

Chinese Interpreting Studies: A data-driven analysis of a dynamic field of enquiry

Ziyun Xu, Leonid B Pekelis

Over the five decades since its beginnings, Chinese Interpreting Studies (CIS) has evolved into a dynamic field of academic enquiry with more than 3,500 scholars and 4,200 publications. Using quantitative and qualitative analysis, this scientometric study delves deep into CIS citation data to examine some of the noteworthy trends and patterns of behavior in the field: how can the field's progress be quantified by means of citation analysis? Do its authors tend repeatedly to cite 'classic' papers or are they more drawn to their colleagues' latest research? What different effects does the choice of empirical vs. theoretical research have on the use of citations in the various research brackets? The findings show that the field is steadily moving forward with new papers continuously being cited, although a number of influential papers stand out, having received a stream of citations in all the years examined. CIS scholars also have a tendency to cite much older English than Chinese publications across all document types, and empirical research has the greatest influence on the citation behavior of doctoral scholars, while theoretical studies have the largest impact on that of article authors. The goal of this study is to demonstrate the merits of blending quantitative and qualitative analyses to uncover hidden trends .

Chinese Interpreting Studies

A data-driven analysis of a dynamic field of enquiry

Abstract:

Over the five decades since its beginnings, Chinese Interpreting Studies (CIS) has evolved into a dynamic field of academic enquiry with more than 3,500 scholars and 4,200 publications. Using quantitative and qualitative analysis, this scientometric study delves deep into CIS citation data to examine some of the noteworthy trends and patterns of behavior in the field: how can the field's progress be quantified by means of citation analysis? Do its authors tend repeatedly to cite 'classic' papers or are they more drawn to their colleagues' latest research? What different effects does the choice of empirical vs. theoretical research have on the use of citations in the various research brackets? The findings show that the field is steadily moving forward with new papers continuously being cited, although a number of influential papers stand out, having received a stream of citations in all the years examined. CIS scholars also have a tendency to cite much older English than Chinese publications across all document types, and empirical research has the greatest influence on the citation behavior of doctoral scholars, while theoretical studies have the largest impact on that of article authors. The goal of this study is to demonstrate the merits of blending quantitative and qualitative analyses to uncover hidden trends.

Keywords: scientometrics, Chinese Interpreting Studies, citation analysis, statistical modeling

32 1. Introduction

33

34 There are various channels through which scholars communicate with one another, easing the
35 flow of knowledge and furthering the advance of science. One such important channel comes in
36 the form of citations, which are the result of the duty incumbent upon all scholars to conduct
37 comprehensive and critical reviews of existing literature before embarking on new research, to
38 gain a deep understanding of the field and find the precise empty niche into which their own
39 work will fit, referring to previous related work to bolster their arguments. Though citing other
40 people's work did not become the norm in scientific writing until the early 1900s (Garfield
41 1979), it is now standard and required practice for authors to acknowledge the works of
42 predecessors from which they have drawn inspiration, thereby maintaining the 'intellectual
43 lineage' from one generation of academics to the next. Citation analysis has long attracted
44 attention in the scientific community (see for example Garfield 1972; White & McCain 1998;
45 Baumgartner & Pieters 2003; Vallmitjana & Sabaté 2008). This is mostly as a consequence of
46 Kuhn's 1970 ground-breaking work on the nature of science, in which he called on future
47 scholars to recognize the crucial importance of adopting an empirical approach to studying the
48 structure of the scientific community.

49

50 Such academic pursuits are particularly relevant in the Translation and Interpreting Studies
51 (TIS) community, because it has experienced a significant growth in both quantitative and
52 qualitative terms over the past two decades, and because hundreds of papers with diverse
53 research methodologies and themes are produced on a yearly basis (Franco Aixelá 2013). During
54 this period of significant growth, more empirical studies are needed if we are to fully appreciate
55 the patterns of communication and trends in TIS. A number of earlier scholars have used citation
56 data to trace the evolution of the field and understand how scholars communicate with each other
57 (see for example, Pöchhacker 1995; Gile 2005; Grbić & Pöllabauer 2009). However, despite its
58 usefulness, there are limitations to a purely quantitative approach in analyzing TIS citation data,
59 and qualitative analysis is called for in order to obtain a fuller picture of the discipline (Gile
60 2000). The purpose of this scientometric study is to marry quantitative and qualitative
61 approaches to analyzing citation in order to obtain a panorama of CIS' evolution and reveal its
62 hidden trends and predominant theoretical influences.

63 **2. Background**

64 **2.1 Major Questions**

65
66 CIS has been developing rapidly since the 1990s, as evidenced by its increasing number of
67 publications and researchers (Chen 2009). Using an all-but-exhaustive collection of citation data,
68 three component strands of CIS (journal articles, MA theses, and doctoral dissertations) were
69 studied with the aim of finding changes or differences in patterns of citation. In what ways is the
70 citation network changing? Are authors still primarily influenced by older works or do more
71 recent ones now hold the ascendancy? How do different research methods (theoretical, empirical,
72 etc.) affect the use of citations in the works themselves? The three bodies of literature are
73 generally produced by three distinct groups of authors: established researchers for journal articles
74 and conference proceedings; graduate students for MA theses; and PhD students for doctoral
75 dissertations (Xu 2014 & 2015). Examining these three strands individually is necessary if we
76 are to fully understand how each contributes to advancing the field as a whole.

