ABSTRACT

Osteosarcoma (OS) is a primary malignant tumor of bone occurring in young adults. OS stem cells (OSCs) play an important role in the occurrence, growth, metastasis, drug resistance and recurrence of OS. CD133 is an integral membrane glycoprotein, which has been identified as an OSC marker. However, the mechanisms of metastasis, chemoresistance, and progression in CD133(+) OSCs need to be further explored. In this study, we aim to explore differences in miRNA levels between CD133(+) and CD133(−) cells from the MG-63 cell line. We found 20 differentially expressed miRNAs (DEmiRNAs) (16 upregulated and 4 downregulated) in CD133(+) cells compared with CD133(−) cells. Hsa-miR-4485-3p, hsa-miR-4284 and hsa-miR-3656 were the top three upregulated DEmiRNAs, while hsa-miR-487b-3p, hsa-miR-493-5p and hsa-miR-431-5p were the top three downregulated DEmiRNAs. In addition, RT-PCR analysis confirmed that the expression levels of hsa-miR-4284, hsa-miR-4485-3p and hsa-miR-3656 were significantly increased, while the expression levels of hsa-miR-487b-3p, hsa-miR-493-5p, and hsa-miR-431-5p were significantly decreased in CD133(+) cells compared with CD133(−) cells. Moreover, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis revealed that predicted or validated target genes for all 20 DEmiRNAs or the selected 6 DEmiRNAs participated in the “PI3K-Akt signaling pathway,” “Wnt signaling pathway,” “Rap1 signaling pathway,” “Cell cycle” and “MAPK signaling pathway”. Among the selected six DEmiRNAs, miR-4284 was especially interesting. MiR-4284 knockdown significantly reduced the sphere forming capacity of CD133(+) OS cells. The number of invasive CD133(+) OS cells was markedly decreased after miR-4284 knockdown. In addition, miR-4284 knockdown increased the p-β-catenin levels in CD133(+) OS cells. In conclusion, RNA-seq analysis revealed DEmiRNAs between CD133(+) and CD133(−) cells. MiRNAs might play significant roles in the function of OSCs and could serve as targets for OS treatment. MiR-4284 prompted the

INTRODUCTION

Osteosarcoma (OS) is a primary malignant tumor of bone occurring in young adults, with a morbidity of 4,000,000 per year (*Li et al., 2016; Yin et al., 2021*). A combination of surgery with adjuvant and neoadjuvant chemotherapy has been developed to improve the 5-year survival rate of OS patients; nevertheless, the prognosis of OS patients remains poor due to the high rates of tumor metastasis and recurrence, and drug resistance (*Liu et al., 2021; Ren et al., 2021; Yu et al., 2021; Zhang, Ma & Li, 2019a*). Therefore, the molecular mechanisms underlying metastasis, chemoresistance, and progression of OS need to be clarified to improve therapeutic options.

Cancer stem cells (CSCs) are a subpopulation of tumor cells with capacities of self-renewal, differentiation, and pluripotent differentiation (*Lin et al., 2021; Zhang, Ma & Li, 2019a*). CSCs cause disease recurrence and chemoresistance, and lead to tumor relapse and metastasis (*Camuzard et al., 2020; Tornin et al., 2021; Zhang et al., 2019b*). Recently, OS stem cells (OSCs) have been shown to cause recurrence and metastasis (*Wang et al., 2020a*). CD133 is considered as a stem cell marker for normal and cancerous tissues (*Li et al., 2013*). CD133 is also identified as a CSC marker in OS (*Ni et al., 2015*). However, the mechanisms underlying the link between recurrence and metastasis of OS and CD133 expression in OS cells need to be further explored.

MiRNAs have been shown to regulate genes associated with the transformation, growth, apoptosis, tumorigenic ability and self-renewal capacity of OSCs (*Chang et al., 2015; Yao et al., 2020; Zhang et al., 2020; Zhao et al., 2017; Zou et al., 2017*). In the present study, we explore the differentially expressed miRNAs (DEmiRNAs) between CD133(+) and CD133(-) MG-63 cells, with the aim to identify possible targets for novel OS treatment strategies.

