ABSTRACT

The delta-lognormal distribution is a combination of binomial and lognormal distributions, and so rainfall series that include zero and positive values conform to this distribution. The coefficient of variation is a good tool for measuring the dispersion of rainfall. Statistical estimation can be used not only to illustrate the dispersion of rainfall but also to describe the differences between rainfall dispersions from several areas simultaneously. Therefore, the purpose of this study is to construct simultaneous confidence intervals for all pairwise differences between the coefficients of variation of delta-lognormal distributions using three methods: fiducial generalized confidence interval, Bayesian, and the method of variance estimates recovery. Their performances were gauged by measuring their coverage probabilities together with their expected lengths via Monte Carlo simulation. The results indicate that the Bayesian credible interval using the Jeffreys' rule prior outperformed the others in virtually all cases. Rainfall series from five regions in Thailand were used to demonstrate the efficacies of the proposed methods.

INTRODUCTION

Thailand is located in Southeast Asia and is classed as a tropical area. It is influenced by both the southwest and northeast monsoons. The southwest monsoon crosses Thailand between mid-May to mid-October (the rainy season) and brings moist air from the Indian Ocean that causes clouds and heavy rain. The northeast monsoon crosses Thailand from mid-October to mid-February (the winter season) causing cold and dry weather. Moreover, the South receives additional heavy rainfall due to moisture coming in from the Gulf of Thailand. The season changes from mid-February to mid-May (the summer season) due to uncertainty in the weather and is influenced by tropical cyclones in the South China Sea, and thus, the weather is generally hot and dry but often with heavy rain and thunderstorms (Thai Meteorological Department, 2015). Thailand often endures flooding due to thunderstorms, which can take lives and damage property, especially on farms due to Thailand being an agricultural country. Thailand is divided into five regions according to its climate pattern and meteorological conditions (Table 1) (Thai Meteorological Department, 2015). Therefore, it is important to investigate rainfall dispersion in each area to gain preliminary information for formulating policies to mitigate such incidents.

There have been numerous studies on rainfall series that have used the delta-lognormal distribution. Fukuchi (1988) derived the distribution of correlation coefficients of rainfall rates from two areas as bivariate lognormal (delta-lognormal). Kedem (1990) showed that the average rain rate over an area follows a delta-lognormal distribution. Shimizu (1993) and Kong et al. (2012) presented the maximum likelihood estimation of the parameters of rainfall series containing zeros that followed a bivariate lognormal distribution. Moreover, examples of rainfall series that conform to a delta-lognormal distribution can be founded in various studies by Maneerat et al. (2019a,b, 2020a,b), Yosboonruang et al. (2019b, 2020), and Yosboonruang and Niwitpong (2020). In addition, a delta-lognormal distribution has been

applied in other fields, such as Ingram Jr. et al. (2010), Owen and DeRouen (1980), Fletcher (2008), Wu and Hsieh (2014), and Zhou and Tu (2000). Constructing the confidence intervals for several parameters of a delta-lognormal distribution used in statistical inference has been of interest to many researchers. Confidence intervals for the delta-lognormal mean were proposed by Owen and DeRouen (1980), Kvanli et al. (1998), Zhou and Tu (2000), Tian (2005), Chen and Zhou (2006), Tian and Wu (2006), Fletcher (2008), Li et al. (2013), Wu and Hsieh (2014), Hasan and Krishnamoorthy (2018), and Maneerat et al. (2018, 2019a,b). Furthermore, the confidence intervals for variance and the coefficient of variation (CV) of a delta-lognormal distribution were presented by Buntao and Niwitpong (2012, 2013), Yosboonruang et al. (2018, 2019a,b, 2020), Yosboonruang and Niwitpong (2020), and Maneerat et al. (2020a,b).

For statistical inference, the CV, the ratio of the standard deviation to the mean, is a good tool for investigating rainfall dispersion. The advantage of using the CV is that it is unitless and thus, is useful for measuring dispersion in data series with different units or drastically different means. Focusing on inferential statistics, the confidence intervals and functions of the CV for several distributions have been presented. Wong and Wu (2002) suggested a small-sample asymptotic method for constructing the confidence intervals for the CV of normal and non-normal distributions when the sample size is very small. Mahmoudvand and Hassani (2009) proposed two new methods for constructing the confidence intervals for the CV of a normal distribution and compared them with Miller's, Makay's, Vangel's, and Sharma-Krishna's methods; they found that their proposed methods are more appropriate than the others. Buntao and Niwitpong (2012) proposed the generalized pivotal approach (GPA) and a closed-form method for variance estimation for the difference between the CVs of lognormal and delta-lognormal distributions; their results show that the GPA is the most suitable. After that, they constructed the confidence intervals for the ratio of the CVs of delta-lognormal distributions using GPA and the method of variance estimates recovery (MOVER) (Buntao and Niwitpong, 2013); their results were similar to the confidence intervals for the difference between the CVs. Wongkhao et al. (2015) presented the generalized confidence interval (GCI) and MOVER to construct the confidence intervals for the ratio of CVs of normal distributions and then compared their methods with the Verrill and Johnson and bootstrapping methods; they found that GCI and MOVER performed better than the others. Sangnawakij and Niwitpong (2017a) proposed MOVER, GCI, and the asymptotic confidence interval (ACI) for constructing the confidence interval for the CV and difference between the CVs of two-parameter exponential distributions; their results show that GCI was appropriate for a single CV and ACI worked well for the difference between the CVs. In addition, confidence intervals were extended by Sangnawakij and Niwitpong (2017b) based on the score and Wald intervals for the difference between and ratio of CVs of two gamma distributions; their proposed methods performed well in a comparative study. Recently, Yosboonruang et al. (2018) proposed GCI and a modified Fletcher method to construct the confidence intervals for the CV of a delta-lognormal distribution and found that GCI was the best. Afterward, they introduced the fiducial GCI (FGCI) and MOVER to construct the confidence intervals for the CV of a delta-lognormal distribution (Yosboonruang et al., 2019a). Moreover, they compared the confidence intervals based on FGCI and a Bayesian method

for the CV of a delta-lognormal distribution (Yosboonruang et al., 2019b); their results indicate that the Bayesian method outperformed FGCI. Yosboonruang and Niwitpong (2020) constructed confidence intervals using GCI and MOVER based on variance stabilizing transformation, the Wilson score, and Jeffreys' method for the ratio of the CVs of delta-lognormal distributions; their results show that GCI was the most suitable. Yosboonruang et al. (2020) presented FGCI and a Bayesian method to construct the confidence interval for the difference of CVs of delta-lognormal distributions; they concluded that the Bayesian method was the most appropriate.