77

78 **2.2 Literature Review**

79

80 The study of research trends in Translation and Interpreting Studies (TIS) is currently
81 dominated by citation analysis (see for example Gile 2005 & 2006; Gao 2008; Franco Aixelá
82 2004). There are various methods of carrying out citation analysis, but the overall basic concept
83 is always the same. First a sample of articles is selected; the researcher then counts the number of
84 times each article is cited in other works. Citing (or ‘source’) works can be categorized according
85 to type (conference proceedings, monographs, periodicals, etc.), and a weight assigned to each
86 citation based on various factors: the type of publication in which it is being cited; the number of
87 authors being cited; in the case of co-authorships an author’s contribution to the work being cited
88 (the ‘target’); and others. Finally, a numerical score is calculated for each author, article, research
89 institution, journal or whatever the researcher is focusing on; these scores can then be ranked to
90 indicate each cited individual’s or entity’s relative impact (Lowry et al. 2007). The procedure is
91 based on the premise that the number of times a work is cited is a measure of its influence in the
92 academic world.

93

94 Citation analysis has increasingly been adopted to map out the historical evolution of a
95 particular area of study, the impact of individual researchers, academic institutions or scientific
96 publications, the extent of collaboration between these, or the influence of certain disciplines on
97 others (Glänzel 2003; Kalaitzidakis et al. 2003). In their general study of the technique, Braun et
98 al. (1985) found that articles cited between five and ten times each year during the period
99 immediately following their publication tend to be assimilated into the relevant discipline's
100 'universal' stock of knowledge, and that conversely, if articles go uncited over the same period,
101 there is little chance of such assimilation taking place. Citation analysis has been used in well-
102 established disciplines such as linguistics (White 2004), psychology (Carr & Britton 2003; White
103 & White 1977), and information science (White & McCain 1998), but has also been highly
104 useful in assessing research patterns in fields with much shorter histories, such as TIS (Gile
105 2005).

106

107 Given the increasing popularity of citation analysis, Garfield's Institute of Scientific
108 Information (ISI) produced the first citation index¹ for articles published in academic journals
109 shortly after it was founded in 1960. The ISI has since produced numerous other indexes, which
110 have grown to encompass more than 40 million records and 8,700 research journals (Meho 2006)
111 and are now accessible online via Thomson Reuters' Web of Science. Although originally
112 designed to facilitate access to information, the indexes are now widely recognized as an
113 important source of empirical data for scientometric research (Ivancheva 2008).

114

115 Despite the growth in use of citation indexes, the exponential expansion of scientific research
116 into new disciplines over the past four decades has resulted in numerous high-quality journals
117 being excluded from the 'baskets' used by the leading indexes. To facilitate improved
118 communication among researchers in the field of interpreting, in 1990 Daniel Gile set out to
119 create an international network — the Conference Interpreting Research Information Network
120 (CIRIN) — which publishes a biannual Bulletin. Since then several other searchable databases
121 have been created for this discipline: the Bibliography of Interpreting and Translation (BITRA),

¹ A citation index is a database that archives bibliographic information from publications: it allows users to trace the progress of a concept or subject of inquiry by sourcing published works that cite particular authors or articles.

122 for example, carries over 50,000 entries and is updated on a monthly basis, while the Translation
123 Studies Bibliography (TSB) subscription service has 24,500 entries to date.

124

125 Gile (2005) surveyed citations from 47 papers on translator and interpreter training written by
126 Western academics to find out which theories were most influential, the languages that target
127 works were most often written in, and whether empirical or non-empirical research had more
128 influence. The interpreter training material he sampled for the study revealed several interesting
129 points: the model advocated by the Association Internationale des Interprètes de Conférence
130 (AIIC) was the most frequently cited theory, while functional theories were dominant in
131 translator training; the majority of the cited literature was written in English; and empirical
132 research played very little part in the papers sampled. In another study (2006) he introduced a
133 qualitative dimension to his analysis by grouping citations into different categories (concepts,
134 methods, findings, etc.), on the assumption that such an approach would provide a more nuanced
135 analysis of each category's impact on the evolution of Translation and Interpreting Studies (TIS).
136 The study revealed that scholars were cited on their methods and findings in less than 10% of the
137 articles in the corpus. Adopting the same classification scheme, Nasr (2010) examined a corpus
138 of 542 texts on translator training. Her study produced a similar result, indicating that empirical
139 research was not influential in shaping research into that subject either.

140

141 By developing methodologies based on citation analysis, earlier researchers have laid the
142 groundwork for assessing the impact of an individual's work and tracing the evolution of a field.
143 In addition to quantitative analysis, qualitative approaches have been proposed to study how
144 scholars cite one another. However, the application of these methodological techniques to
145 investigating the evolution of CIS has to date been very limited. The goal of the present study
146 was to adopt a blended approach with equal emphasis on both quantitative and qualitative
147 considerations to explore how the CIS citation network changes over time and how different
148 research methodologies have affected citation behaviors.

149

150

151 **3. The Present Study**

152

153 Expanding on the broad themes of enquiry outlined at the beginning of this paper, three more
154 in-depth mini-studies were drawn up to address some of the major issues unresolved by previous
155 researchers. The rationale for each is summarized in the following section.