MATERIALS AND METHODS

Cell culture

MG-63 and Saos-2 cells were provided by the China Center for Type Culture Collection as in our previous study (*Shu et al., 2020*). MG-63 and Saos-2 cells were cultured in RPMI-1640 and McCoy's 5A medium (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA), respectively, supplemented with 10% FBS (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA), 1% L-glutamine, and 1% penicillin-streptomycin sulfate (Thermo Fisher Scientific, Inc., Waltham, MA, USA) at 37 °C in a 5% CO₂ humidity-controlled incubator (*Chen et al., 2019; Zhou et al., 2016*).

Fluorescence-activated cell sorting

MG-63 and Saos-2 cell suspensions were prepared by trypsinization, and 1×10^6 cells in 500 μ l were stained with phycoerythrin-labeled anti-CD133 (1:50, Miltenyi Biotec GmbH,

Bergisch Gladbach, Germany) at 4 °C for 60 min. After washing, the CD133(+) and CD133 (-) MG-63 cells were sorted by fluorescence-activated cell sorting (FACS) using a BD FACS AriaIII system (BD Biosciences).

RNA extraction and miRNA array

Total RNA was extracted from MG-63 cells using TRIzol reagent (Takara, Japan) and the miRNeasy mini kit (Qiagen, West Sussex, United Kingdom) following the manufacturer's instructions. The extracted RNAs were labeled based on the miRCURY™ Hy3™/Hy™ Power labeling kit (Exiqon, Vedbaek, Denmark) and hybridized on a miRCURY™ LNA Array (version 18.0, Exiqon, Vedbaek, Denmark). After washing, the slides were scanned using an Axon GenePix 4000B microarray scanner (Axon Instruments, Foster City, CA, USA). The scanned images were imported into the GenePix Pro 6.0 platform (Axon Instruments) for grid alignments and analysis. Replicated miRNAs were averaged, and miRNAs with expression intensities of ≥ 50 in all of the samples were used to calculate the normalized expression using the median normalization method. The DE miRNAs were identified by volcano plot filtering. Finally, hierarchical clustering was performed to identify DE miRNAs using MEV software (Version 4.6; TIGR, Microarray Software Suite 4, Boston, MA, USA).

Prediction of target genes of DE miRNAs and collection of validated target genes

DE miRNA-mRNA interactions were predicted using TargetScan (<http://www.targetscan.org/>), miRwalk (<http://www.ma.uni-heidelberg.de/apps/zmf/mirwalk/>), and the miRDB (<http://www.mirdb.org/>) database. The validated DE miRNA-mRNA interactions were collected from miRTarBase (<https://mirtarbase.cuhk.edu.cn/>).

GO and KEGG pathway enrichment analyses of target genes of DE miRNAs

Target genes of DE miRNAs were obtained, and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis and Gene Ontology (GO) analysis were performed using DAVID (*Guo et al., 2019*). The cut-off criterion for both analyses was $P < 0.05$.

Construction of miRNA-mRNA pathway network

The association among the differently expressed miRNAs, mRNAs and the mRNA miRNAs, mRNAs and pathways in the network were represented by nodes of different shapes and colors.

qRT-PCR

Total RNA was extracted using TRIzol reagent (Takara, Japan). Complementary DNA (cDNA) was then synthesized through reverse transcription of the RNA using the Prime-Script RT reagent Kit and gDNA Eraser (TaKaRa) (*Wang et al., 2020a*). Subsequently, quantitative real-time PCR (qRT-PCR) was performed using the SYBR Premix Ex Taq II Kit (Takara, Kusatsu, Japan) and an ABI 7500 qRT-PCR system (Applied

Biosystems, Waltham, MA, USA), using the DNA as template. *U6* was used as the internal control. The relative miRNA expression levels were calculated based on the $2^{-\Delta\Delta Ct}$ equation. The primers (Sangon Biotech, Shanghai, China) are shown in [Table 1](#).

Sphere formation assay

MG-63 and Saos-2 cells (500 cells/well) were plated in Ultra-Low Attachment 24-well plates (Corning, Inc., Corning, NY, USA) with 0.8% methyl cellulose (Sigma-Aldrich, St. Louis, MO, USA; Merck KGaA, Darmstadt, Germany) supplemented with 20 μ l/ml B27, 20 ng/ml bFGF, 10 ng/ml epidermal growth factor, 1% L-glutamine and 1% penicillin-streptomycin sulfate (all were obtained from Thermo Fisher Scientific, Inc., Waltham, MA, USA). Every 3 days, each well was examined under a light microscope (IX71; Olympus Corporation, Tokyo, Japan).