Since dispersion in the precipitation series for different areas can be the same or different, simultaneous estimation of this for multiple areas has been investigated using various distributions and parameters. Mandel and Betensky (2008) introduced an algorithm for simultaneous confidence interval (SCI) construction and then compared bootstrapped and normal-based SCIs in which the limits of the bootstrap intervals were smaller than the normal-based intervals. Donner and Zou (2011) used a two-step MOVER approach for constructing SCIs for multiple contrasts of binomial proportions; their proposed method was reasonable for small-to-moderate sample sizes. Abdel-Karim (2015) considered three methods: FGCI-MOVER, MOVER-MOVER, and simultaneous FGCI to construct SCIs for the ratio of means of lognormal distributions; they reported that the MOVER-MOVER method outperformed the others. Li et al. (2015) suggested parametric bootstrapping to construct SCIs for all pairwise differences between the means of two-parameter exponential distributions. Thangjai et al. (2019) presented three methods: MOVER, a computational approach, and FGCI to construct SCIs for all of the differences between the CVs of lognormal distributions; their results show that MOVER was the best and the computational approach performed similarly to MOVER when the sample size was large. In addition, Thangjai and Niwitpong (2020) used parametric bootstrapping, GCI, and MOVER for SCI construction for all of the differences between CVs in two-parameter exponential distributions; their results indicate that GCI was the most appropriate in most cases, while MOVER was the best for large sample sizes.

As mentioned above, rainfall series data follow a delta-lognormal distribution. Since our focus is on comparing the dispersion of rainfall from five regions in Thailand, the pairwise differences between the CVs of their rainfall data distributions are an interesting topic to study. Although there have been numerous methods published for constructing SCIs for the differences between the parameters of several types of distributions, constructing SCIs for all of the pairwise differences between the CVs of delta-lognormal distributions has not yet been reported. GCI is a general method that is often used to construct confidence intervals, but FGCI is stronger than GCI since it provides asymptotically correct frequentist coverage (Hannig et al., 2005). Moreover, previous researchers have reported that MOVER is an appropriate method for constructing the SCIs for various parameters of several types of distributions. Therefore, one of ours aims was to construct SCIs for this scenario based on FGCI and compare them with ones based on MOVER and Bayesian methodology. The coverage probability, the probability that the confidence interval of the estimate covers the value of the parameter, together with the expected length were used to estimate the performance of the confidence intervals.

METHODS

Let $X_i = (X_{i1}, X_{i2}, \dots, X_{im_i})$, $i = 1, 2, \dots, k$ be a random sample from k independent delta-lognormal distributions, denoted by $X_{ij} \sim \Delta(\mu_i, \sigma_i^2, \delta_{i(0)})$, where $\delta_{i(0)} = P(X_{ij} = 0)$. Since this distribution contains zero and positive values, then the zero values follow a binomial distribution and the positive values a lognormal distribution denoted by $X_{ij} = 0 \sim \text{Bin}(n_i, \delta_{i(0)})$ and $Y_{ij} = \ln(X_{ij}) \sim N(\mu_i, \sigma_i^2)$, respectively. Moreover, let $n_{i(0)}$ and $n_{i(1)}$ be the numbers of zero and positive values, respectively, where $n_i = n_{i(0)} + n_{i(1)}$. The distribution function of a delta-lognormal distribution is given by

$$f(x_{ij}; \mu_i, \sigma_i^2, \delta_{i(0)}) = \begin{cases} \delta_{i(0)} & ; x_{ij} = 0 \\ \delta_{i(1)} \frac{1}{\sqrt{2\pi}\sigma_i} \left(\frac{1}{x_{ij}}\right) \exp\left\{-\frac{[\ln(x_{ij}) - \mu_i]^2}{2\sigma_i^2}\right\} & ; x_{ij} > 0 \end{cases} \quad (1)$$

where $\delta_{i(1)} = 1 - \delta_{i(0)}$. Following Aitchison (1955), the respective population mean and variance of X_i are

$$E(X_i) = \mu_{X_i} = \delta_{i(1)} \exp\left(\mu_i + \frac{\sigma_i^2}{2}\right) \quad (2)$$

and

$$\text{Var}(X_i) = \sigma_{X_i}^2 = \delta_{i(1)} \exp(2\mu_i + \sigma_i^2) [\exp(\sigma_i^2) - \delta_{i(1)}]. \quad (3)$$

Following this, the CV of X_i can be expressed as

$$\text{CV}(X_i) = v_i = \sqrt{\frac{\exp(\sigma_i^2) - \delta_{i(1)}}{\delta_{i(1)}}}. \quad (4)$$

Since we are interested in constructing the SCIs for all pairwise differences between the CVs, then

$$v_{il} = v_i - v_l = \sqrt{\frac{\exp(\sigma_i^2) - \delta_{i(1)}}{\delta_{i(1)}}} - \sqrt{\frac{\exp(\sigma_l^2) - \delta_{l(1)}}{\delta_{l(1)}}}, \quad (5)$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$. The maximum likelihood estimators of $\delta_{i(1)}$ and μ_i are $\hat{\delta}_{i(1)} = n_{i(1)}/n_i$ and $\hat{\mu}_i = \sum_{j=1}^{n_{i(1)}} \ln(x_{ij})/n_{i(1)}$, respectively. Furthermore, the unbiased estimator for σ_i^2 is $\hat{\sigma}_i^2 = \sum_{j=1}^{n_{i(1)}} [\ln(x_{ij}) - \hat{\mu}_i]^2 / (n_{i(1)} - 1)$.