156

157 **3.1 Data Organization**

158

159 The author created a near-comprehensive database of 59,303 citations from the 1,289 Chinese
160 MA theses, 32 doctoral dissertations and 2,909 research papers available to him. The CIS
161 literature was collected from several sources: field trips to university libraries, interlibrary loans,
162 book purchases, and academic databases such as CNKI, Wanfang and the National Digital
163 Library of Theses and Dissertations in Taiwan. Publications with no bibliographic references
164 were excluded from the analysis. Since these publications were obtained from multiple databases
165 and different institutions, convenience sampling should not be an issue in this study: it would
166 only be a problem if there were some inherent qualities among those one was able to sample that
167 would not be present in the entire population. There is no good reason to believe that the
168 publications found in the present sample would be different from ones found elsewhere. Once
169 collected, the references were manually entered into a relational database which uses Structured
170 Query Language (SQL) for managing data.

171

172 **3.2 Study 1**

173 **3.2.1 Research question**

174

175 Do CIS authors tend repeatedly to cite 'classic' papers, or are they more drawn to the latest
176 research within the field? How can the progress of CIS be quantified by means of citation
177 analysis?

178

179 A number of scholars (Merton, 1967; Lederberg, 1972; Garfield, 1977) have observed that at
180 the same time as science constantly moves forward, there exists a phenomenon known as
181 obliteration: the pace of scientific progress is so rapid, and new findings become so quickly and
182 thoroughly absorbed into the ‘general stock’ of knowledge, that a great deal of work is quickly
183 ‘forgotten’ by the academic community. The phenomenon is particularly noticeable in exact
184 sciences, in which authors seem consistently to build upon relatively recent research, the time lag
185 between an author and the work he cites remaining fairly constant (Van Raan, 2010). At the
186 same time, other scholars have observed the long-lasting impact of ‘classic’ works on the
187 evolution of a field. For instance, Franco Aixelá’s 2013 study of the most cited works in Western
188 Translation Studies (WTS) revealed that almost all the most frequently cited papers were
189 “classics” published well before the 2000s, a finding which appears to suggest that WTS scholars
190 have a marked preference for deepening and widening their understanding of the ages-old issues
191 of translation and otherwise carrying on the intellectual lineage of classical authors.

192

193 The research by the aforementioned authors points to two contrasting patterns of knowledge
194 flow existing in tandem. Merton (1967), Lederberg (1972), Garfield (1977) and Van Raan (2010)
195 identified a scenario whereby knowledge flows at a steady rate, which will be referred to in the
196 remainder of this chapter as perfect research flow. By contrast, Franco Aixelá (2013) has
197 observed deviations from this scenario, along a continuum to the extreme opposite one of
198 research stagnation. The aim in this section was to discover whether or not the CIS community
199 followed this academic tradition of WTS’, and, more generally, to examine how the field’s
200 progress could be illustrated by means of citation analysis.

201

202 **3.2.2 Research methodology**

203

204 Two null hypotheses were tested: the first was that of ‘research stagnation’² — this tests
205 whether new papers are not constantly being cited; and the second was that of ‘perfect research
206 flow’ — this tests whether the citation process is stationary³.

² ‘Research stagnation’ in this context is shorthand for the stagnation of the citation process, whereby new articles are not cited and therefore after a given year the distribution of citations falls to zero. As we shall see in the Results and Discussions section (3.2.3.1), this hypothesis was later rejected. Of course, numerous other factors need to be taken into consideration to determine whether or not a field of inquiry is moving forward. Unfortunately the analysis of these is outside the scope of the present study.

207

208 3.2.2.1 The Hypothesis of Research Stagnation

209

210 Research stagnation occurs when articles published after a given year (t) suddenly cease
211 completely to be cited. One scenario which can lead to this state of affairs is when articles
212 published before year t are so influential that they ‘drown out’ all citations from ones published
213 after it. This hypothesis is rejected if new papers are being constantly cited.

214

215 3.2.2.2 The Hypothesis of Perfect Research Flow

216

217 Perfect research flow occurs when the citation process is stationary. The following example
218 illustrates a case of perfect research flow: for articles published in a given year t , let us suppose
219 that no citations come from year $t-4$ or earlier, and that most citations come from papers
220 published in year $t-3$, with half as many for each successive year down to t itself. Perfect
221 research flow comes about when this distribution of citations is true for all the years t examined
222 in the study.

223

224 A typical scenario that would cause this hypothesis to be rejected would be if a few very
225 influential (‘classic’) articles were published in a given year t_0 and cited more than the average
226 article, even ten years later: in this case the citation process would indeed not be stationary,
227 because in year t_0+10 citations of this article published ten years previously would still be
228 being produced! We therefore would not be dealing with a case of perfect research flow.

229

230 3.2.2.3 Hypothesis Testing

231

232 The aforementioned hypotheses concern the distribution of the citation process. To test them,
233 all the papers published in year t and the years of all citations contained in those papers were
234 identified. The distribution of papers cited in year t was estimated as the average number of

³ A process is said to be stationary if its distribution remains unchanged over time. In the example given in section 3.2.2.2 the distribution of papers cited in year t is said to be stationary if its relation to the previous years (t , $t-1$, $t-2$, etc) does not depend on t .

235 citations per paper published in year t coming from each previous year: $t-1$, $t-2$, $t-3$ and so on.
236 The same methodology was applied to all publication years between 1990 and 2013. Once the
237 distribution of cited papers for each year t was established, it was possible to test whether the
238 figure was stagnant, and, by measuring how it changed from year to year, whether it was
239 stationary.

240

241 These two hypotheses were tested by comparing the performances of two models—one for each
242 hypothesis—to that of a third, namely a varying coefficient model (VCM).

