# Playing with heart and soul...and genomes: Sports Implications and Applications of Personal Genomics

Whether the integration of genetic/omic technologies in sports contexts will facilitate player success, promote player safety, or spur genetic discrimination depends largely upon the game rules established by those currently designing genomic sports medicine programs. The integration has already begun, but there is not yet a playbook for best practices. Thus far discussions have focused largely on whether the integration would occur and how to prevent the integration from occurring, rather than how it could occur in such a way that maximizes benefits, minimizes risks, and avoids the exacerbation of racial disparities. Previous empirical research has identified members of the personal genomics industry offering sports-related DNA tests and previous legal research has explored the impact of collective bargaining in professional sports as it relates to the employment protections of the Genetic Information Nondiscrimination Act (GINA). Building upon that research and upon participant observations with specific sports-related DNA tests purchase from four direct-to-consumer companies in 2011 and broader personal genomics (PGx) services, this anthropological, legal, and ethical (ALE) discussion highlights fundamental issues that must be addressed by those developing personal genomic sports medicine programs, either independently or through collaborations with commercial providers. For example, the vulnerability of student athletes creates a number of issues that require careful, deliberate consideration. More broadly, however, this ALE discussion highlights potential sports-related implications (that ultimately might mitigate or, conversely, exacerbate racial disparities among athletes) of whole exome/genome sequencing conducted by biomedical researchers and clinicians for non-sports purposes. For example, the possibility that exome/genome sequencing of individuals who are considered to be non-patients, asymptomatic, normal, etc. will reveal the presence of variants of unknown significance in any one of the genes associated with hypertrophic cardiomyopathy (HCM), Long QT syndrome (LQTS), Marfan's syndrome, and other conditions is not inconsequential and how this information is reported, interpreted, and used may ultimately prevent the individual from participation in competitive sports. Due to the distribution of genetic diversity that reflects our evolutionary and demographic history (including the discernible effects of restricted gene

flow and genetic drift associated with cultural constructs of race) and in recognition of previous policies for "leveling" the playing field in competitive sports based on "natural" athletic abilities, preliminary recommendations are provided to discourage genetic segregation of sports and to develop best practice guidelines for genomic sports medicine programs that will facilitate player success, promote player safety, and avoid genetic discrimination within and beyond the program.

1 **Playing with Heart and Soul…and Genomes: Sports Implications and Applications of**

2 **Personal Genomics**

4 *Introduction*

5     In March 2013 the American College of Medical Genetics and Genomics (ACMG) and

6 the American Academy of Pediatrics (AAP) announced a policy statement on genetic testing and

7 screening of children (Friedman Ross et al. 2013). As shown in Table 1, the AAP and ACMG

8 jointly and unequivocally opposed a number of practices regarding minors, including

9 school-based genetic screening or testing, routine carrier screening for recessive conditions (such

10 as sickle cell carrier status), and direct-to-consumer testing. Similarly, the AAP and ACMG

11 cautioned against the expansion of newborn screening, warning that such practices may "give

12 rise to 'patients in waiting': individuals with a genetic diagnosis who have no signs or symptoms

13 and may remain asymptomatic for years or decades." The need for genetic counseling was

14 highlighted, specifically in the context of predictive testing (i.e. testing for "the presence of a

15 mutation that will almost certainly give rise to clinical manifestations"), with the AAP and

16 ACMG noting that such counseling is "essential to ensure that parents, guardians, and maturing

17 minors fully understand the limits of genetic knowledge and treatment capabilities as well as the

18 potential for psychological harm, stigmatization, and discrimination." The AAP and ACMG also

19 took positions on access to testing, timing of testing, and access to test results, as shown in Table

20 2, recognizing parents and children may have differing opinions. In doing so, the organizations

21 emphasized the need to focus on the best medical interests of the child but recognized those

22 interests are "embedded in and dependent on the interests of the family unit."

23     Also in March 2013, the ACMG announced age-neutral recommendations (Green et al.

24 2013) for reporting of incidental findings in exome and genome sequencing (WES/WGS).

25 Prompted by criticisms and perhaps also confusions (e.g. Heger 2013), the ACMG issued

26 clarifications shortly thereafter (ACMG 2013). Notwithstanding the positions the ACMG

27 affirmed with its joint statement with the AAP, the ACMG recommended the minimum reporting

28 of incidental findings of any variants previously reported as "known" or "expected" to be

29 pathogenic –regardless of the well-documented publication bias of positive results in the

30 academic literature and regardless of the individual's health—in "a set of 57 carefully chosen

31 genes for pathogenic mutations that could indicate the presence of any of 24 disorders where

1                                                                                                          1

32  early intervention is likely to reduce or prevent serious morbidity or early mortality" (Green et al.

33  2013). The ACMG reaffirmed its concerns regarding an emerging class of "patients in waiting"

34  who may face significant psychological burdens and exposure to unnecessary surveillance and

35  diagnostic testing as the result of learning about incidental findings from WES/WGS. While the

36  ACMG clarified that WES/WGS specifically of youth should be performed "only if there are

37  clear clinical indications," the organization noted that this recommendation to report to youth

38  incidental findings of "a severe, actionable, pathogenic mutation" is not contradictory to or

39  inconsistent with the organization's prior recommendation made with the AAP (ACMG 2013).

41  ***Sports Implications of Genomic Research and Medicine***

42  As shown in Table 3, among the 57 genes on the ACMG's list for reporting of variants

43  are a number of genes involved with cardiac conditions, including 11 genes reported to cause

44  Hypertrophic Cardiomyopathy (HCM), three genes reported to cause Long QT Syndrome

45  (LQTS), and seven genes reported to cause Marfan Syndrome (MFS) and related disorders.

46  HCM (OMIM #192600) has an estimated prevalence of 1 in 500. The condition is

47  clinically variable and genetically heterogeneous. At least 18 genes have been reported, including

48  the 11 genes included on the ACMG list for reporting of incidental findings. Roughly 60-70% of

49  cases of HCM are due to mutations in one or more of the 18 genes. Reliably distinguishing

50  pathogenic variants from variants of unknown significance (VUS) and non-pathogenic variants

51  in these genes presents a major challenge for genomic medicine (Maron, Maron, and Semsarian

52  2012). Notably, roughly 50% of adults diagnosed with HCM have a family history of either

53  HCM or sudden death at a young age (e.g. GeneDx 2011a). HCM is the leading cause of sudden

54  cardiac arrest in young individuals and athletes (e.g. Maron et al. 2009).

55  LQTS (OMIM #192500) has an estimated prevalence of more than 1 in 3000.

56  Approximately 75% of the cases of LQTS are due to known genetic mutations. Like HCM,

57  LQTS is genetically heterogeneous: while three genes are on the ACMG's minimum list for

58  reporting of incidental findings, more than 12 genes have been reported. Moreover, mutations

59  have shown incomplete penetrance, and LQTS has variable expressivity even within families.