Assume that $\hat{\delta}_{i(1)}$ and $\hat{\sigma}_i^2$ are independent, then the maximum likelihood estimator of v_i can be defined as

$$\hat{v}_i = \sqrt{\frac{\exp(\hat{\sigma}_i^2) - \hat{\delta}_{i(1)}}{\hat{\delta}_{i(1)}}}. \quad (6)$$

Similarly,

$$\hat{v}_{il} = \hat{v}_i - \hat{v}_l = \sqrt{\frac{\exp(\hat{\sigma}_i^2) - \hat{\delta}_{i(1)}}{\hat{\delta}_{i(1)}}} - \sqrt{\frac{\exp(\hat{\sigma}_l^2) - \hat{\delta}_{l(1)}}{\hat{\delta}_{l(1)}}}, \quad (7)$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$.

According to Yosboonruang et al. (2020), the estimated variance of $\hat{v}_i - \hat{v}_l$ can be expressed as

$$\begin{aligned} \widehat{\text{Var}}(\hat{v}_i - \hat{v}_l) = & \frac{\left\{ \left[\ln(\hat{\delta}_{i(1)}) + \ln\left(\frac{\exp(\hat{\sigma}_i^2) - \hat{\delta}_{i(1)}}{\hat{\delta}_{i(1)}} + 1\right) \right] \left[\frac{\exp(\hat{\sigma}_i^2) - \hat{\delta}_{i(1)}}{\hat{\delta}_{i(1)}} + 1 \right] \right\}^2}{2n_i \left[\frac{\exp(\hat{\sigma}_i^2) - \hat{\delta}_{i(1)}}{\hat{\delta}_{i(1)}} \right]} \\ & + \frac{\left\{ \left[\ln(\hat{\delta}_{l(1)}) + \ln\left(\frac{\exp(\hat{\sigma}_l^2) - \hat{\delta}_{l(1)}}{\hat{\delta}_{l(1)}} + 1\right) \right] \left[\frac{\exp(\hat{\sigma}_l^2) - \hat{\delta}_{l(1)}}{\hat{\delta}_{l(1)}} + 1 \right] \right\}^2}{2n_l \left[\frac{\exp(\hat{\sigma}_l^2) - \hat{\delta}_{l(1)}}{\hat{\delta}_{l(1)}} \right]}, \end{aligned} \quad (8)$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$.

The simultaneous FGCI

To construct the simultaneous FGCI, a fiducial generalized pivotal quantity (FGPQ), which is a subclass of the generalized pivotal quantity (GPQ) (Hannig et al., 2006), is presented as follows.

Definition 1. Let $X_i = (X_{i1}, X_{i2}, \dots, X_{in_i})$, $i = 1, 2, \dots, k$ be a random sample from k independent delta-lognormal distributions with parameters of interest $(\sigma_i^2, \delta_{i(1)})$ and nuisance parameter μ_i . Let $x_i = (x_{i1}, x_{i2}, \dots, x_{in_i})$, $i = 1, 2, \dots, k$, be an observed value of X_i . GPQ $R(X_i; x_i, \mu_i, \sigma_i^2, \delta_{i(1)})$ is called an FGPQ if it corresponds with the following two conditions (Weerahandi, 1993; Hannig et al., 2006):

1. For a given x_i , the conditional distribution of $R(X_i; x_i, \mu_i, \sigma_i^2, \delta_{i(1)})$ is free of μ_i .
2. The observed value of $R(X_i; x_i, \mu_i, \sigma_i^2, \delta_{i(1)})$ at $X_i = x_i$, $r(x_i; x_i, \mu_i, \sigma_i^2, \delta_{i(1)})$ is the parameter of interest.

The FGPs for σ_i^2 and $\delta_{i(1)}$ can be constructed by applying Definition 1. According to Hannig et al. (2006) and Li et al. (2013), the respective FGPs for $\delta_{i(1)}$ and σ_i^2 are

$$R_{\delta_{i(1)}} \sim \frac{1}{2} \text{Beta}(n_{i(1)}, n_{i(0)} + 1) + \frac{1}{2} \text{Beta}(n_{i(1)} + 1, n_{i(0)}) \quad (9)$$

and

$$R_{\sigma_i^2} = \frac{(n_{i(1)} - 1) \hat{\sigma}_i^2}{U_i}, \quad (10)$$

where $U_i \sim \chi_{n_{i(1)}-1}^2$. Following this, the FGP for v_i is simply

$$R_{v_i} = \sqrt{\frac{\exp(R_{\sigma_i^2}) - R_{\delta_{i(1)}}}{R_{\delta_{i(1)}}}}. \quad (11)$$

Hence, the FGP for the differences between two independent CVs can be expressed as

$$R_{v_{il}} = R_{v_i} - R_{v_l} = \sqrt{\frac{\exp(R_{\sigma_i^2}) - R_{\delta_{i(1)}}}{R_{\delta_{i(1)}}}} - \sqrt{\frac{\exp(R_{\sigma_l^2}) - R_{\delta_{l(1)}}}{R_{\delta_{l(1)}}}}, \quad (12)$$

136 where $i, l = 1, 2, \dots, k$ and $i \neq l$.

137 Therefore, the $100(1 - \alpha)\%$ two-sided SCI for $v_i - v_l$ based on the FGCI method can be written as
138 $L_{il} \leq v_{il} \leq U_{il}$, where L_{il} and U_{il} are the $\alpha/2$ -th and $(1 - \alpha/2)$ -th quantiles of $R_{v_{il}}$, respectively.