Invasion assay

To assess the invasive ability, 2×10^5 serum-starved cells were seeded in 200 μ l medium without serum and then plated in the top of a Transwell™ chamber (24-well insert; pore size, 8 μ m; Corning, Corning, NY, USA) that was coated with diluted Matrigel (BD Biosciences). After 8 h, the infiltrating cells were stained with 4,6-diamidino-2-phenylindole (DAPI) and counted using a microscope. The invasive ability of cells was quantified.

MiR-4284 knockdown

FACS-sorted CD133(+) and CD133(-) cells were seeded into 6-well plates and incubated overnight. They were transfected with siRNA against miR-4284 or negative control (Ribobio Co) at 60 nM using Lipofectamine 2000 (Invitrogen) according to the manufacturer's instructions. After 72 h, the cells were harvested and RNA and protein were isolated.

Western blot

Proteins were isolated using a Total Protein Extraction Kit (Thermo Fisher Scientific) according to the manufacturer's protocol. The following primary antibodies were used to detect protein expression: anti- β -catenin (#8480; Cell Signaling), anti-phospho- β -catenin (#9561; Cell Signaling), and anti- β -actin (#4970; Cell Signaling). Antibodies were diluted as specified in the specifications.

Statistical analysis

Data were analyzed using GraphPad Prism 8 (GraphPad Software, Inc., San Diego, CA, USA). Continuous data are expressed as mean \pm SD. Differences between groups were analyzed using the two-tailed Student unpaired *t*-test. Results were considered statistically significant if $P < 0.05$.

RESULTS

DE miRNAs between CD133(+) and CD133(-) MG-63 cells

FACS-sorted CD133(+) and CD133(-) MG-63 cells (Fig. 1A) were grown under serum-free conditions for the miRNA array. DE miRNAs between CD133(+) and CD133(-) MG-63 cells were identified. In total, 20 DE miRNAs (fold change ≥ 1.2 , $P < 0.05$) were found (16 upregulated in CD133(+) cells and 4 downregulated). Hierarchical clustering

graphs and volcano plots of the 20 DEmiRNAs between CD133(+) and CD133(-) MG-63 cells are shown in [Figs. 1B](#) and [1C](#). The DEmiRNAs are listed in [Table 2](#).

Functional enrichment analysis of DEmiRNA target genes

In total, 9,687 predicted target genes of the 20 DEmiRNAs were obtained. Of these predicted target genes, experimental evidence reported in the literature was obtained for 2,099 validated target genes.

To obtain a deeper understanding of the roles of the 20 DEmiRNAs, GO enrichment analysis and KEGG pathway analysis were performed on predicted and validated target genes. GO analysis indicated that among the predicted target genes, several biological processes, including “regulation of cell morphogenesis” and “cell junction organization” ($P < 0.05$), were significantly enriched ([Fig. 2A](#)). KEGG pathway enrichment analysis indicated that among the predicted target genes, several KEGG pathways were significantly enriched ($P < 0.05$), including “Wnt signaling pathway,” “MAPK signaling pathway,” “PI3K-Akt signaling pathway,” and “Ras signaling pathway” ([Fig. 2B](#)).

GO analysis indicated that among the validated target genes, several biological processes, including “chromatin assembly” and “regulation of protein stability” ($P < 0.05$), were significantly enriched ([Fig. 3A](#)). KEGG pathway enrichment analysis indicated that among the validated target genes, several pathways were statistically enriched

($P < 0.05$), including “Cell cycle,” “Fc epsilon RI signaling pathway,” “ErbB signaling pathway,” and “Rap1 signaling pathway” (Fig. 3B).

Validation and functional exploration of the top three upregulated miRNAs and top 3 downregulated miRNAs

The expression of the top three upregulated miRNAs and top three downregulated miRNAs was further validated *via* RT-PCR. The results confirmed that the expression levels of hsa-miR-4284, hsa-miR-4485-3p, and hsa-miR-3656 were significantly increased in CD133(+) cells compared with CD133(-) cells (Figs. 4A–4C), while the expression levels of hsa-miR-487b-3p, hsa-miR-493-5p, and hsa-miR-431-5p were significantly decreased in CD133(+) cells compared with CD133(-) cells (Figs. 4B–4F).

