved or needleleaved, evergreen or deciduous) shrubland (<5m)	21.04	30.77
Closed (>40%) broadleaved deciduous forest (>5m)	5.77	0.00
Closed to open (>15%) herbaceous vegetation (grassland, savannas or lichens/mosses)	4.41	12.82
Mosaic cropland (50-70%) / vegetation (grassland/shrubland/forest) (20-50%)	2.66	0.00
Mosaic vegetation (grassland/shrubland/forest) (50-70%) / cropland (20-50%)	2.02	5.13
Rainfed croplands	1.95	0.00
Open (15-40%) broadleaved deciduous forest/woodland (>5m)	1.75	2.56
Water bodies and Others	11.72	15.38

2

Table 2 (on next page)

Protected areas overlapped with distribution model of *S. lyratus*. Names, IUCN categories, country of origin and number of *S. lyratus* EGD pixels within protected areas.

NAME OF PROTECTED AREA	DESIGN TYPE	IUCN CATEGOR Y	COUNT RY	PIXELS (N°)
Alberto D'Agostini	National Park	II	Chile	3065
Bernardo O'Higgins	National Park	II	Chile	56