Theorem 1. Let $X_i = (X_{i1}, X_{i2}, \dots, X_{in_i})$, $i = 1, 2, \dots, k$ be a random sample from k independent delta-lognormal distributions with mean μ_i , variance σ_i^2 , and probability of zero values $\delta_{i(0)}$. Let $v_i = \sqrt{[\exp(\sigma_i^2) - \delta_{i(1)}] / \delta_{i(1)}}$ and $v_l = \sqrt{[\exp(\sigma_l^2) - \delta_{l(1)}] / \delta_{l(1)}}$ for $i, l = 1, 2, \dots, k$ and $i \neq l$ be the CV of X_i and X_l , respectively. Furthermore, let \hat{v}_i and \hat{v}_l be the estimators of v_i and v_l , respectively. The estimator for the variance of the difference between v_i and v_l is $\widehat{\text{Var}}(\hat{v}_i - \hat{v}_l)$. Let n_i be the sample size of the i^{th} random sample and $n = n_1 + n_2 + \dots + n_k$. Assume that $n_i/n \rightarrow r_i$ as $n \rightarrow \infty$ where $0 < r_i < 1$. Therefore,

$$P[R_{v_{il}}(\alpha/2) \leq R_{v_{il}} \leq R_{v_{il}}(1 - \alpha/2), \forall i \neq l] \rightarrow 1 - \alpha. \quad (13)$$

Proof. Since

$$P[R_{v_{il}}(\alpha/2) \leq R_{v_{il}} \leq R_{v_{il}}(1 - \alpha/2), \forall i \neq l] = P[L_{il} \leq v_i - v_l \leq U_{il}, \forall i \neq l],$$

139 where $[L_{il}, U_{il}] = \hat{v}_i - \hat{v}_l \pm d_{1-\alpha} \sqrt{\widehat{\text{Var}}(\hat{v}_i - \hat{v}_l)}$ and $d_{1-\alpha}$ denotes the $(1 - \alpha)$ -th quantile of $R_{v_{il}}$. Thus,

$$\begin{aligned} P[L_{il} \leq v_i - v_l \leq U_{il}, \forall i \neq l] &= P\left[\max_{i \neq l} \left| \frac{\hat{v}_i - \hat{v}_l - (v_i - v_l)}{\sqrt{\widehat{\text{Var}}(\hat{v}_i - \hat{v}_l)}} \right| \leq d_{1-\alpha}\right] \\ &= P[D_n \leq d_{1-\alpha}]. \end{aligned}$$

Accordingly,

$$P[L_{il} \leq v_i - v_l \leq U_{il}, \forall i \neq l] \rightarrow 1 - \alpha.$$

This implies that

$$P[R_{v_{il}}(\alpha/2) \leq R_{v_{il}} \leq R_{v_{il}}(1 - \alpha/2), \forall i \neq l] \rightarrow 1 - \alpha.$$

140

□

141 **The Bayesian method**

According to the distributions of X_i for $i = 1, 2, \dots, k$ with the unknown parameters μ_i , σ_i^2 , and $\delta_{i(0)}$, where $\delta_{i(0)} = 1 - \delta_{i(1)}$, the joint likelihood function of k independent delta-lognormal distributions is

$$L(\mu_i, \sigma_i^2, \delta_{i(1)} | x_{ij}) \propto \prod_{i=1}^k (1 - \delta_{i(1)})^{n_{i(0)}} \delta_{i(1)}^{n_{i(1)}} (\sigma_i^2)^{-\frac{n_{i(1)}}{2}} \exp \left\{ -\frac{1}{2\sigma_i^2} \sum_{j=1}^{n_{i(1)}} [\ln(x_{ij}) - \mu_i]^2 \right\}. \quad (14)$$

By applying the second-order partial derivative of the log-likelihood function with respect to the unknown parameters, the Fisher information matrix of the unknown parameters can be written as

$$I(\mu_i, \sigma_i^2, \delta_{i(1)}) = \text{diag} \left[\frac{n_1}{(1-\delta_{i(1)})\delta_{i(1)}}, \frac{n_1\delta_{i(1)}}{\sigma_i^2}, \frac{n_1\delta_{i(1)}}{2(\sigma_i^2)^2}, \dots, \dots, \dots, \frac{n_k}{(1-\delta_{k(1)})\delta_{k(1)}}, \frac{n_k\delta_{k(1)}}{\sigma_k^2}, \frac{n_k\delta_{k(1)}}{2(\sigma_k^2)^2} \right]. \quad (15)$$

142 In this paper, we constructed both of equal-tailed SCIs based on simulation data and simultaneous
 143 credible intervals based on information from a simulation study of their prior distributions using two forms
 144 of Bayesian prior; the suitability of the Jeffreys' rule and uniform priors was determined by considering the
 145 values of a random variable of their posterior distributions that correspond to those for a delta-lognormal
 146 distribution. See also, Yosboonruang et al. (2019b) and Yosboonruang et al. (2020).

147 **The Jeffreys' rule prior**

148 The Jeffreys' rule prior is obtained from the square root of the determinant of the Fisher information
 149 matrix (Jeffreys, 1946). It is well known that a delta-lognormal distribution comprises lognormal and
 150 binomial distributions. From the CVs in Eq. (4), the parameters of interest are σ_i^2 and $\delta_{i(1)}$, and the
 151 Jeffreys' rule priors for these parameters are $p(\sigma_i^2) \propto \sigma_i^{-3}$ and $p(\delta_{i(1)}) \propto (1 - \delta_{i(1)})^{-\frac{1}{2}} \delta_{i(1)}^{\frac{1}{2}}$, respectively.
 152 Assuming that σ_i^2 and $\delta_{i(1)}$ are independent, the prior distribution for a delta-lognormal distribution can
 153 be defined as $p(\sigma_i^2, \delta_{i(1)}) \propto \sigma_i^{-3} (1 - \delta_{i(1)})^{-\frac{1}{2}} \delta_{i(1)}^{\frac{1}{2}}$. By combining the likelihood function and the prior
 154 distribution of a delta-lognormal distribution, the joint posterior density function can be written as

$$p(\sigma_i^2, \delta_{i(1)} | x_{ij}) = \prod_{i=1}^k \frac{1}{\text{Beta}(n_{i(0)} + \frac{1}{2}, n_{i(1)} + \frac{3}{2})} (1 - \delta_{i(1)})^{(n_{i(0)} + \frac{1}{2}) - 1} \delta_{i(1)}^{(n_{i(1)} + \frac{3}{2}) - 1} \\ \times \frac{1}{\sqrt{2\pi} \frac{\sigma_i}{\sqrt{n_{i(1)}}}} \exp \left[-\frac{1}{2 \frac{\sigma_i^2}{n_{i(1)}}} (\mu_i - \hat{\mu}_i)^2 \right] \frac{\left(\frac{n_{i(1)} \hat{\sigma}_i^2}{2} \right)^{\frac{n_{i(1)}}{2}}}{\Gamma\left(\frac{n_{i(1)}}{2}\right)} (\sigma_i^2)^{-\frac{n_{i(1)}}{2} - 1} \exp \left(-\frac{n_{i(1)} \hat{\sigma}_i^2}{2 \sigma_i^2} \right), \quad (16)$$

155 where $\hat{\mu}_i = \sum_{j=1}^{n_{i(1)}} \ln(x_{ij}) / n_{i(1)}$, and $\hat{\sigma}_i^2 = \sum_{j=1}^{n_{i(1)}} [\ln(x_{ij}) - \hat{\mu}_i]^2 / (n_{i(1)} - 1)$.