60  Some individuals with LQTS show no clinical symptoms; however, for approximately 10-15%

61  of individuals diagnosed with LQTS, the first symptom is sudden death. While individuals with

62  LQTS may experience fainting or heart palpitations with exercise, others may experience such

2                                                                                                                    2

63    events while at rest or upon auditory stimulation (e.g. GeneDx 2011b).

64          MFS (OMIM #154700), estimated to have a worldwide prevalence of 1 in 3000-5000, is

65    a connective tissue disorder involving *FBN1*, a gene marked by considerable pleiotropy (e.g.

66    Pyeritz 2002). Expression is highly variable, but clinical features may include tall stature with

67    disproportionately long limbs, joint hypermobility, ectopia lentis, myopia, mitral valve prolapse,

68    aortic dissection, and aortic root dilation (among others). Genetic testing is considered important

69    to identify pre-symptomatic individuals who could benefit from surveillance (e.g. GeneDx

70    2012).

71          Suspected and/or confirmed diagnosis of any of these conditions (HCM, LQTS, or MFS

72    and related disorders) has serious implications for an individual's future eligibility for

73    participation in competitive athletics (even when the individual is asymptomatic). Many experts

74    and policymakers are convinced by anecdotal evidence suggesting that restriction of physical

75    activity is an appropriate measure to prevent sudden cardiac death (SCD) among individuals with

76    one of these conditions (see, e.g., Maron and Zipes 2005). Empiric data, however, are

77    contradictory as to whether moderate to rigorous physical activity has beneficial or adverse

78    effects on risk of SCD (e.g. Deo and Albert 2012). Additionally, a broad restriction on athletic

79    participation overlooks the variation of the static and dynamic components required of different

80    sports that may confer differential risks of SCD (Vaseghi, Ackerman, and Mandapati 2012).

81    There is a dearth of empiric data demonstrating that individuals with such genetic variants in

82    genes reported for HCM, LQTS, MFS or related conditions who participate in competitive sports

83    have higher risks of SCD than those individuals with the same genetic variants who refrain from

84    participation in competitive sports. Notably, Hoffman and colleagues (2012) have reported that

85    an *FBN1* mutation is not itself a predictor for SCD, and O'Mahony and colleagues (2013) have

86    described the difficulties and limited power of risk stratification algorithms designed to identify

87    those individuals diagnosed with HCM who are at a high risk of SCD.

88          Preventing sudden cardiac death in athletes is a high priority. As Angelini et al. (2013)

89    noted,

90          "…[A]t present, it is probably reasonable to assume that 2% to 3% of the general
91          population has cardiovascular conditions…that seem to pose a high risk to
92          competitive sportspersons. Considering that the young population constitutes
93          approximately 28% of the total United States population, or about 90 million, the
94          2% to 3% would correspond to about 2 million people. If we consider only the
95          estimated 1.5 to 10 million "young athletes" in the U.S. (usually defined as

3                                                                                              3

96    "regular runners") in any given year, 30,000 to 300,000 of them would be
97    expected to carry high-risk cardiovascular conditions (hr-CVCs). Preliminary
98    estimates suggest that 0.1 to 0.6 per 100,000 young people die suddenly of cardiac
99    causes each year, whereas 2 to 7 per 100,000 U.S. athletes die in that manner."
100

101    SCD is the leading cause of death and death during exercise of NCAA student-athletes, with an

102    incidence of 1 in 43,000 student-athletes per year (Harmon et al. 2011). HCM, involved in 36%

103    of cases, is the leading cause of SCD of U.S. athletes (Maron et al. 2009). Sex and racial

104    disparities have been reported by Harmon et al. (2011), noting SCD among male student-athletes

105    was 2.3x more common than among female student-athletes and further noting the incidence of

106    SCD in Black student-athletes was 3x that of White student-athletes. Moreover, SCD rates vary

107    by sport, with SCD most common in basketball, football, swimming, lacrosse, and cross-country.

108    Prevalence of risk factors for SCD has been reported as roughly 3 in 1000 (see Harmon et al.

109    2011).

110         Tragic sudden cardiac deaths of youth athletes—such as 16 year old Michigan high

111    school basketball player Wes Leonard (e.g. Moisse 2011), 17 year old Colorado high school

112    rugby player Matthew Hammerdorfer (e.g. Sandell and Dolak 2011), 16 year old California high

113    school swimmer Justin Carr (e.g. Sondheimer 2013), and 23 year old Pennsylvania runner Kyle

114    Johnson (e.g. SCA Foundation 2013, Zimmerman 2013)—grab local and national attention and

115    often prompt calls for stronger protections of youth athletes. Pre-participation screening of

116    athletes has been criticized for being too weak. Lisa Salberg, CEO of the Hypertrophic

117    Cardiomyopathy Association (HCMA), has been a vocal critic of current screening practices

118    stating, "As parents, we encourage our children to participate in athletics and organized sports,

119    however are we doing enough to ensure that they are healthy enough to be playing?" (Hirschhorn

120    2010). Other criticisms focus on the response to such sudden cardiac arrest emergencies when

121    they do occur: public health advocates call for increased availability of automatic external

122    defibrillators at sporting venues and highlight "success" stories such as that of Davis Nwankwo,

123    a Vanderbilt basketball player who collapsed on the court during practice in 2006 but whose life

124    was saved by his athletic trainer armed with an automatic external defibrillator (e.g. Sayre 2011).

125    The Sudden Cardiac Death of the Young Surveillance and Prevention Project of the Michigan

126    Department of Community Health Genomics Program (See MDCH 2012) has been productive in

127    studying the problem from many angles and has identified 21 action steps in five areas of need to

4                                                                                          4

128    prevent SCD, including improvement of pre-participation sports screening, training in the use of

129    AEDs and performance of CPR, education/awareness of SCD, and both emergency response and

130    medical examiner protocols (Duquette and Anderson 2012).