243

244 Varying Coefficient Models (VCMs) are more generalized versions of regression. Regression
245 expresses the value of an output as a combination of different type of input (or predictors). Each
246 input has an associated coefficient which signifies the importance of its contribution to explain
247 the output. In varying coefficient models, the coefficients themselves vary with other variables,
248 which may or may not be connected to the predictors. For example, in the context of a chemistry
249 experiment, we may get very different coefficients in a linear regression of amount of reagent
250 created depending on outside parameters such as temperature. A varying coefficient model
251 would give a better fit: the coefficients in the regression are functions of the temperature (this is
252 not the same as including the temperature as a predictor, since the dependence of reagent created
253 to the temperature is not direct or linear). An overview of the theory behind VCM models can be
254 found in Hastie & Tibshirani (1993).

255

256 We used a Varying Coefficient Model to fit a citation process somewhere between research
257 stagnation and perfect research flow in the following way. In each model the output was the
258 average number of citations per paper published in target year t . For research stagnation the input
259 was the raw source year of the citations (e.g. a paper is published in 1996). For perfect research
260 flow the input was the relative source year of the citations (the relative source year of papers
261 published in year $t-i$ is i). For both of these models the input coefficients were forced to be fixed
262 across target year t . Finally, we fit the third—VCM—model with the same inputs as for perfect
263 research flow, but allowed the coefficients to vary smoothly with source year.

264

265 All three models were fit using a generalized linear model with Poisson link function.
266 Additionally, the VCM was fit using locally weighted least squares and a Gaussian kernel.

267

268 To test the null hypotheses of research stagnation and perfect research flow we examined
269 whether the VCM model fit the data significantly better than either of the first two using a
270 deviance difference test as proposed in Fan, Zhang and Zhang (2001). Table 1 below contains
271 the resulting p-values.

272

273 **Table 1:** Evaluation of VCMs.

274

275 A more detailed description of our statistical methods—model description, fitting procedure
276 and hypothesis tests—can be found online at: http://interpretrainer.com/VCM_Justification.pdf.

277

278 **3.2.3 Results and discussions**

279

280 Figure 1 is the graph representing the distribution of citation processes for MA theses, doctoral
281 dissertations and journal articles in different years.

282

283 Figure 1: Normalized incoming citations for three strands of CIS research

284

285 **3.2.3.1 Hypothesis of Research Stagnation**

286

287 Figure 1 indicates definite movement over time for the incoming citation curves. In panel 4 of
288 Figure 1 concerning all CIS publications, if all the curves had looked the same, this would have
289 supported the hypothesis that the field of CIS is static. This is not the case here: the ‘peaks’ in the
290 curves move forward from year to year and do not ‘stagnate’ at a given year. In sum, the figures
291 suggest that CIS research is moving forward.

292

293 In addition, the hypothesis of research stagnation was rejected on statistical grounds: more
294 recent CIS publications were constantly being cited, as opposed to classic papers receiving the
295 majority of citations as time went by, and that caused the model corresponding to research

296 stagnation to fit less accurately the data than did the VCM model, as demonstrated by the very
297 low p-values for the corresponding tests⁴ (see http://interpretrainer.com/VCM_Justification.pdf
298 for more information).

299

300 While newer citations may not necessarily contain innovation — they may simply restate the
301 positions found in classic works — there is assuredly some foundation to Zuckerman’s argument
302 (1987) that the use of more recent citations nonetheless indicates that academic inquiry is
303 moving forward. The argument is as follows: a cited paper (Paper A) gains influence when it is
304 cited by multiple authors; however, authors may sometimes be inclined to cite other more recent
305 papers that specifically refer to Paper A, as opposed to citing it directly. While these more recent
306 publications may or may not generate new findings or innovative material, they effectively serve
307 as an intellectual conduit connecting contemporary researchers with past foundational work.
308 Paper A has become so thoroughly incorporated into the field’s stock of knowledge, has become
309 so fundamental to it, that authors feel no need to make explicit reference to it. Therefore, the
310 rejection of the research stagnation hypothesis indicates that contemporary researchers build on
311 more recent work and that academic enquiry is moving forward.

312

313 Even though it was both visually and statistically confirmed that CIS is moving forward,
314 whether it has been doing so at a steady pace remains an open question. The rejection of the
315 research stagnation hypothesis says nothing about how research evolves, and notably if the flow
316 of research is ‘perfect’ in the sense where the distribution of citations is always the same from
317 year to year, and for that reason the hypothesis of perfect research flow needs to be tested.

318

319 **3.2.3.2 Hypothesis of Perfect Research Flow**

320

321 Perfect research flow is the opposite extreme of stagnation, and it means that papers are cited in
322 exactly the same fashion every year. Figure 1 also enable us to grasp visually the rejection of the
323 stationarity hypothesis. If this hypothesis were true, this would imply that the lines shown in the
324 plots did not change with source year. This is clearly not the case here.

⁴ ‘The corresponding tests’ refers to those that compare the research stagnation model against the VCM model to see if the former fit data better than the latter. This hypothesis was rejected for all document types: MA theses, journal articles and PhD dissertations.

325

326 Moreover, a statistical analysis was conducted to validate visual intuition concerning the
327 hypothesis of perfect research flow. Indeed, this hypothesis was statistically rejected, because the
328 Varying Coefficient Model fit better to the citation data than did the model corresponding to
329 perfect research flow (described in detail at http://interpretrainer.com/VCM_Justification.pdf).
330 Once again, this is demonstrated by the very low p-values of the corresponding tests in Table 1.