By integrating Eq. (16), the respective posterior distributions of σ_i^2 and $\delta_{i(1)}$ are derived as

$$p(\sigma_i^2 | x_{ij}) \propto \prod_{i=1}^k \frac{\left(\frac{n_{i(1)} \hat{\sigma}_i^2}{2} \right)^{\frac{n_{i(1)}}{2}}}{\Gamma\left(\frac{n_{i(1)}}{2}\right)} (\sigma_i^2)^{-\frac{n_{i(1)}}{2} - 1} \exp \left(-\frac{n_{i(1)} \hat{\sigma}_i^2}{2 \sigma_i^2} \right), \quad (17)$$

and

$$p(\delta_{i(1)} | x_{ij}) \propto \prod_{i=1}^k \frac{1}{\text{Beta}(n_{i(0)} + \frac{1}{2}, n_{i(1)} + \frac{3}{2})} (1 - \delta_{i(1)})^{(n_{i(0)} + \frac{1}{2}) - 1} \delta_{i(1)}^{(n_{i(1)} + \frac{3}{2}) - 1}. \quad (18)$$

156 It should be noted that $p(\sigma_i^2 | x_{ij})$ follows an inverse gamma distribution and $p(\delta_{i(1)} | x_{ij})$ follows a beta
 157 distribution, denoted by $\sigma_i^2 | x_{ij} \sim \text{Inv} - \text{Gamma}(n_{i(1)}/2, n_{i(1)} \hat{\sigma}_i^2/2)$ and $\delta_{i(1)} | x_{ij} \sim \text{Beta}(n_{i(0)} + 1/2,$
 158 $n_{i(1)} + 3/2)$, respectively. Consequently, $\sigma_i^2 | x_{ij}$ and $\delta_{i(1)} | x_{ij}$ can be substituted into Eq. (5) to construct
 159 the equal-tailed SCI and the simultaneous credible interval, respectively.

The uniform prior

Since the uniform prior has a constant function for the prior probability (Stone, 2013), then the uniform priors of σ_i^2 and $\delta_{i(1)}$ are 1, denoted by $p(\sigma_i^2) \propto 1$ and $p(\delta_{i(1)}) \propto 1$, respectively. Afterward, the uniform prior for a delta-lognormal distribution becomes $p(\sigma_i^2, \delta_{i(1)}) \propto 1$. Similar to Eq. (16), the joint posterior density function is obtained by combining $p(\sigma_i^2, \delta_{i(1)})$ with the likelihood function from Eq. (14). Subsequently, we obtain the posterior of σ_i^2 and $\delta_{i(1)}$ by integrating the joint posterior density function with respect to the others. Thus, the posterior distribution is $\sigma_i^2 | x_{ij} \sim \text{Inv-Gamma}[(n_{i(1)} - 2)/2, (n_{i(1)} - 2)\hat{\sigma}_i^2/2]$ for σ_i^2 and $\delta_{i(1)} | x_{ij} \sim \text{Beta}(n_{i(0)} + 1, n_{i(1)} + 1)$ for $\delta_{i(1)}$.

Therefore, the $100(1 - \alpha)\%$ equal-tailed SCI and simultaneous credible interval for v_{il} based on the Bayesian method are $L_{il} \leq v_{il} \leq U_{il}$, where L_{il} and U_{il} are the lower and upper bounds of the intervals, respectively.

Theorem 2. Let $X_i = (X_{i1}, X_{i2}, \dots, X_{in_i}) \sim \Delta(\mu_i, \sigma_i^2, \delta_{i(1)})$, where $i = 1, 2, \dots, k$ and $\delta_{i(0)} = 1 - \delta_{i(1)}$, with sample sizes n_1, n_2, \dots, n_k and $n = n_1 + n_2 + \dots + n_k$. Let $r_i = n_i/n \rightarrow \infty$, where $0 < r_i < 1$. For $i, l = 1, 2, \dots, k$ and $i \neq l$, let $v_i = \sqrt{[\exp(\sigma_i^2) - \delta_{i(1)}]/\delta_{i(1)}}$ and $v_l = \sqrt{[\exp(\sigma_l^2) - \delta_{l(1)}]/\delta_{l(1)}}$ be the CVs of X_i and X_l , respectively. Let \hat{v}_i and \hat{v}_l be the estimators of v_i and v_l , respectively. An estimator for the variance of the difference between v_i and v_l is $\text{Var}(\hat{v}_i - \hat{v}_l)$. Let $p(\sigma_i^2, \delta_{i(1)})$ and $p(\sigma_i^2, \delta_{i(1)} | x_{ij})$ be the prior distribution and the joint posterior density function for delta-lognormal distribution, respectively. Therefore,

$$P[L_{il} \leq v_{il} \leq U_{il}, \forall i \neq l] \rightarrow 1 - \alpha. \quad (19)$$

Proof. The proof is similar to Theorem 1. □

Algorithm 1: For the FGCI and Bayesian methods

Step 1. Generate random samples X_i , $i = 1, 2, \dots, k$, with sample sizes n_1, n_2, \dots, n_k and calculate $\hat{\delta}_{i(1)}$ and $\hat{\sigma}_i^2$.

Step 2. Generate $U_i \sim \chi_{n_{i(1)}-1}^2$, $\text{Beta}(n_{i(1)}, n_{i(1)} + 1)$, $\text{Beta}(n_{i(1)} + 1, n_{i(1)})$, $\text{Beta}(n_{i(0)} + 1/2, n_{i(1)} + 3/2)$, $\text{Beta}(n_{i(0)} + 1, n_{i(1)} + 1)$, $\text{Inv-Gamma}(n_{i(1)}/2, n_{i(1)}\hat{\sigma}_i^2/2)$, and $\text{Inv-Gamma}[(n_{i(1)} - 2)/2, (n_{i(1)} - 2)\hat{\sigma}_i^2/2]$.