131         Pre-participation educational/awareness and screening programs may provide important

132    opportunities to get the public's attention on heart health issues. Cascade genetic screening (i.e. a

133    process wherein first degree relatives are screened after a mutation has been identified in a

134    proband) has been touted for its ability to identify carriers who may be asymptomatic or

135    pre-symptomatic and who may benefit from early implementation of surveillance and therapeutic

136    efforts (such as use of implantable defibrillators) (e.g. Ackerman et al. 2011). However, it is

137    important to note the sports implications of identifying genetic variants in asymptomatic or

138    pre-symptomatic individuals who currently have or may in the future have interests in

139    competitive sports. Is identifying such genetic variants a means to ensure player safety or simply

140    a means of facilitating systematic genetic discrimination? While expanding access to genetic risk

141    information is critically important for prevention of SCD, numerous legal and ethical challenges

142    lurk in the ways in which genetic risk information flows among the various actors in the sports

143    context (e.g. from an individual athlete to the athlete's parents, heath care providers, trainers,

144    coaches, administrators, player's agents, team's scouts, league officials, media, spectators,

145    boosters, etc.) as well as the way in which decisions are made relying upon that genetic

146    information (ranging from absolute assumption of risks versus involuntary disqualification from

147    participation). Numerous influences suggest that the individual athlete will *not* be in control of

148    the decision to engage in competitive sports once one or more genetic risk variants is/are

149    discovered – regardless of whether that discovery occurs during participation in genomic

150    medicine and research completely unrelated to sports or during pre-participation screening

151    specifically for sports.

152         For example, Pennsylvania recently adopted the Sudden Cardiac Arrest Prevention Act

153    (24 P.S. §5331 *et seq.*, P.L. 574, No. 59 §1, effective July 30, 2012). This statute provides that a

154    student-athlete must be removed from play and prevented from returning to play if the individual

155    "is known to have exhibited *signs or symptoms* of sudden cardiac arrest *at any time* prior to or

156    following an athletic activity…" (24 P.S. §5333(c)(2)). The statute prohibits the individual's

157    return to athletic activity "until the student is evaluated and cleared for return to participation in

158    writing by a licensed physician, certified nurse practitioner, or cardiologist" (24 P.S. §5333(c)

5                                                                                                    5

159   (3)). While genetic counselors are notably omitted from this list, the statute permits those

160   authorized to provide return-to-play clearances to consult other "licensed or certified medical

161   professionals," which would include genetic counselors. This is because Pennsylvania is among

162   the states that have passed bills requiring genetic counselors to be a licensed medical profession

163   (63 P.S. § 422.13d, P.L. 576, No. 125 §2, effective February 21, 2012; See also Wagner 2012).

164   The Sudden Cardiac Arrest Prevention Act does not define "signs or symptoms," and ordinary

165   parsing of the statute's text indicates "signs" has different meaning from "symptoms."

166   Otherwise, the terms "signs" and "symptoms" are redundant and "or" is meaningless. Thus, it is

167   possible (if not likely) that those who must comply with the Sudden Cardiac Arrest Prevention

168   Act (i.e. public school officials, their coaches, and those medical practitioners making clearance

169   determinations) will interpret the statute in such a way that the presence of a genetic variant

170   –regardless of the presence or absence of symptoms expressed by the individual– would

171   constitute a "sign" that precludes the individual from participation. A survey of the legislative

172   activity, shown in Table 4, revealed at least 10 states that are presently considering similar

173   legislation to Pennsylvania's Sudden Cardiac Arrest Prevention Act.

174         Moreover, the American College of Cardiology (ACC) Bethesda Conference #36 provide

175   specific recommendations regarding eligibility and disqualification of competitive athletes

176   (Maron and Zipes 2005; See also Pelliccia et al. 2008; Maron et al. 2009). Bethesda Conference

177   #36 Guidelines include extensive discussion on HCM, LQTS, MFS and related cardiac

178   conditions. Relevant guidelines are shown in Table 5. These guidelines generally recommend

179   restricting individuals from participation in competitive sports. It is uncertain how the Bethesda

180   Conference #36 Guidelines are intended by the ACC to be applied in cases where the diagnosis

181   of the HCM, LQTS, MFS or related condition is made using a genomic medicine approach

182   available today. While the Bethesda Conference #36 Guidelines note that, at the time the

183   guidelines were drafted, genotype alone did not warrant disqualification from competitive sports,

184   the subsequent biomedical literature and the 2013 ACMG recommendations on reporting

185   incidental findings may contribute to medical professionals making cautious (perhaps overly

186   cautious or paternalistic) medical clearance decisions. Empirical data regarding how medical

187   professionals are currently making sports clearance decisions in light of genomic medicine and

188   research advances and recent legislative and policy activities are not yet available.

189         The purpose of pre-participation screening is "to provide potential participants with a

190  determination of medical eligibility for competitive sports that is based on evaluations intended

191  to identify (or raise suspicion of) clinically relevant, preexisting abnormalities" (Maron et al.

192  2007). Screening is for "the identification of at-risk athletes and the prophylactic prevention of

193  cardiac events during sports by selective disqualification" (Maron et al. 2007). Medical

194  professionals providing eligibility certification and making determinations of disqualification are

195  expected to follow the American Heart Association (AHA) recommendations for student-athletes

196  (at both high school and collegiate levels), and failure to comply may expose the medical

197  professional to malpractice liability for an athlete's death or injury caused by an abnormality that

198  would have been discovered had the guidelines been followed (Maron et al. 2007). While the

199  AHA recommendations require pre-participation screening to consider personal history, family

200  history, and physical examination (see Table in Maron et al. 2007), they have not required

201  12-lead electrocardiograms (ECG) or genetic screening (such as those panels offered by GeneDx

202  for HCM, LQTS, and MFS and related conditions). Genetic screening for HCM was considered

203  but rejected due to its cost, genetic heterogeneity, and the anticipated frequency of false-negative

204  results (Maron et al. 2007). Given the nuances of the current biomedical understanding of

205  various cardiac conditions (including HCM, LQTS, MFS and related conditions), genetic risk

206  information is *informative* but far from *determinative* of a player's health and corresponding

207  risks of SCD. Accordingly, it seems unwise to base decisions of athletic eligibility (particularly

208  eligibility of those individuals who are asymptomatic or pre-symptomatic) on the presence of a

209  genetic variant alone – even if such genetic variants are covered by the ACMG's recommended

210  list for reporting of incidental findings.

211

212  ***Facilitating Player Safety or Genetic Discrimination?***

213       Together, the ACMG recommendations for reporting incidental findings, the Sudden

214  Cardiac Arrest Prevention Act in Pennsylvania (and similar state bills if adopted), the Bethesda

215  Conference #36 Guidelines, and general aversions to tort liability risks (e.g. medical malpractice)

216  will work together in a conservative, paternalistic manner. Undoubtedly such efforts may

217  promote *individual* safety; however, it would be inaccurate to characterize these efforts as

218  promoting *player* safety. Ultimately the majority of individuals "protected" will not be permitted

219  to be players at all, since adequate medical clearance paperwork will be hard to come by.

220  Pre-participation screening practices that serve to disqualify individuals from participation in

7                                                                                                 7

221 sports as a result of family medical history or genetic information when they themselves are

222 asymptomatic is genetic discrimination (specifically, systematic disparate treatment).