After validation by RT-PCR, GO analysis and KEGG pathway enrichment analysis of the predicted and validated target genes of the top three upregulated miRNAs and top three downregulated miRNAs were also performed (Figs. 5 and 6). GO analysis indicated that among the predicted target genes, several biological, including biological processes

such as “Wnt signaling pathway,” “calcium modulating pathway,” “transcription from RNA polymerase II promoter,” and “positive regulation of GTPase activity” ($P < 0.05$), were significantly enriched (Fig. 5A). KEGG pathway enrichment analysis indicated that among the predicted target genes, several KEGG pathways were significantly enriched ($P < 0.05$), including “Wnt signaling pathway,” “MAPK signaling pathway,” “Rap1 signaling pathway,” “PI3K-Akt signaling pathway,” “cGMP-PKG signaling pathway,” and “Ras signaling pathway” (Fig. 5B). GO analysis indicated that among the validated target genes, several biological processes, including “cell cycle,” “stem cell population maintenance,” and “mesenchymal cell differentiation” ($P < 0.05$), were significantly enriched (Fig. 6A). KEGG pathway enrichment analysis indicated that among the validated target genes, several pathways were statistically enriched ($P < 0.05$), including “p53 signaling pathway” and “PPAR signaling pathway” (Fig. 6B). The results of the functional enrichment analysis of these six confirmed that DE miRNA target genes are in

agreement with the functional enrichment analysis of the total number of DE miRNA target genes.

We observed a significant interconnection between the molecular roles and signaling pathways of predicted and validated target mRNAs (Tables S1 and S2). For instance, in the interconnection among predicted target mRNAs and multiple signaling pathways, WNT7A and FZD5 regulates “Wnt signaling pathway,” “Proteoglycans in cancer,” and “Pathways in cancer”. IGF1R regulates “Proteoglycans in cancer,” “PI3K-Akt signaling pathway,” “Pathways in cancer,” “Ras signaling pathway,” “Rap1 signaling pathway,” and “Transcriptional misregulation in cancer”. AKT3 regulates “PI3K-Akt signaling pathway,” “Ras signaling pathway,” “Pathways in cancer,” “Rap1 signaling pathway,” “cGMP-PKG signaling pathway,” “Proteoglycans in cancer,” and “MAPK signaling pathway”. IGF1R is the predicted target gene for miR-493-5p and miR-431-5p. AKT3 is the predicted target gene of hsa-miR-493-5p. In the interconnection among validated target mRNAs and multiple signaling pathways, CDKN1A and CDK4 regulate the p53 signaling pathway. WNT7A and FZD5 are predicted target genes of hsa-miR-4284. CDKN1A is a validated target gene for hsa-miR-493-5p. CDK4 is a validated target gene for hsa-miR-431-5p and hsa-miR-4284.

MiR-4284 regulates the self-renewal capacity and invasion ability in CD133(+) cells through Wnt signaling

To evaluate the effect of miR-4284 on the cells’ self-renewal ability, we initially performed a sphere formation assay of CD133(+) and CD133(–) cells transfected with siRNA targeting miR-4284. MiR-4284 knockdown significantly reduced the sphere forming capacity of CD133(+) from MG-63 and Saos-2 cells (Fig. 7A). Next, we investigated the role of miR-4284 in the regulation of the invasion ability of OSCs. After 48 h, the number of invading cells in each group was calculated. The results showed that the number of invasive CD133(+) MG-63 and Saos-2 cells was markedly decreased after miR-4284 knockdown (Fig. 7B).

Next, we investigated the relationship between miR-4284 and β -catenin phosphorylation. As shown in Fig. 7C, the level of phospho- β -catenin was upregulated, while the expression level of total β -catenin remained unaltered. Collectively, these data demonstrate that miR-4284 may promote the self-renewal ability and invasion of OSCs through Wnt signaling.

DISCUSSION

OS, the most common primary bone tumor, principally arises in the long bones of children and young adults. However, the molecular mechanisms underlying the development of OS are not well clarified. Revealing these processes may uncover novel targets for the prevention and treatment of OS.