Step 3. Calculate $R_{\delta_{i(1)}}$, $R_{\sigma_i^2}$, R_{v_i} , R_{v_l} , v_i , and v_l .

Step 4. Repeat Steps 2–3 5,000 times.

Step 5. Compute the 95% SCIs for v_{il} .

Step 6. Repeat Steps 1–5 15,000 times.

MOVER

The concept of MOVER proposed by Donner and Zou (2012) can be applied to construct the $100(1 - \alpha)\%$ two-sided confidence interval of $v_i - v_l$ for $i, l = 1, 2, \dots, k$ and $i \neq l$, for which $L_{il} \leq v_{il} \leq U_{il}$ where L_{il} and U_{il} denote the lower and upper limits of the confidence interval, respectively, expressed as

$$L_{il} = \hat{v}_i - \hat{v}_l - \sqrt{(\hat{v}_i - l_i)^2 + (u_l - \hat{v}_l)^2} \quad (20)$$

and

$$U_{il} = \hat{v}_i - \hat{v}_l + \sqrt{(u_i - \hat{v}_i)^2 + (\hat{v}_l - l_l)^2}, \quad (21)$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$. From Eq. (4), the parameters of interest are $\delta_{i(1)}$ and σ_i^2 , and so the confidence intervals for these parameters can be constructed.

Since the unbiased estimator of σ_i^2 is given by $\hat{\sigma}_i^2 = \sum_{j=1}^{n_{i(1)}} [\ln(x_{ij}) - \hat{\mu}_i]^2 / (n_{i(1)} - 1)$, for $i = 1, 2, \dots, k$ and where $(n_{i(1)} - 1) \hat{\sigma}_i^2 / \sigma_i^2 \sim \chi_{n_{i(1)} - 1}^2$. Consequently, the respective lower and upper bounds for σ_i^2 are defined as

$$l_{\sigma_i^2} = \frac{(n_{i(1)} - 1) \hat{\sigma}_i^2}{\chi_{1-\frac{\alpha}{2}, n_{i(1)} - 1}^2} \quad (22)$$

and

$$u_{\sigma_i^2} = \frac{(n_{i(1)} - 1) \hat{\sigma}_i^2}{\chi_{\frac{\alpha}{2}, n_{i(1)} - 1}^2}. \quad (23)$$

The score method proposed by Wilson (1927) is used to construct the confidence limits for $\delta_{i(1)}$. According to Brown et al. (2001) and Donner and Zou (2011), the respective lower and upper limits of $\delta_{i(1)}$ are given by

$$l_{\delta_{i(1)}} = \frac{n_{i(1)} + \frac{Z_{i(\alpha/2)}^2}{2}}{n_i + Z_{i(\alpha/2)}^2} - Z_{i(\alpha/2)} \frac{\sqrt{\frac{n_{i(0)}n_{i(1)}}{n_i} + \frac{Z_{i(\alpha/2)}^2}{4}}}{n_i + Z_{i(\alpha/2)}^2} \quad (24)$$

and

$$u_{\delta_{i(1)}} = \frac{n_{i(1)} + \frac{Z_{i(\alpha/2)}^2}{2}}{n_i + Z_{i(\alpha/2)}^2} + Z_{i(\alpha/2)} \frac{\sqrt{\frac{n_{i(0)}n_{i(1)}}{n_i} + \frac{Z_{i(\alpha/2)}^2}{4}}}{n_i + Z_{i(\alpha/2)}^2}, \quad (25)$$

where Z_i , $i = 1, 2, \dots, k$ follow a standard normal distribution. This approach is similar to constructing the confidence limits for σ_i^2 and $\delta_{i(1)}$.

Therefore, the $100(1 - \alpha)\%$ two-sided SCIs for $v_i - v_l$ based on the MOVER method are

$$SCI_{il} = [L_{il}, U_{il}], \quad (26)$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$.

Theorem 3. Let $X_i = (X_{i1}, X_{i2}, \dots, X_{in_i})$, $i = 1, 2, \dots, k$, be random samples from k independent delta-lognormal distributions with mean μ_i , variance σ_i^2 , and probability of zero values $\delta_{i(0)}$. Furthermore, let the sample size of the i^{th} random sample be n_i , where $n = n_1 + n_2 + \dots + n_k$ and $r_i = n_i/n$ as $n \rightarrow \infty$, for which $0 < r_i < 1$. Let $v_i = \sqrt{[\exp(\sigma_i^2) - \delta_{i(1)}] / \delta_{i(1)}}$ and $v_l = \sqrt{[\exp(\sigma_l^2) - \delta_{l(1)}] / \delta_{l(1)}}$, for $i, l = 1, 2, \dots, k$ and $i \neq l$, be the CVs of X_i and X_l , respectively. In addition, let \hat{v}_i and \hat{v}_l be the estimators of v_i and v_l , respectively. Let $L_{il} = \hat{v}_i - \hat{v}_l - \sqrt{(\hat{v}_i - l_i)^2 + (u_l - \hat{v}_l)^2}$ and $U_{il} = \hat{v}_i - \hat{v}_l + \sqrt{(u_i - \hat{v}_i)^2 + (\hat{v}_l - l_l)^2}$, where $i, l = 1, 2, \dots, k$ and $i \neq l$, be the respective lower and upper limits of the confidence interval for $v_{il} = v_i - v_l$. Therefore,

$$P(L_{il} \leq v_{il} \leq U_{il}, \forall i \neq l) \rightarrow 1 - \alpha. \quad (27)$$