223 Notably, racial disparities exist in sports contexts, including disparate participation in

224 specific sports and in specific positions in team sports (e.g. Graves 2005). Racial disparities exist

225 among athletes as well as among executives/decision-makers. For example, racial minorities

226 represent more than two-thirds (69%) of all NFL players but hold few positions of authority, with

227 racial minorities representing 0% of CEOs/presidents; 3% of majority ownership; < 20% of head

228 coaches or general managers; and < 15% of physicians and head trainers (Lapchick et al. 2012).

229 The disproportionate participation may be reversed in other sports (e.g. skiing and snowboarding

230 (e.g. Eiss 2011)). Many factors contribute to existing disparities in sports (e.g., sociocultural

231 factors of differential power, wealth, and prestige given to sports, self-selection biases; economic

232 factors influencing access to educational, nutritional, and training resources; environmental

233 factors including in utero exposures; and genetic factors). The existing disparities are an

234 important aspect of the context in which genetic/omic technologies are being integrated in sports

235 training and medicine programs. Understanding this context is essential when evaluating

236 potential challenges arising from this integration of genetic information in sports and the

237 development of "genomic sports medicine." The genomic revolution has the potential to alleviate

238 or exacerbate racial disparities depending upon how the integration is executed. Enhancing the

239 awareness and understanding of genetic risks and increasing access to health information through

240 pre-participation screening for sports is a means to reach under-served minority populations.

241 However, that health opportunity could translate into employment discrimination, quashing

242 future professional sports employment opportunities via disproportionate selective

243 disqualifications and, in the process, create life-changing psychological, social, professional, and

244 economical impacts within members of those under-served minority populations.

245

246 ***Sports-Related Genetic/omic Screening***

247 The integration of genetic/omic technologies in sports contexts is not a hypothetical

248 concept. Various renditions have already been attempted both domestically and internationally

249 for diverse purposes (Wagner 2013). Lawsuits can be strong motivators for the adoption of DNA

250 screening policies. Such efforts promote safety by identifying risks prior to participation, but

251 screening efforts also serve to limit liability exposure of the event organizers, the leagues, the

252  teams, the schools, etc. Such was the case for the NCAA's adoption of sickle cell carrier

253  screening. The NCAA sickle cell screening policy arose as part of a settlement agreement

254  resolving a lawsuit that followed the death of Dale Lloyd II, a 19 year old football player at Rice

255  University. The student-athlete died from acute exertional rhabdomyolysis (a complication of

256  sickle cell trait) after collapsing on the field upon running a 100-yard sprints (e.g. Zarda 2010).

257  The NCAA implemented the screening policy notwithstanding criticism and opposition from the

258  American Society of Hematology (ASH), as the ASH favors universally applicable safety

259  policies to help athletes regardless of sickle cell carrier status (e.g. Petrochko 2012). The NCAA

260  subsequently expanded its screening program beyond Division I athletes to include athletes in

261  Divisions II (Hendrickson 2012) and III (Brown 2013).

262       Genetic screening may be forthcoming for concussion risks (e.g. APOE ε4), if the NFL

263  adopts concussion screening as part of settlement agreements for pending lawsuits involving

264  more than 4200 players (*In Re: National Football League Players' Concussion Injury Litigation*;

265  See also Anderson 2013) or if the NCAA reacts to the American Academy of Neurology updated

266  guidelines naming APOE as a risk factor for chronic neurobehavioral impairment (Giza et al.

267  2013) and expands its screening program beyond sickle cell carrier status. Some have already

268  suggested compulsory brain scans and genetic testing for boxers and others have suggested

269  banning such sports altogether (e.g. Jordan 1998; Springs 2004; Kelland et al. 2013). At least one

270  company that had provided sports-related personal genomics services DTC (Athleticode) has

271  repositioned itself to focus specifically on concussion risks.

272       Genetic screening may also be forthcoming for HCM risks (e.g. MYH7, MYBPC3, and

273  TNNT2) as sudden cardiac deaths of seemingly healthy youth (e.g. most recently Kyle Johnson)

274  prompt public calls for pre-participation screening. As mentioned earlier, about one-third of

275  athletic field deaths in the United States are caused by HCM, an abnormal thickening of the

276  ventricular walls of the heart muscle (Maron 2005). Screening for HCM has been advocated not

277  to promote safety of those engaged in athletics but, rather, to identify and disqualify individuals

278  prior to participation (e.g. Corrado et al. 1998). Distinguishing potentially life-threatening HCM

279  from "athlete's heart," a non-pathological condition resulting from intense training, is quite

280  challenging (E.g. Maron 2005, Cheng 2009; Creswell 2009). Despite potential false negatives,

281  genetic testing is the "most definitive way" to distinguish HCM from athlete's heart (Cheng

282  2009). While more than 1000 distinct mutations have been identified, the mutations found within

9                                                                                                          9

283  two genes (MYH7 and MYBPC3, OMIM #160760 and #600958, respectively) collectively

284  account for more than 75-80% of HCM (Ho 2011). In 2010 a jury granted an award of $1.6

285  million dollars to the parents of Antwoine Key, a 22 year old basketball player for Eastern

286  Connecticut State University who collapsed and died as a result of undiagnosed HCM. The

287  student-athlete had been given clearance to play by five different physicians notwithstanding a

288  heart murmur noted during a pre-participation exam more than three years prior to his collapse

289  (*Key v. Abdulah;* See also Morlan 2010; Hirschhorn 2010).

290

291  ***Moving Toward Athlete-Initiated Integrations of Personal Genomics in Sports***

292  Personal genomics (PGx) services of varying scope and quality (in terms of analysis,

293  return of results, and interpretations) are now available direct-to-consumers. These PGx services

294  include and sometimes focus on traits and conditions relevant to sports (Wagner 2013; Wagner

295  and Royal 2012; Wagner and Royal, unpublished data), allowing individual athletes to access

296  information (a) without coordination with a school, team, or perhaps even parents and (b)

297  specifically outside of the formal and potentially intimidating context of medical care, scientific

298  research, and pre-participation screening processes. Among the ~250 genetic variants implicated

299  in sports-related phenotypes (Rankinen et al. 2010; Bray et al. 2009; Rankinen et al. 2006;

300  Wolfarth et al. 2005; Rankinen et al. 2004; Perusse et al. 2003; Rankinen et al. 2002; Rankinen et

301  al. 2001) are *ACTN3, COL5A1, COL12A1, COL1Al, GDF5, ACE, ADRB2, PPARGC1A, MMP3,*

302  *APOE, MYH7, MYBPC3, TNNT2, DIO1, NOS3, IL6, VEGFR, HIF1, MCT1, EPOR,* and *SCN5A,*

303  all of which have been available as part of one or more DTC sports-related genetic tests (Wagner