331

332 3.2.3.3 Hypothesis Testing and Graphical Interpretations

333

334 To test both of the previously mentioned hypotheses a VCM model was used first to describe
335 the data as accurately as possible, then this model's performance was tested to compare it with
336 those of the models corresponding to each hypothesis.

337

338 For each year t , a spline was fit to incoming citations as a function of $|t-i|$, where i was the year
339 of publication of the cited article. The VCM model was constructed so that it would be easy to
340 control the variation of the coefficients over time.

341

342 The resulting graphs (see Figures 2 - 4) can be likened to a frame-by-frame movie of the
343 evolution of incoming citations over time.

344

345 Figure 2: Trends in citations for research papers

346

347 Figure 3: Trends in citations for MA theses

348

349 Figure 4: Trends in citations for doctoral dissertations

350

351 The red line is the fit for the VCM model and can be considered the average citations count for
352 that year; the blue dots are the actual number of citations produced in each year; and the gray
353 shaded areas represent a 95% confidence interval for the red line. The gray headers show the
354 year under consideration — for example, '2000' means that all the papers written in 2000 were

355 examined to ascertain the number of citations in them dating from 2000 (t), 1999 ($t-1$), 1998 ($t-$
356 2), and so forth.

357

358 On examining the incoming citation data it was observed that recent papers were regularly cited
359 within an interval of a year or two — this trend was particularly obvious from 2009 to 2012.
360 Moed (2005) has argued that an author might include a certain reference not only because its
361 content fits the flow of an argument, but because he believes the scholar he is citing has gained a
362 certain stature in the field and will lend credibility to his own ideas. For example, it would be
363 more credible to cite the definition of empirical research by a scholar who has conducted
364 extensive studies of that type than by one whose focus is purely theoretical. The finding that
365 recent papers are cited so soon indicates that newer research has a more or less instant impact on
366 the latest studies and that CIS research is in a state of continuous progression. It was also
367 remarked that, in disregard of the 1-2 year rule mentioned above, citations from material
368 published in 1990 were made in CIS papers throughout the period under study, suggesting that
369 that year may have seen the publication of particularly influential material, whose impact on
370 research has been especially long-lasting. On further examination of the incoming citations, Hu
371 Gengshen's *An overview of interpreting research in China* stood out as the aforementioned
372 material. Hu's paper took a scientometric approach to assessing the themes and trends in
373 interpreting research. From the Y axis it was also clear that many more citations were being
374 made in later years, probably because the number of CIS papers being written was increasing
375 year on year.

376

377 The situation for MA theses was slightly different from that of journal articles, though research
378 was moving forward here too. These authors were somewhat hesitant to cite recently completed
379 theses, preferring those produced at least three years previously, which they could be sure, had
380 been adopted by the academic community and become established. It was also noticeable that
381 material produced in 1996 was cited by numerous MA authors in all subsequent years,
382 suggesting that some very influential work was produced in that year. Detailed analysis revealed
383 that work to be Ru Mingli's thesis *Interpreting quality and the role of the interpreter from the*
384 *perspective of users*, which was produced under the supervision of Chen Yongyu. It should be
385 noted, however, that MA thesis authors cited their predecessors' work far less often than the

386 authors of research papers did theirs: in 2010, for example, research papers produced in 2008
387 were cited no fewer than 148 times; the same figure for MA theses was a mere 22. There are two
388 possible reasons for this phenomenon: (1) a number of researchers (Lawrence 2001; Harnad &
389 Brody 2004; Hajjem et al. 2005) have identified that open-access articles receive a substantially
390 higher number of citations than those that require a subscription — this is true across many
391 disciplines including computer science, physics, sociology and psychology. Proceeding from
392 their findings, it is reasonable to speculate that the difficulty — and expense — of obtaining
393 access has contributed to the significantly lower number of CIS theses being cited in comparison
394 to research papers. (2) In addition, in the academic world MA theses are generally considered to
395 be of lower quality than research papers, which have gone through rigorous peer review.

396

397 Given that the total number of doctoral dissertations was only 32, little in the way of trends was
398 observable. It should be noted, however, that a particular doctoral dissertation produced in 2008
399 was consistently quoted by later PhD authors in the period 2010-13 — this was Gong
400 Longsheng's *An analytical study of the application of Adaptation Theory in interpreting*, written
401 under the supervision of Dai Weidong. Gong is such a well-established and visible academic
402 within the CIS community⁵, that it is hardly surprising that his work might attract a large number
403 of incoming citations.

404

405 To conclude, two null hypotheses were both visually and statistically rejected: research
406 stagnation and perfect research flow. To perform those tests two models corresponding to each
407 of the hypotheses, and a third, the Varying Coefficient Model, were constructed. The three were
408 tested to see how well they fit the CIS citation data. Both hypotheses were rejected, because the
409 first two models performed poorly in comparison with the VCM model. Analysis of the citations
410 yielded enough evidence to say that this field is going forward, though not at a constant pace.

411

412 **3.3 Study 2**

413

414 **3.3.1 Research Question**

415

⁵ Gong served as an associate dean of the Graduate School of Business at SISU, has supervised nearly 30 MA interpreting students, and was involved in developing the Shanghai Interpretation Accreditation Test.

416 **What are the most frequent citation types? Do they differ based on language of origin**
417 **(Chinese vs. English) and document type (papers, MA theses and doctoral dissertations)?**

418

419 While quantitative analysis of the academic influence of individual authors, institutions,
420 geographical regions and publications may shed light on the entire CIS landscape, some
421 qualitative analysis of citation types is necessary to provide insight into the interactions between
422 the various schools of thought and research practice that constitute the field.