Proof. Suppose that the respective lower and upper limits of the confidence interval for $v_{il} = v_i - v_l$ are

$$L_{il} = \hat{v}_i - \hat{v}_l - \sqrt{(\hat{v}_i - l_i)^2 + (u_l - \hat{v}_l)^2} = \hat{v}_{il} - \sqrt{(\hat{v}_i - l_i)^2 + (u_l - \hat{v}_l)^2}$$

and

$$U_{il} = \hat{v}_i - \hat{v}_l + \sqrt{(u_i - \hat{v}_i)^2 + (\hat{v}_l - l_l)^2} = \hat{v}_{il} + \sqrt{(u_i - \hat{v}_i)^2 + (\hat{v}_l - l_l)^2},$$

where $i, l = 1, 2, \dots, k$ and $i \neq l$. Thus, the respective estimators of variance for \hat{v}_i and \hat{v}_l at $v_i = l_i$ and $v_l = l_l$ are

$$\widehat{Var}(\hat{v}_i) = \frac{(\hat{v}_i - l_i)^2}{z_{\alpha/2}^2}$$

and

$$\widehat{Var}(\hat{v}_l) = \frac{(\hat{v}_l - l_l)^2}{z_{\alpha/2}^2},$$

where $z_{\alpha/2}$ is the $\alpha/2$ -th quantile of the standard normal distribution. Similarly, the respective estimators of variance for \hat{v}_i and \hat{v}_l at $v_i = u_i$ and $v_l = u_l$ are

$$\widehat{Var}(\hat{v}_i) = \frac{(u_i - \hat{v}_i)^2}{z_{\alpha/2}^2}$$

and

$$\widehat{Var}(\hat{v}_l) = \frac{(u_l - \hat{v}_l)^2}{z_{\alpha/2}^2}.$$

Hence, the respective lower and upper limits can be expressed as

$$\begin{aligned} L_{il} &= \hat{v}_{il} - z_{\alpha/2} \sqrt{\frac{(\hat{v}_i - l_i)^2}{z_{\alpha/2}^2} + \frac{(u_l - \hat{v}_l)^2}{z_{\alpha/2}^2}} \\ &= \hat{v}_{il} - z_{\alpha/2} \sqrt{\widehat{Var}(\hat{v}_i) + \widehat{Var}(\hat{v}_l)} \end{aligned}$$

and

$$\begin{aligned} U_{il} &= \hat{v}_{il} + z_{\alpha/2} \sqrt{\frac{(u_i - \hat{v}_i)^2}{z_{\alpha/2}^2} + \frac{(\hat{v}_l - l_l)^2}{z_{\alpha/2}^2}} \\ &= \hat{v}_{il} + z_{\alpha/2} \sqrt{\widehat{Var}(\hat{v}_i) + \widehat{Var}(\hat{v}_l)}. \end{aligned}$$

Therefore,

$$\begin{aligned} P(L_{il} \leq v_{il} \leq U_{il}) &= P\left[v_{il} \in \left(\hat{v}_{il} \pm z_{\alpha/2} \sqrt{\widehat{Var}(\hat{v}_i) + \widehat{Var}(\hat{v}_l)}\right), \forall i \neq l\right] \\ &= P\left[\max_{i \neq l} \left| \frac{\hat{v}_{il} - v_{il}}{\sqrt{\widehat{Var}(\hat{v}_i) + \widehat{Var}(\hat{v}_l)}} \right| \leq z_{\alpha/2}\right] \\ &= P[D'_n \leq z_{\alpha/2}]. \end{aligned}$$

Suppose that $n_i/n \rightarrow r_i \in (0, 1)$ as $n \rightarrow \infty$, $i = 1, 2, \dots, k$ where $n = n_1 + n_2 + \dots + n_k$. From the central limit theorem, $n(\hat{v}_i - v_i) \xrightarrow{d} Z_i$, $i = 1, 2, \dots, k$, where $Z_i \stackrel{iid}{\sim} N(0, \sigma_i^2/r_i)$, while from Slutsky's theorem, $D'_n \rightarrow D'$, where $D' = \max_{i \neq l} \left| (Z_i - Z_l) / \sqrt{\sigma_i^2/r_i + \sigma_l^2/r_l} \right|$.

Following Skorokhod's theorem, let Y_n and Y be random variables from the common probability space with distributions D'_n and D' , respectively. Thus, Y_n converges to Y almost surely, denoted by $Y_n \xrightarrow{a.s.} Y$, and D'_n converges to D' almost surely, denoted by $D'_n \xrightarrow{a.s.} D'$. Assume that Z_i and Z_i^* are independent and identically distributed random variables. Thus, $T(X, X^*, \mu, \sigma^2) \rightarrow D'^*$, where $D'^* = \max_{i \neq l} \left| (Z_i^* - Z_l^*) / \sqrt{\sigma_i^2/r_i + \sigma_l^2/r_l} \right|$, for $i, l = 1, 2, \dots, k$, and $i \neq l$.

Since the limiting distribution of $T(X, X^*, \mu, \sigma^2)$ is continuous and $z_{\alpha/2}(X) \rightarrow q_{\alpha/2}$, where $q_{\alpha/2}$ is the $\alpha/2$ -th quantile of the distribution of D'^* , we can obtain

$$P(D'_n \leq z_{\alpha/2}) \rightarrow P(D' \leq q_{\alpha/2}) = P(D'^* \leq q_{\alpha/2}) = 1 - \alpha,$$

as $n \rightarrow \infty$. Therefore,

$$P\left[v_{il} \in \left(\hat{v}_{il} \pm z_{\alpha/2} \sqrt{\widehat{Var}(\hat{v}_i) + \widehat{Var}(\hat{v}_l)}, \forall i \neq l\right)\right] \rightarrow 1 - \alpha,$$

which implies that

$$P(L_{il} \leq v_{il} \leq U_{il}, \forall i \neq l) \rightarrow 1 - \alpha.$$

□

Algorithm 2: For MOVER

Step 1. Generate random samples $X_i, i = 1, 2, \dots, k$ with sample size n_1, n_2, \dots, n_k and calculate $\hat{\delta}_{i(1)}$ and $\hat{\sigma}_i^2$.

Step 2. Generate $\chi_{1-\alpha/2, n_{i(1)}-1}^2, \chi_{\alpha/2, n_{i(1)}-1}^2$, and $Z_i \sim N(0, 1)$.

Step 3. Calculate $l_{\sigma_i^2}, l_{\sigma_i^2}, u_{\sigma_i^2}, u_{\sigma_i^2}, l_{\delta_{i(1)}}, l_{\delta_{i(1)}}, u_{\delta_{i(1)}},$ and $u_{\delta_{i(1)}}.$

Step 4. Repeat Steps 2–3 5,000 times.