304  and Royal 2012). Many of these genetic variants have been characterized as "gene doping

305  targets" (Azzazy et al. 2009) or "candidate genes for sport doping" that will enable "the creation

306  of a superman or superwoman athlete" through "well-placed genetic physiologic tweaks"

307  (Gaffney and Parisotto 2007). However, anthropological geneticists have cautioned that genotype

308  is not the full explanation of "what makes a champion," as there are many potential confounders,

309  including spurious associations due to population structure or ancestry and the complex and

310  varying effects of gene-environment interactions over an individual's lifetime (Brutsaert and

311  Parra 2006).

312  It is evident that the sports-related sector of the larger PGx industry has considerable

313  potential for diversity in terms of phenotypes of interest and genetic loci assayed. Previous

10                                                                                                    10

314  research identified the companies in the sports-related PGx industry and analyzed information

315  provided online to prospective consumers (Wagner and Royal 2012). An empiric investigation

316  involving participant observation and the purchase of four sports-related DNA tests in 2011

317  (Wagner and Royal, unpublished data) revealed that there is, in fact, considerable diversity in

318  offerings and that there simply is no "typical" or "standard" sports-related DTC panel for the

319  PGx industry (See Table 6). PGx offerings for genetic information related to power or strength

320  have focused on *ACTN3* (rs1815739, OMIM #102574), *IL6* (rs1800795, OMIM #147620), and

321  *DIO1* (rs11206244 and rs12095080, OMIM #147892). For endurance, PG offerings have focused

322  on *NOS3* (rs2070744 and rs1799983, OMIM #163729), *HIF1A* (rs11549465, OMIM #603348),

323  *MCT1* (rs1049434, OMIM #600682), *VGFR* (OMIM #191306), and *EPOR* (rs121918116,

324  OMIM #133171). PGx offerings for soft tissue injury risks have focused on *MMP3* (rs679620,

325  rs591058, rs650108, OMIM #185250), *COL5A1* (rs12722, OMIM #120215), *COL12A1*

326  rs970547, OMIM #120320), *COL1A1* (rs1800012, OMIM #120150), and *GDF5* (rs143383,

327  OMIM #601146). For cardiac risks, PGx offerings have focused on MYH7 (OMIM #160760),

328  MYBPC3 (OMIM #600958), and SCN5A (rs7626962, OMIM #600163). PGx offerings have

329  even included concussion risks, focusing on APOE (OMIM #107741). Upon closer examination,

330  it is apparent that AIBiotech has provided access to a number of genes on the ACMG's

331  recommended incidental findings report: AIBiotech has provided exome sequencing of *MYH7*,

332  *MYBPC3*, and *TNNT2* (three of the genes related to HCM risks) and testing of *SCN5A* (a gene on

333  the ACMG's list of recommended reporting for LQTS and related acquired arrhythmias).

334  *SCN5A*, a cardiac sodium channel gene with a number of common polymorphisms (OMIM

335  #600163) (Cheng 2011), contains a Y1002 variant (S1103Y, rs7626962) that is rare in European

336  Americans (Smith et al. 2011) but reported at allele frequencies ~13.2% in African Americans

337  (Splawski et al. 2002). This polymorphism reportedly causes a "small but inherent and chronic

338  risk of acquired arrhythmia" (Splawski et al. 2002).

339          While 23andMe is not focused on providing a sports-related service, its PGx analysis

340  does incorporate much of the information athletes could seek elsewhere. 23andMe provides

341  reports on muscle performance, response to diet, response to exercise, pain sensitivity, asthma,

342  sickle cell carrier status, heart rhythm disorders, and APOE4 status (though not reported for

343  concussion risk (see BethannH 2013)). The 23andMe's latest platform (version 3) has

344  considerable coverage of the recommended ACMG list shown previously in Table 3. Browsing

11                                                                                    11

345 raw data in 23andMe for the first three genes of each condition listed in Table 3, the PGx service

346 includes 33 SNPs in *MYBPC3,* 52 SNPs in *MYH7*, and 30 SNPs in *TNNT2* (three genes on

347 ACMG's list for HCM); 271 SNPs in *KCNQ1*, 50 SNPs in *KCNH2*, and 116 SNPs in *SCN5A*

348 (three genes on ACMG's list for LQTS and related arrhythmias); and 139 SNPs in *FBN1*, 26

349 SNPs in *TGFBR1*, and 75 SNPs in *TGFBR2* (three genes on ACMG's list for MFS and related

350 disorders). The consumer's or user's ability to download the raw data from 23andMe for

351 subsequent independent analysis and interpretation makes it attractive for individuals whose

352 motivations may include sports-related purposes.

353 Collegiate sports medicine and athletic programs are beginning to incorporate PGx as

354 well. One example is Dr. Stuart Kim's work to integrate PGx for injury risk prevention at

355 Stanford University (see https://sportsgenetics.stanford.edu/). The Stanford pilot program

356 focuses on secondary analysis and interpretation of 23andMe raw data files (version 3 platform)

357 to assess risks for stress fractures, ACL ruptures, Achilles tendinopathy, disc degeneration,

358 hemoglobin count, vitamin and mineral deficiencies, and osteoarthritis as well as sickle cell

359 carrier status. Participants upload their 23andMe raw data to the program's website and Dr. Kim

360 and his colleagues perform secondary analysis of the data. The program involves one-hour

361 consultations to discuss the results, and the idea is that athletes could modify their training

362 programs, take nutritional supplements (e.g. Vitamin D), and obtain additional medical services

363 to prevent disruptions to their athletic seasons due to injury. At least 15 elite athletes from the

364 Stanford Triathlon Club have participated thus far. This pilot program is expected to expand to

365 include the Varsity cross-country teams at Stanford and the University of California Los Angeles

366 before being proposed for adoption by the Pac-12 Conference at large (Personal communication

367 with Dr. Stuart Kim; March 15, 2013) and the program has also initiated recruitment of

368 endurance athletes in the San Francisco bay area.

369

370 ***Recognizing the Vulnerabilities of Student-Athletes***

371 Individuals with extraordinary athletic abilities are rarely thought of or described

372 as "vulnerable" (but see Davis 1998). Nonetheless, when considering the potential and probable

373 applications of PGx in sports contexts, a number of characteristics suggest the vulnerability (See,

374 e.g., Beauchamp and Childress 2009) of student-athletes. To ensure (1) respect for autonomy of

375 the student-athletes, (2) optimization of the risks and benefits, and (3) promotion of justice

12                                                                                    12

376  among student-athletes, recognition of these vulnerabilities suggests heightened care be

377  exercised when developing a program incorporating PGx technologies. These vulnerabilities of

378  student-athletes highlight potential reasons why a DTC market will and should continue to exist

379  (and why best practices should be promoted within the broader PGx industry), as individuals

380  interested in sports should have a means to access their own PGx information without other

381  actors (i.e. parents, coaches, league officials, medical providers, etc.) automatically and/or

382  simultaneously gaining unfettered access to those data.