423

424 **3.3.2 Research methodology**

425

426 The citations were labeled according to the way each cited paper was used by the referring
427 paper. After an initial pilot study,⁶ a citation classification system was developed to evaluate how
428 authors were cited in the CIS literature (see Table 2).

429

430 **Table 2:** Citation classification system

431

432 A random sampling without replacement was conducted on each of the six citation databases of
433 CIS: English citations in MA theses, research papers, and doctoral dissertations; and Chinese
434 citations *ibidem*. This form of sampling was used because it leads to more accurate results than
435 sampling with replacement, thanks to an effect known in the simulation literature as ‘variance
436 reduction’ (Rao 1963). The minimum sample size was fixed at one large enough for detecting
437 any statistically significant difference in the proportions of each citation type between Chinese
438 and English. Given that there was no prior knowledge about whether the number of Chinese
439 citations would be larger than that of the English ones, or vice versa, a power calculation for a
440 two-sided two-sample proportion test was conducted for each of the six citation databases in
441 order to give a 95% chance of detecting a difference of 10%⁷ between two proportions at the

⁶ Building on the studies of Gile (2006) and Nasr (2010), the author conducted a pilot study of citation types in CIS by randomly sampling a total of 239 in-text citations from Chinese papers, theses and doctoral dissertations. After labeling these according to the methods described in Gile’s pilot research project (2006), a collaborator who was familiar with the topic was asked to give a ‘second opinion’ by labeling them again himself, with the aim of ensuring a greater measure of objectivity and reliability. These labelling activities were completed in four installments. The sequential analysis was restricted to 239 citations because by that point the author had sufficient knowledge of regularly occurring citation types in CIS, and the differences in labeling between the author and the collaborator were minimal.

⁷ If the true difference in proportions were, for example, 1%, no difference would be detectable unless the sample

442 0.05 significance level. The minimum number of samples required for each database (648 as
443 determined by the power calculation) was collected, analyzed and labeled.

444

445 The majority of the in-text citations were expected to belong to a single citation type, but some
446 belonged to more than one — this occurred primarily when an author cited a particular source at
447 different places in his text. If one of these multi-category observations was selected for inclusion
448 in the random sample, that citation needed to be assigned to a *single* category to maintain
449 consistency. To address this, one of the assigned categories with equal probability was selected
450 at random to decide which category the citation should have been assigned to. Though it may
451 appear crude, assuming equally probable categories as a first approach yields good results, and is
452 frequently used (Kemphorne 1952; Freedman 1997; Schulz & Grimes 2002) when there is no
453 prior knowledge of the distribution of the data.

454

455 Working from the results of the power calculation, which gave an effective way of sampling;
456 confidence intervals of 95% were constructed for the proportion of each citation type. It was
457 expected that N/A would be the most frequently used citation type across all three categories of
458 CIS publication in both Chinese and English. Citation practice in the Chinese academic
459 community is distinctly different from that of the Western world: large numbers of scholars list
460 in their bibliographies the literature they consult while conducting research, even if it is not
461 directly cited in the body of their texts. However, according to most Western style guides, such
462 as that of the American Psychological Association (APA), authors are required to cite the works
463 of those who have directly influenced their research, and every resource in the bibliography must
464 have a corresponding in-text citation, with the exception of some classics such as the Bible (APA
465 2010). Because of the lack of textual references to these N/A citations it is not easy to code them.
466 There may be limits to the space available to authors for recording references, meaning that not
467 all the works that have influenced them will make it to the final list, so it is reasonable to assume
468 that they are painstaking in their choice of what to include. Those citations that are listed,
469 including those in the N/A category, must have had a major influence on the author, be it factual,
470 theoretical or inspirational. Because of the different impacts that Western and Chinese literatures
471 have had on CIS, the proportions of N/A for English and Chinese citations were expected to

sizes were at least 64,974! The entire population for the present study comes nowhere near this size. A 10% difference was chosen because it allowed the author to work with a reasonably sized sample.

472 differ — analyzing these proportional differences might help to illustrate the ways in which
473 Eastern and Western thought have influenced CIS.

474

475 Another expected finding was that authors would be frequently cited for their Ideas and
476 Prescriptive and Non-prescriptive Opinions; this might come as a surprise to those from
477 disciplines where opinion-based citations are not common. These citations of Ideas and Opinions
478 are prevalent because practicing interpreters are highly respected in the CIS community. This is
479 corroborated by the fact that numerous professionals with no background in research are
480 regularly invited to serve as keynote speakers at the biannual National Conference and
481 International Forum on Interpreting, the most important research conference in China. Tangential
482 Research was another citation type expected to be in frequent use, because scholars may often
483 feel obligated to make ‘ceremonial citations’, i.e. referencing the leading experts in the field
484 without actually having read their research (Meho 2006). At the other end of the spectrum,
485 research methodology and findings were expected to be in much less frequent use, because non-
486 empirical research still accounts for the overwhelming majority of published works in CIS.