Step 5. Compute the 95% SCIs for v_{il} .

Step 6. Repeat Steps 1–5 15,000 times.

SIMULATION RESULTS

Here, the performances of the proposed methods via Monte Carlo simulation with the R statistical program are presented. The best method attains a coverage probability equal to or greater than the nominal simultaneous confidence level of 0.95 together with the shortest expected length. The simulations were conducted with 15,000 iterations for each combination of parameters. Furthermore, 5,000 replications for the FGCI and Bayesian methods for each case of parameter combination were carried out. Sample sizes were set as 25, 50, and 100; $\delta_{i(1)} = 0.2, 0.5, 0.8$; and $\sigma_i^2 = 0.5, 1.0, 2.0$.

The results in Tables 2 - 4 and Figs. 1 - 3 show that the coverage probabilities of FGCI and the equal-tailed Bayesian using Jeffreys' rule prior were close to or greater than the nominal confidence level for almost all k values. Similarly, the coverage probabilities of the equal-tailed Bayesian using the uniform prior, the Bayesian credible intervals using Jeffreys' rule and uniform priors, and MOVER were close to or greater than the nominal confidence level for all cases. For most cases, the Bayesian credible interval using Jeffreys' rule prior attained the shortest expected length, except for $n_i = 50$; $\delta_{i(1)} = 0.5, 0.8$; and $\sigma_i^2 = 0.5, 1.0$, for which the expected lengths of FGCI were the shortest.

EMPIRICAL STUDY

Thailand is generally divided into five areas by topography, i.e. Northern (A1), Northeastern (A2), Central (A3), Eastern (A4), and Southern (A5). The daily rainfall data from these areas in August 2020 were used to assess the performances of the proposed methods for SCI construction. The distributions of these data are presented in Fig. 4, which shows right-skewness for all of the datasets. Thus, the minimum Akaike information criterion (AIC) and the lowest Bayesian information criterion (BIC) were used to test the fitting of the distributions to such data. From AIC and BIC results in Table 5, it is evident that the positive values in the rainfall datasets from the five areas conform to lognormal distributions. Moreover, normal Q-Q plots were constructed to show the distributions of the log-transformed positive rainfall data from the five areas (Fig. 5), which verified the AIC and BIC results that these datasets follow lognormal distributions. A summary of these data are

$$\begin{aligned} n_1 &= 31, \hat{\delta}_1 = 0.7097, \hat{\mu}_1 = 0.7715, \hat{\sigma}_1^2 = 3.4565, \hat{\eta}_1 = 6.6088, \\ n_2 &= 31, \hat{\delta}_2 = 0.6774, \hat{\mu}_2 = 1.4332, \hat{\sigma}_2^2 = 2.9550, \hat{\eta}_1 = 5.2294, \\ n_3 &= 31, \hat{\delta}_3 = 0.6452, \hat{\mu}_3 = 1.5512, \hat{\sigma}_3^2 = 2.8638, \hat{\eta}_3 = 5.1154, \\ n_4 &= 31, \hat{\delta}_4 = 0.4839, \hat{\mu}_4 = 1.4178, \hat{\sigma}_4^2 = 2.1487, \hat{\eta}_4 = 4.0888, \\ n_5 &= 31, \hat{\delta}_5 = 0.4839, \hat{\mu}_5 = 1.8040, \hat{\sigma}_5^2 = 2.1962, \hat{\eta}_5 = 4.1930. \end{aligned}$$

Table 6 reports the 95% SCIs and credible intervals for all pairwise differences between the CVs of the daily rainfall series from five areas in Thailand. The results show that the expected length of the Bayesian credible interval using the Jeffreys' rule prior was the shortest, which corresponds with the simulation results. Therefore, it is a good choice for constructing the SCI for all of the pairwise differences between the CVs of the precipitation series from the five areas in Thailand.

Table 2. The coverage probabilities and expected lengths for the 95% SCIs and credible intervals for all pairwise differences between the CVs of delta-lognormal distributions for $k = 3$.

DISCUSSION

The simulation results indicate that the Bayesian credible interval using Jeffreys' rule prior outperformed the other methods in virtually all cases. Although the coverage probabilities in some cases were close to 1.00, suggesting that overestimation may have occurred, the expected lengths were the shortest. Therefore, the Bayesian credible interval using Jeffreys' rule prior can be used to construct the SCIs for all of the pairwise differences between the CVs of delta-lognormal distributions. Since constructing SCIs concerns the differences between the parameters of interest for all pairwise comparisons, our findings correspond with Yosboonruang et al. (2020) who found that the highest posterior density Bayesian using Jeffreys' rule prior is appropriate for constructing the confidence interval for the difference between two independent CVs of delta-lognormal distributions. However, Abdel-Karim (2015) and Thangjai et al. (2019) reported that MOVER is the most suitable for constructing SCIs for the mean or CV of a lognormal distribution, but this is not in agreement with our findings for the data and scenario used in this study since the range of intervals for its SCI was wider than when using the Bayesian methods. In addition, the SCI range between the CVs of the daily rainfall data series from the five different areas of Thailand was too wide, and so this demonstrates that it is different in rainfall dispersion from five areas in Thailand.

CONCLUSIONS

Herein, we proposed methods to construct the SCIs for all pairwise differences between the CVs of delta-lognormal distributions, including FGCI, two Bayesian methods constructed under the equal-tailed confidence intervals and credible intervals using the Jeffreys' rule and uniform priors, and MOVER. The performances of the proposed methods were determined via their coverage probabilities together with their expected lengths under various circumstances. The results indicate that the Bayesian credible interval using the Jeffreys' rule prior was suitable for constructing the SCIs for all pairwise differences between the CVs of delta-lognormal distributions in terms of the coverage probability together with the expected length. Furthermore, FGCI is appropriate for constructing these SCIs in cases of the variances equal to 0.5 and 1.0 with the proportion of non-zero values equal to 0.5 and 0.8 for the sample sizes of 50 and 100. In addition, the results of using daily rainfall data from five regions in Thailand coincided with those from

the simulation study.