383        First, student-athletes are often under the age of majority (i.e. 18 or 21 years of age),

384  which effectively limits the individuals' ability to enter into contracts or provide consent

385  independently and thereby perpetuates a state of dependency upon parents or guardians.

386  Regulatory protections for participation in research include the requirement that researchers

387  obtain not only informed assent from minors but corresponding informed consent from the

388  minors' parents or guardians. Considerable deference is given to parents in the U.S. to make

389  decisions in the "best interest of the child" (See, e.g., *Troxel v. Granville*). Nonetheless, parents

390  may hold extreme perspectives regarding PGx and/or sports that could impinge on the

391  student-athletes' ability to effectuate their needs and interests in this context. For example,

392  parents espousing genetic determinism could alternatively deny or compel their children to

393  obtain PGx information for sports purposes. Economic dependency of student-athletes further

394  exacerbates the potential compromise of autonomous decision-making by student-athletes who

395  are considering the use of PGx in sports contexts.

396        Coercive pressures to participate in any activity perceived to provide a competitive edge

397  along with the intensely competitive personalities of student-athletes create vulnerabilities for

398  student-athletes as well. While coercive pressures of the business of sports should be

399  acknowledged when present, they cannot be assumed *a priori* as undue influences that negate or

400  preclude voluntary consent from student-athletes. Red flags raised by existing coercive

401  pressures, however, suggest that recruitment procedures include education and outreach efforts to

402  explain clearly the details of the program and further suggest that a reasonable waiting period be

403  provided to ensure that decisions to participate are made deliberately and upon disclosure of

404  adequate information.

405        A third characteristic of vulnerability is the precarious status that student-athletes hold

406  under the Genetic Information Nondiscrimination Act (GINA). Title II of GINA prohibits

13                                                                                                13

407  employers and labor organizations from requesting or using genetic information in employment

408  decisions. As was previously examined elsewhere, sports employment is not exempted from

409  GINA Title II's prohibition on using genetic information to limit, classify, segregate employees

410  (i.e. players), and employers enjoy no defense for use of genetic information as a "bona fide

411  occupational qualification" (Wagner 2013). GINA coverage, however, does not clearly situate

412  student-athletes under the umbrella of a protected class. Rather, GINA protections extend only to

413  former employees, current employees, and prospective employees. Current amateur rules and

414  legal fictions combine forces in ways that undermine the general labor and genetic

415  nondiscrimination protections of student-athletes. In exchange for the opportunity for a position

416  on the team, the privilege to wear the uniform, and the benefits of education and scholarships,

417  student-athletes transfer any monetary benefits of their hard-earned labors to others (i.e. they

418  waive earnings) and must refrain from gainful employment elsewhere (i.e. they agree to

419  broad-sweeping non-compete covenants). Notwithstanding this exchange of ongoing benefits

420  and obligations, student-athletes are denied status as school "employees" (See, e.g., Maisel 2011;

421  McCormick and McCormick 2006; See also Branch 2011). While numerous arguments can be

422  made to extend GINA status as "current employees" (with schools as the covered entities) and as

423  "prospective employees" (with professional teams as the covered entities) to student-athletes for

424  purposes of GINA, this uncertain status exposes student-athletes to genetic discrimination as a

425  foreseeable consequence (a) of participation (or non-participation) in sports programs integrating

426  PGx (such as the Stanford program) and (b) of the application of genetic technologies in

427  pre-participation screening programs.

428      Finally, student-athletes are often treated with celebrity status (locally, regionally,

429  nationally, and internationally), creating privacy concerns. Privacy rights in the U.S. are

430  protected contextually (not with one broad-sweeping statute), and are balanced with other

431  interests (such as First Amendment freedoms of speech and association). While one need not

432  "live the life of a recluse" to enjoy privacy rights (Maxey 1937), celebrity status broadens that

433  which is newsworthy and is sometimes considered a waiver of some privacy rights (e.g. Hull v.

434  Curtis Publishing Co). The integration of genetic screening programs or use of PGx in sports

435  could undermine the individual's genetic privacy interests and expose the individual to a number

436  of future risks, including discrimination (See, e.g, Quick 2012).

437

14                                                                                                        14

438 *Conclusions*

439    While some may claim the limited scope of the ACMG recommendations (i.e.

440  WGS/WES in clinical settings) indicates that very few individuals would fit the problematic

441  scenario outlined here, that assumption is not supported by any data. Moreover, that assumption

442  fails to consider that those performing WGS/WES in non-clinical settings may, too, look to the

443  ACMG's recommendations for guidance on what the professional standard of conduct should be.

444  The possibility of discovering "incidental findings" in the ACMG's list of genes with WGS/WES

445  of normal, unaffected, or asymptomatic individuals is not negligible. Healthy individuals, as a

446  result, might be precluded from participation in sports unfairly as a result of the conservative

447  influences of the Sudden Cardiac Arrest Prevention Act in Pennsylvania (and similar state

448  statutes if adopted), the Bethesda Conference #36 Guidelines, and the broader medical

449  profession's aversion to tort liability risks. Even when medical clearances to play are provided by

450  medical professionals, genetic illiterate or genetic deterministic parents may serve as distinct

451  barriers for sports participation. Updated guidelines clarifying how the ACMG's recommended

452  list of reporting incidental findings should be reconciled with these conservative forces causing

453  medical professionals to err on the side of caution in sports contexts (i.e. disqualification or

454  restriction from athletic activity). It is possible that surveillance – not disqualification or

455  restriction from participation in competitive sports – is an appropriate measure for asymptomatic

456  individuals who happen to carry a variant in one of the genes noted in Table 3. Such an approach

457  acknowledges the public health interests in preventing sudden cardiac death but balances those

458  interests in a way that respects the individuals' personal interests in assuming the risks and

459  playing competitive sports notwithstanding the presence of a genetic risk variant. Individuals

460  will vary in their reactions to learning personal genetic information. Within reason, those

461  individual reactions and preferences for risk assumption should be respected.

462    When integrating genetic technologies into sports settings, it is absolutely essential that

463  the intended purposes and unintended consequences are carefully considered during program

464  development and that these are subsequently re-evaluated on a recurring basis throughout

465  implementation. While official guidelines for genomic athletic programs or genomic sports

466  medicine programs are not yet available, a few preliminary suggestions may be articulated here.