487

488 **3.3.3 Results and discussions**

489

490

491 Figure 5: Proportion of the top 10 citation categories with confidence bars across all databases

492

493 When a fair and unbiased random sample is taken from a large population, the law of large
494 numbers ensures that the sample average for any category ought to be close to the true value of
495 the mean in the total population. Confidence intervals represent intervals where the real average
496 proportion of each category will be with some probability; in the current study, this probability
497 was set to 95%. For example, in the sample for the present study (3,888 citations), nearly 45%
498 were labeled N/A. Therefore the 95% confidence interval for all the N/A citations was [42% ;
499 45.1%], a finding which appears to suggest that almost half of the works listed in the
500 bibliographies of CIS authors did not appear in the body of the text. The prevalence of N/A
501 references indicates that certain cited authors may not necessarily be linked directly to the
502 research of those citing them, despite having played an instrumental role in shaping their outlook

503 on interpreting or influencing their professional training. For example, a further analysis revealed
504 that 75.3% of the references to Mei Deming and 85.6% of those to Zhang Weiwei belonged to
505 the N/A category; their cited works are the leading interpreting textbooks in China, though not
506 regarded as theoretical or empirical contributions to CIS research. The second most popular
507 citation type (theoretical analysis) stood at 7.5%; the corresponding 95% confidence interval was
508 [6.6% ; 8.3%]. From this finding it is reasonable to speculate that theoretical research has played
509 a crucial role in shaping CIS. It was also observed that 5.8% of citations belonged to the research
510 finding category (95% confidence interval: [5.1; 6.5%]). This is interesting because that citation
511 type is generally associated with empirical research. Its being the third most frequently used type
512 seems to indicate that CIS authors were also keenly aware of the importance of empirical
513 research, and consciously analyzed how their research could amplify the findings of previous
514 scholars.

515

516 An examination was also made of the distribution of citation types by the following methods:

517

518 (1) Citation type distribution for all Chinese citations (see Figure 6)

519 (2) Citation type distribution for all English citations *ibidem*

520 (3) Top ten citation types for all Chinese citations in theses, dissertations and papers (see
521 Figure 7)

522 (4) Top ten citation types for all English citations in theses, dissertations and papers *ibidem*

523 (5) Citation types for MA theses, dissertations and papers (see Figure 8)

524

525

526 Figure 6: Proportions of all English and Chinese citation type distributions with confidence bars.

527

528 Confidence intervals of 95% were constructed to compare the differences in the proportions of
529 each category between Chinese and English references. If for a given category the means of the
530 two populations have non-overlapping confidence intervals, this indicates a statistically
531 significant difference between the Chinese and English citations – non-overlapping 95%
532 confidence intervals guarantees a test for differences at alpha level of 0.05 (Knezevic 2008). For
533 example, the proportion of N/A citations was [46.2% ; 50.6%] for Chinese against [36.6% ;

534 41.0%] for English. The differences in proportions suggest that English references listed in
535 bibliographies are more likely to have corresponding in-text citations than their Chinese
536 counterparts, which would indicate that CIS authors are more indirectly influenced by their
537 Chinese than their Western colleagues.

538

539 The analysis also revealed that there was a significant difference in the Theoretical Analysis
540 citation type between Chinese (95% CI: 4.1-6.0%) and English (95% CI: 8.5-11.2%) (Figure 7).
541 This would appear to indicate that, in cases of theoretical discussions, CIS authors are roughly
542 twice as likely to cite English authors as their Chinese colleagues. In addition, it was found that
543 Prescriptive Opinions (95% CI: Chinese 3.7-5.6% vs. English 2.1-3.6%) and Textbook citations
544 (95% CI: Chinese 1.6-2.9% vs. English 0.1-0.5%) were less common in English than in Chinese
545 citations, while Research Findings were more common (95% CI: Chinese 3.1-4.8% vs. English
546 6.5-8.8%). While advice from all practicing professionals is highly valued in the global
547 interpreting community, these findings appear to suggest that the opinions of Chinese
548 interpreters carry more weight with CIS authors than those of their Western counterparts.
549 Textbooks are usually seen as repositories of established fact rather than sources of cutting-edge
550 ideas. The fact that Chinese textbooks are cited more often than Western ones highlights that CIS
551 researchers frequently turn to them for well-established facts.

552

553 The most frequently occurring category of Chinese citation besides N/A was Characterization
554 (95% CI: [4.6 ; 6.6%]). Given that experience-based, intuitive writing was dominant in CIS'
555 early developmental stage, and that practicing interpreters often resorted to summarizing the
556 features of a phenomenon or idea rather than theorizing or providing empirical support, its
557 popularity is understandable. Conversely, the most frequent category in English citations after
558 N/A was Theoretical Analysis (95% CI: 8.5-11.2%), which suggests that CIS authors were
559 influenced by the theoretical work of Western authors.

560

561

562 Figure 7: Proportions of the top ten citation types for all Chinese and English citations in theses, dissertations and
563 papers

564

565

566 Figure 8: Proportions of all citation types for MA theses, dissertations and papers

567

568 From this point forward the citation distribution in each document type was examined, to
569 spotlight the differences in how different sub-groups of CIS authors make bibliographic
570 references. Citation practice differed widely across the document classes. In MA theses
571 statistically significant differences between Chinese and English references were found for the
572 following citation types: N/A (95% CI: 47.1-54.7% for Chinese vs. 35.6-43.2% for English),
573 Tangential Research (95% CI: 3.7-7.1% for Chinese vs. 0.3-1.9% for English), Theoretical
574 Analysis (95% CI: 2.1-5.0% for Chinese vs. 12.9-18.5% for English) and Textbooks (95% CI:
575 1.5-4.0% for Chinese vs. 0-0.5% for English). The finding for N/A tallies with the earlier result
576 for all citations. As for the Tangential Research type, the result suggests that Chinese authors'
577 research is more frequently mentioned in passing without specific reference to its contents than is
578 the case for Western authors. One might wonder if some thesis authors cite their compatriots as a
579 way of paying tribute rather than because their works inspire or influence them. In addition, this
580 finding is in line with our interpretation of the differences in proportions for the N/A category
581 between Chinese and English references. Of course, there is also the possibility that thesis
582 authors prefer a style of literature review that summarizes more than it analyzes. It is worth
583 noting that no statistically significant differences were observed between Chinese and English
584 references for citation types generally associated with empirical research, such as Research
585 Methodology or Findings.