MiRNAs have been shown to regulate genes associated with tumor growth and progression of OS (Dai et al., 2021; Gong, Wei & Liu, 2021; Wang et al., 2020b). For example, decreased miR-1274a levels have been associated with tumor suppression in OS (Feng et al., 2021). Upregulation of miR-128-3p improved resistance to cisplatin in

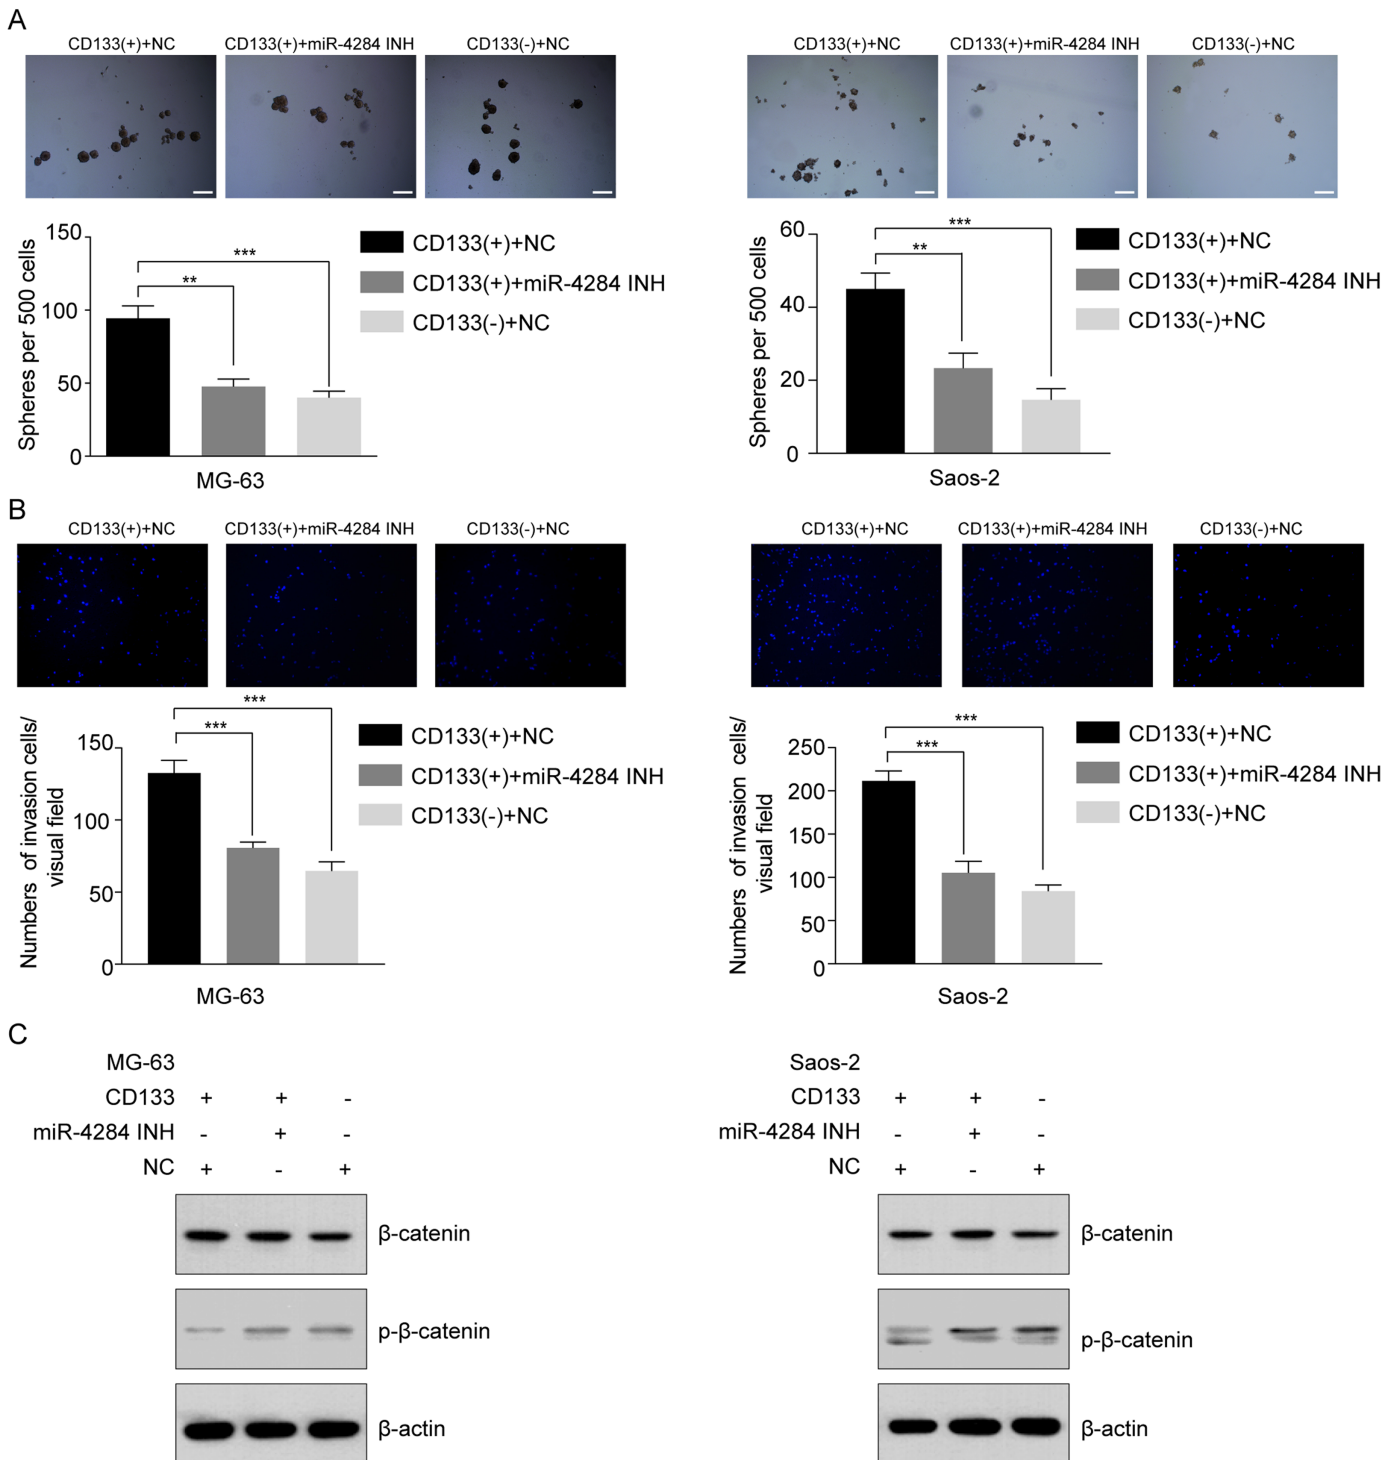

Figure 7 Relationship between miR-4284 and the self-renewal and invasion ability and Wnt pathway in CD133(+) cells from MG-63 and Saos-2 cells. (A) Sphere formation in CD133(+), CD133(-) cells transfected with negative control and CD133(+) cells transfected with miR-4284 inhibitor in MG-63 and Saos-2 cells were identified in a low attachment plate with serum-free media. (B) The invasion ability in CD133(+), CD133(-) cells transfected with negative control and CD133(+) cells transfected with miR-4284 inhibitor in MG-63 and Saos-2 cells were identified using Matrigel-coated invasion assay. [Full-size !\[\]\(5f471a71b78d7676bc356df190b88ab4_img.jpg\) DOI: 10.7717/peerj.12115/fig-7](https://doi.org/10.7717/peerj.12115/fig-7)

143B and MG-63 cell lines and miR-128-3p might function as an oncogene in OS (Zhu *et al.*, 2021). CSCs are considered as the main cause of metastasis and recurrence (Wang *et al.*, 2020a). Moreover, miRNAs have been shown to be involved in the transformation, growth, apoptosis, invasion, self-renewal capacity and tumorigenic ability of OSCs (Chang *et al.*, 2015; Yao *et al.*, 2020; Zhang *et al.*, 2020; Zhao *et al.*, 2017; Zou *et al.*, 2017). In OSCs, the TGF β -miR-499a-SHKBP1 axis orchestrates the epithelial-mesenchymal transition (EMT)-associated kinase switch which contributes to resistance to EGFR inhibitors (Wang *et al.*, 2019). Altered miR-19a levels play key roles in OSCs, partly *via* targeting the phosphatase and tensin homolog deleted on chromosome 10 (PTEN) (Zhao *et al.*, 2017). MiR-34a may inhibit OS metastasis and growth by decreasing the cells' self-renewal and invasive capacities, as it eliminates the tumorigenic ability of OS *in vitro* (Zou *et al.*, 2017). These studies suggest the important roles of miRNAs in OSCs and OS.