467  First, the goals and purposes of the integration of PGx into any sports medicine or athletic

468  program must be clearly defined. Identifying the distinct motivations for and interests in PGx in

15                                                                                    15

469 any sports system (such as the individual athletes seeking empowerment through more

470 personalized pre- and re-habilitation strategies, the coaching personnel seeking information with

471 which to consider talent and injury risks when distributing limited athletic scholarships, and the

472 trainers and medical personnel seeking improved care strategies) is key to preparing the system

473 to avoid unintended consequences and facilitate achievement of its intended purposes. Any

474 integration at the collegiate level will have downstream effects if/when athletes attempt to

475 transition to the professional sports level. Care must be exercised to avoid disparate treatment

476 and impacts that could exacerbate existing inequities (including racial disparities). Second,

477 transparency of the authorized flow of information is integral to a successful program. The extent

478 to which PGx information is accessible and/or shared within the personnel structure of a program

479 affects student-athletes' rights and interests. Prior to any implementation of PGx in sports

480 medicine and athletic programs, designers must make deliberate decisions about the intended

481 direction and volume of the informational flow for the system. Transparency promotes not only

482 compliance with HIPAA/HITECH data security and privacy requirements but also respect for

483 contextual integrity. Third, "terms of use" must be established for all potential decision-makers

484 in the program. Distinct categories of use should be clearly articulated, such as (1) required, (2)

485 recommended, (3) authorized/permissive, and (4) prohibited uses. Terms of use should reflect

486 specific roles of trainers, coaches, and administrators within such programs and also specific

487 contexts in which PGx information might be valuable. Enforcement mechanisms should be

488 articulated. These enforcement mechanisms could incorporate disciplinary standards (such as

489 loss of authorization/access) and could incorporate provisions for liquidated damages for the

490 individual victims of the violations (carefully structured such that any payout avoids jeopardizing

491 the athlete's "amateur" status).  Fourth, such programs should adopt policies and procedures to

492 minimize opportunities for the voluntariness of a decision to participate to become compromised.

493 The existence of coercive pressures alone (from peers, parents, coaches, etc) does not preclude

494 voluntary participation in a PGx sports medicine or athletic program; however, such pressures do

495 present challenges for obtaining voluntary assent/consent. Education of athletes, trainers,

496 coaches, administrators, and media relations for each program could alleviate challenges by

497 establishing reasonable expectations and behavioral norms. Finally, program administrators

498 should engage players' associations and advocates for student-athletes. Each stage (design,

499 implementation, and operations) of programs that integrate PGx would benefit from periodic

16                                                                                                    16

500  review by advocates for the athletes and from regular feedback from players' associations

501  regarding issues emerging with athletes' transition to the professional sports level.

502      While promoting player safety is a laudable goal, facilitating unfettered genetic

503  discrimination of asymptomatic athletes is an unfortunate but likely outcome under present

504  policy conditions. Given disparate rates of participation of individuals of racial minorities in

505  particular mainstream sports (e.g. basketball, football, baseball, soccer, etc), there is a valuable

506  opportunity to provide access to education and genetic risk information (about sudden cardiac

507  death and other serious medical conditions) to individuals and their families (and by extension

508  their communities). This opportunity also suggests there is ample room for disparate

509  discriminatory impacts if decisions based on that screening information (e.g. disqualification

510  from participation) are mandated in fact or in practice. Moreover, the adoption of "fair

511  competition" policies is precisely to restrict normal variation in athletic abilities. The

512  co-existence of the Olympic Games, Paralympics, and Special Olympic Games is an obvious

513  example, though sex segregation, age levels, and weight classes are demonstrative as well.

514  Policies to disqualify, limit, or otherwise classify athletes on the basis of carrying a genetic risk

515  variant is essentially the beginning of genetic segregation in sports. Such policies – even when

516  attempting to serve public health goals –reify public notions of genetic determinism. Moreover,

517  because the distribution of genetic diversity today is a function of our demographic and

518  evolutionary past, such policies could disproportionately distribute risks and benefits of the

519  integration of PGx in sports.

520      Finally, the integration of PGx in sports must be considered as part of a broader data-rich

521  movement. The "Information Age" has enabled increasingly personalized diet and exercise

522   regimes, shaped by personal data generated on mobile devices that monitor nutritional intake,

523  activity levels, and sleep patterns and subsequently shared online with family, friends,

524  teammates, and strangers. While serious athletes are likely early-adopters of PGx (as high

525  rewards may be gained from small improvements in performance), casual athletes may be quick

526  to follow. The public's reception of PGx in sports medicine and athletic programs will be

527  dependent upon genetic literacy and will be influenced (positively or negatively) by the

528  program's design (e.g. the care with which biopsychosocial, legal, and ethical challenges are

529  anticipated and successfully managed). Waiting to educate individuals about genetic information

530  until they are in a clinic as patients (or parents of patients), in a laboratory as research

17                                                                                    17

531 participants, or in an attorney's office or administrative setting facing specific, life-altering

532 decisions (from end-of-life care in light of APOE4 Alzheimer disease risks to participation in

533 competitive sports in light of sudden cardiac arrest risks) is simply too late. Genomic sports

534 medicine and PGx in athletic settings provide an extraordinary opportunity to improve awareness

535 of sudden cardiac death and improve genetic literacy generally. The Ad Council has provided

536 important and effective public service announcements for generations (e.g. the Smokey the Bear

537 campaign in 1944 helping kids prevent forest fires; "A mind is a terrible thing to waste"

538 campaign supporting the United Negro College Fund in 1972; McGruff the Crime Dog taking a

539 bite out of crime in 1978; and the Crash-Test dummies encouraging kids to buckle safety-belts in

540 1985) (Ad Council 2013a). In 2005 the Ad Council launched a Coalition for Healthy Children to

541 fight childhood obesity using campaigns geared toward kids and parents, including "Be a Player:

542 Get up and Play an Hour a Day" and "Eat well. Play hard. Make it balance" campaigns (Ad

543 Council 2013b). Similarly, numerous league-affiliated initiatives (e.g. NFL's "Play 60" or "NBA

544 Cares") are designed to "give back" to communities and improve health, fitness, and quality of

545 life of kids. Pilot campaigns and empiric data are needed to explore whether great strides could

546 be made in improving genetic literacy via exposure to the topic via the public's enthusiastic

547 interest in sports. Whether access to PGx information will empower athletes or oppress them is

548 not a predetermined outcome. To enable the former and prevent the latter requires active policy

549 development rather than passive observation.

550

# Table 1<sub>(on next page)</sub>

AAP and ACMG positions on genetic testing and screening of youth

**Table . AAP and ACMG positions on genetic testing and screening of youth**

| School-based screening or testing | "The AAP and the ACMG do not support school-based genetic screening or testing because the school setting raises concerns about whether the uptake is informed and voluntary, whether privacy and confidentiality are maintained, and whether appropriate genetic counseling is provided before and after testing." (p. 237) |
|---|---|
| Carrier screening | "The AAP and ACMG do not support routine carrier testing or screening for recessive conditions when carrier status has no medical relevance during minority." (p. 236) |
| Direct-to-Consumer testing | "The AAP and the ACMG strongly discourage the use of DTC and home-kit genetic testing of children." (p. 241) |

AAP and ACMG positions on youth access to testing and results

**Table 2. AAP and ACMG positions on youth access to testing and results**

| | |
|---|---|
| Access to testing | "If an adolescent is not interested in testing, and the clinical benefits of knowing will not be relevant for years to decades, the adolescent's dissent should be final." (p.238) |
| | "In the case of predictive testing for childhood-onset conditions or conditions for which childhood interventions will ameliorate future harm…parental authority to determine medical treatment supersedes the minor's preferences with regard to liberty and privacy." (p.238) |
| | "Health-care providers should be cautious about providing such [predictive genetic] testing to minors without the collaboration of their parents." (p. 238) |
| Timing of testing | "Significant deference should be extended to parents regarding the timing of predictive genetic testing for childhood-onset conditions." (p. 238) |
| | "The AAP and the ACMG continue to support the traditional professional recommendation to defer genetic testing for late-onset conditions until adulthood…" (p.238) |
| Access to results | "The AAP and the ACMG believe that a request for the results of a genetic test by a mature adolescent should be given priority over his or her parents' requests to conceal the information." (p. 238) |

Subset of Genes on the ACMG's Minimum List for Reporting

**Table 3.  Subset of Genes on the ACMG's Minimum List for Reporting**

| | |
|---|---|
| Hypertrophic Cardiomyopathy | *MYBPC3, MYH7, TNNT2, TNNI3, TPM1, MYL3, ACTC1, PRKAG2* |
| Long QT Syndrome | *KCNQ1, KCNH2, SCN5A* |
| Marfan Syndrome and related disorders | *FBN1, TGFBR1, TGFBR2, SMAD3, ACTA2, MYLK, MYH11* |

State Survey of Legislative Activity to Prevent SCD of athletes

Westlaw Next was used on June 19, 2013 to search for proposed and enacted legislation in the US related to sudden cardiac death prevention and athletic activity. The search was limited to the last 12 months of activity. The precise search terms used may have failed to uncover all of the legislative activity. OpenStates.org was used to verify the relevant subject matter contained in the bills located using Westlaw Next. Results specific to placement of automatic external defibrillators were not reported in this table. See also "Sudden Cardiac Arrest Legislation by State." Available at http://www.simonsfund.org/sudden-cardiac-arrest-legislation-by-state/ Last accessed June 19, 2013.

Excerpts of the Bethesda Conference #36 Guidelines

**Table 5  Excerpts of the Bethesda Conference #36 Guidelines**

| | |
|---|---|
| HCM | "1. Athletes with a probable or unequivocal clinical diagnosis of HCM *should be excluded from most competitive sports,* with the possible exception of those of low intensity (class IA). This recommendation is independent of age, gender, and phenotypic appearance, and *does not differ for those athletes with or without symptoms,* LV outflow obstruction, or prior treatment with drugs or major interventions with surgery, alcohol septal ablation, pacemaker, or implantable defibrillator." (p. 1341, emphasis added)<br><br>"2. Although the clinical significance and natural history of genotype positive-phenotype negative individuals remains unresolved, no compelling data are available at present with which to preclude these patients from competitive sports, particularly in the absence of cardiac symptoms or a family history of sudden death." (p. 1341) |
| LQTS | "2. Asymptomatic patients with baseline QT prolongation (QTc of 470 ms or more in males, 480 ms or more in females) should be restricted to class IA sports. The restriction limiting participation to class IA activities may be liberalized for the asymptomatic patient with genetically proven type 3 LQTS (LQT3)." (p.1362)<br><br>"3. Patients with genotype-positive/phenotype-negative LQTS (i.e., identification of a LQTS-associated mutation in an asymptomatic individual with a nondiagnostic QTc) may be allowed to participate in competitive sports. Although the risk of sudden cardiac death is not zero in such individuals, there is no compelling data available to justify precluding these individuals (who are being identified with increasing frequency) from competitive activities. Because of the strong association between swimming and LQT1, *persons with genotype positive/phenotype-negative LQT1 should refrain from competitive swimming.*" (p. 1362, emphasis added) |
| MFS and related conditions | "1. Athletes with Marfan syndrome can participate in low and moderate static/low dynamic competitive sports (classes IA and IIA) if they do not have one or more of the following:<br>a. aortic root dilatation …<br>b. moderate-to-severe mitral regurgitation<br>c. family history of dissection or sudden death in a Marfan relative…" (p. 1342)<br><br>"3. *Athletes with Marfan syndrome,* familial aortic aneurysm or dissection, or congenital bicuspid aortic valve with any degree of ascending aortic enlargement… also *should not participate in sports that involve the potential for bodily collision."* (p. 1342, emphasis added)<br><br>1. Athletes with mild or moderate AR [aortic regurgitation], but with LV end-diastolic size that is normal or only mildly increased, consistent with that which may result solely from athletic training, can participate in all competitive sports. … Those with asymptomatic nonsustained ventricular tachycardia at rest or with exertion should participate in low-intensity competitive sports only (class IA)…" (p. 1337) |

Summary of Genes Analyzed by Four DTC sports-related tests in 2011

Direct participant observation occurred in May 2011. The author purchased the four tests from US-based companies identified previously (Wagner and Royal 2012) and submitted her own DNA for analysis. Data on the following variables of interest were collected as part of the participant observation: the purchase process (e.g. informed consent requirements, details regarding terms of service and privacy policies); the DNA collection process (appearance of packaging; educational or marketing literature included; type of specimen required; supplies and instructions); timing issues (estimated wait times; lag times between dates of purchase, kit receipt, DNA sample arrival at company, and results receipt); and issues related to representation and return of results (e.g. media format used; type of information reported; manner in which risk scores or performance predictions were represented; descriptions of methods; readability of results material; and availability of interpretation support). Notably, the motivations, reactions, perceptions of satisfaction, comprehension of results, and other interesting facets of the consumer experience were not the focus of that study: rather, the research was conducted to permit a data-driven discussion of DTC sports-related genetic testing aspects that occur after customers click "purchase." The information reported in Table 6 is a summary of those specific tests as provided in May 2011 using the author's DNA. Tests may have changed. For example, as of late 2012, Athleticode was no longer offering this particular test.