CD133, CD26, ALDH1, CD117 and Stro-1 have been reported as the OSC markers (Adhikari *et al.*, 2010; Bao, Cheng & Chai, 2018; Czarnecka *et al.*, 2020; Ni *et al.*, 2015; Saini *et al.*, 2012). CD133(+) OS cells exhibit stem-like gene expression, act as tumorinitiating cells, and play a role in the development of drug resistance and metastasis (Czarnecka *et al.*, 2020). Lower CD24 and CD44 expression was observed in spheres as compared with monolayers in CHA59, Saos-2 and HuO9 OS cells and a significant decrease in CD24 and CD44 expression accompanied sphere culture (Saini *et al.*, 2012). Yao *et al.* (2020) found a positive correlation between high expression levels of miR-155 and upregulation of CSC surface markers (CD133 and CD24) in U2OS cells. Aldehyde dehydrogenase 1 (ALDH1) is another commonly used biomarker of CSCs in a variety of human cancers, including OS (Bao, Cheng & Chai, 2018; Ni *et al.*, 2015). The activation of ALDH1+CD133+ cells in OS is accompanied by the downregulation of miR-143 expression (Zhou *et al.*, 2015). CD117 and Stro-1 can be used to identify OSCs associated with the most lethal characteristics of the disease—metastasis and drug resistance—and these markers are promising candidate targets for OSC-targeted drug delivery (Adhikari *et al.*, 2010). MiRNAs are differentially expressed CD117+stro-1+ and CD117-stro-1- OS cells, and miR-15a, miR-302a, miR-423-5p, miR-212, miR-1247, miR-518b, miR-890, and miR-1243 are DE miRNAs (Zhao *et al.*, 2015). The exact roles of these markers in OSCs still need to be further studied.

In the present study, we uncovered 20 DE miRNAs between CD133(+) and CD133(-) MG-63 cells (16 upregulated in CD133(+) cells and 4 downregulated). Hsa-miR-4485-3p, hsa-miR-4284, and hsa-miR-3656 were the top three upregulated DE miRNAs, while hsa-miR-487b-3p, hsa-miR-493-5p and hsa-miR-431-5p were the top three downregulated DE miRNAs. The significantly differential expression of these six DE miRNAs was confirmed by RT-PCR analysis. In a previous study, upregulation of miR-487b-3p inhibited OS formation and the combination treatment of doxorubicin and miR-487b-3p significantly inhibited CSC-induced tumor growth (Cheng *et al.*, 2020). The level of circulating miR-493-5p is a novel potential diagnostic biomarker for OS (Huang *et al.*, 2019). Overexpression of miR-493-5p inhibits metastasis and proliferation of OS cells by inactivating the PI3K/AKT signaling pathway and downregulating KLF5

(Zhang *et al.*, 2019b). Upregulation of miR-431-5p inhibits OS the tumorigenesis *via* targeting PANX3 (Sun *et al.*, 2020). The roles of these six DE miRNAs in OS and OSCs still require further exploration.

Furthermore, we found that predicted target genes of the 20 identified DE miRNAs were enriched in several biological processes, including “regulation of cell morphogenesis” and “cell junction organization.” KEGG analysis of the predicted target genes of the 20 identified DE miRNAs revealed several significantly enriched pathways, including the “Wnt signaling pathway,” “Ras signaling pathway,” “PI3K-Akt signaling pathway,” and “MAPK signaling pathway.” Among the validated target genes, several biological processes, including “regulation of protein stability” and “chromatin assembly,” were significantly enriched. KEGG pathway enrichment analysis of the validated target genes revealed several significantly enriched pathways, including “Cell cycle,” “Rap1 signaling pathway,” “Fc epsilon RI signaling pathway,” and “ErbB signaling pathway.”

Of the top three upregulated miRNAs and top three downregulated miRNAs, miR-4284 was particularly interesting. A recent study found that miR-4284 could promote gastric tumor cell growth, migration and invasion by directly targeting TET1 (Li *et al.*, 2018). In addition, miR-4284 was shown to promote the development of diffuse large B-cell lymphoma (Tamaddon *et al.*, 2016). The expression of miR-4284 was also increased in clinical samples and cell lines of non-small cell lung cancer (NSCLC), and knockdown of miR-4284 inhibited the proliferation, migration and invasion of tumor cells (Tian, Wang & Du, 2021). These studies suggest that miR-4284 promotes the development of gastric cancer, diffuse large B-cell lymphoma, and NSCLC. In the present study, we found that miR-4284 expression was higher in CD133(+) than in CD133(-) cells from MG-63 cells. We further found that miR-4284 knockdown significantly reduced the sphere forming capacity of CD133(+) OS cells and the number of invasive CD133(+) OS cells markedly decreased after miR-4284 knockdown. Our present results suggest that miR-4284 prompts the self-renewal and increases the invasive ability of OSCs.

The Wnt signaling pathway plays important roles in the progression and development of many cancers including OS (Liang *et al.*, 2021; Taciak *et al.*, 2018). The Wnt signaling pathway has been reported to be activated in OS (Chen *et al.*, 2015). LncRNA MRPL23-AS1 promotes tumor progression and carcinogenesis in OS by activating Wnt/ β -catenin signaling *via* inhibiting miR-30b and upregulating MYH9 (Zhang *et al.*, 2021). Blocking Wnt/LRP5 signaling modulates the EMT and suppresses the activity of metalloproteinases in OS Saos-2 cells (Guo *et al.*, 2007). It has also been reported that Wnt signaling is only activated in the CSC subpopulation of OS cells (Singla *et al.*, 2020). In the present study, the Wnt signaling pathway was significantly enriched among the predicted target genes of the 20 identified DE miRNAs. β -Catenin is a significant downstream effector of the Wnt signaling pathway (Pinczewski *et al.*, 2021). In a previous study, the endogenous p-LRP6 level was significantly increased after subarachnoid hemorrhage and further augmented after the administration of HLY78, which resulted in activation of the Wnt pathway by inhibition of the phosphorylation of β -catenin, Bax, and cleaved caspase 3 (Luo *et al.*, 2020). Inhibiting β -catenin phosphorylation in glioma stem cells can lead to activation of the Wnt signaling pathway (Zhang *et al.*, 2018). In the

present study, miR-4284 knockdown increased the expression of p- β -catenin in CD133(+) OS cells, suggesting that miR-4284 may inhibit the Wnt signaling pathway by promoting β -catenin phosphorylation in OSCs.

In the present study, the identification of DE miRNAs between CD133(+) and CD133(-) cells from MG-63 cells provided valuable insight regarding the stemness of OS cells. Nowadays, the number of identified miRNAs is growing quickly and hence further studies will be needed to explore their molecular and biological functions in OS. However, there are several limitations to this study. First, we studied the miRNA profile of OSCs. The expression of selected miRNAs in patient samples remains to be studied. Second, the roles of miR-4284 in CD133(+) cells were preliminarily explored, and the functional mechanism of miR-4284 needs to be further studied.

In conclusion, DE miRNAs between CD133(+) and CD133(-) MG-63 cells were identified. MiRNAs might play significant roles in the function of OSCs and serve as potential targets for OS treatment. Moreover, miR-4284 promoted the self-renewal and invasion of OSCs. The function of miR-4284 might be associated with the Wnt signaling pathway.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the National Natural Science Foundation of China (81330043, 81071499), the Beijing Municipal Health Commission (BMHC-2019-9, BMHC-2018-4), the Natural Science Foundation of Beijing JiShuiTan Hospital (ZR-201906), the CAMS Innovation Fund for Medical Sciences (2017-2M-3-005), and the Independent Issue of State Key Laboratory of Molecular Oncology (SKL-2019-17). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:

National Natural Science Foundation of China: 81330043, 81071499.

Beijing Municipal Health Commission: BMHC-2019-9, BMHC-2018-4.

Natural Science Foundation of Beijing JiShuiTan Hospital: ZR-201906.

CAMS Innovation Fund for Medical Sciences: 2017-2M-3-005.

Independent Issue of State Key Laboratory of Molecular Oncology: SKL-2019-17.

Competing Interests

The authors declare that they have no competing interests.

Author Contributions

- Xiong Shu conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.

- Weifeng Liu analyzed the data, prepared figures and/or tables, and approved the final draft.
- Huiqi Liu conceived and designed the experiments, performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Hui Qi conceived and designed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Chengai Wu conceived and designed the experiments, analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Yu-Liang Ran conceived and designed the experiments, performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