586

587 It was also revealed that Theoretical Analysis was the second most popular type of all thesis
588 citations, though English authors were far more frequently referred to than Chinese for this
589 category. Its popularity across both Chinese and English strongly suggests that theoretical
590 research is influential on Chinese thesis authors. It was somewhat surprising to find that citing
591 someone for their definitions was a moderately popular citation type (English: 7.9-12.5%;
592 Chinese: 3.4-6.8%) — one might have expected researchers mainly to cite others for their
593 research findings or theories, rather than regularly resorting to them for the definitions of certain
594 terms. Close examination of the contexts in which this type of citation occurs revealed that a
595 significant number of MA students reviewed the history of interpreting at the beginning of their

596 theses, citing Western researchers to define various types of interpreting and clarify the
597 differences between it and translation.

598

599 In journal articles and conference proceedings there were statistically significant differences
600 between Chinese and English references for the Prescriptive Opinion (English<Chinese) and
601 Theory citation types (English>Chinese). This finding suggests that in developing their work
602 CIS article authors were more likely to turn to Western scholars for theories and models and to
603 their Chinese colleagues for intuitive understanding of interpreting. It is worth remembering here
604 that the preference for citing Chinese colleagues for Prescriptive Opinion was also observed in
605 theses. It is understandable that Western scholars are more often cited for Theory, because the
606 first generation of Chinese SI trainers received their education in Brussels — theories such as the
607 Interpretive Theory of Translation and the Effort Models have served as the foundations for
608 many a Chinese author's research. It should be noted here that unlike the earlier findings, no
609 statistically significant difference was observed in N/A between English and Chinese references
610 in research papers⁸; this might be explained by the fact that the comparison was made on a
611 smaller sample for papers (the average number of citations in papers was 10, compared to 43 for
612 theses and 278 for dissertations).

613

614 In doctoral dissertations the following citation types yielded statistically significant differences
615 between Chinese and English references: N/A (Chinese>English), Research Findings
616 (English>English), Concepts (English>Chinese), and Theory (Chinese>English). As in the
617 dissertation category, there were statistically fewer corresponding in-text citations for Chinese
618 references than for English ones, which is consistent with all previously discussed findings in the
619 overall, article and thesis categories. It should be noted that the proportion of Research Findings
620 was higher here than in any other document type examined. This suggests that PhD students
621 particularly rely on predecessors' empirical findings to shape their own work.

622

623 In sum, CIS researchers displayed different citation behavior across languages and document
624 classes, and no particular citation type yielded significant differences between Chinese and

⁸ The statistic of a two-sample z test is 0.79, which is smaller than the critical value of 1.96. Thus, there is no evidence to suggest that there is a statistically significant difference between the proportions of English and Chinese N/A citations.

625 English references across all three document classes. However, the N/A citation type was more
626 frequently used in the Chinese references of theses and doctoral dissertations than in the English
627 ones, while the opposite was the case for Theory. Other than N/A, no citation type occurred more
628 than 20% of the time across languages and document classes, suggesting that research is cited in
629 diverse ways in the CIS community and no particular citation type is predominantly used.

630

631 **3.4 Study 3**

632

633 **3.4.1 Research question**

634

635 **What different effects does the choice of empirical vs. theoretical research have on the use**
636 **of citations in the three document types?**

637

638 Citations illustrate a dynamic relationship between source and target authors; identifying
639 whether a document is being cited for its methods, concepts or theories illustrates how
640 researchers interact with and influence one another. As observed by Garfield (1979), a
641 comprehensive survey of citation types could provide useful information on the structure and
642 evolution of a science. When a source author is cited for his concepts, ideas or opinions, he is
643 typically engaged in theoretical research, while citations of methodology and findings are
644 typically taken from empirical research (Gile 2006). An examination of the shares of citations
645 that relate to empirical vs. theoretical research would shed light on the relative influences that the
646 two methods have in the three categories of CIS publications.

647

648 3.4.2 Research methodology

649 The analysis for this research question proceeds from the assumption described in section 3.4.1
650 that certain citation types (Research Methodology and Finding) are typically associated with
651 empirical research, while others (Concepts, Ideas and Opinions) are linked to theoretical studies.

652

653 It was expected that doctoral dissertations might contain a greater proportion of empirical
654 citations than MA theses and research papers. Furthermore, it was predicted that citations
655 relating to theoretical research would be most frequently found in papers, followed by theses and

656 dissertations. These predicted outcomes were based on the fact that 80% of dissertations were
657 empirical (compared with 50% of theses and 20% of papers), indicating that empirical
658 methodologies were the preferred research approach among doctoral students, whereas paper
659 authors, who were mostly established academics, preferred theoretical research.

660

661 First it was necessary to determine how many data points would be required to detect a 10%
662 difference between two proportions at the 0.05 significance level. Given that there is reason to
663 believe that the differences in the proportions of empirical and theoretical citations are
664 directional, a power calculation for a one-sided two-sample proportion test was conducted to
665 determine the minimum number of citations that would be needed as samples from each of the
666 three categories of CIS publications to guarantee enough statistical power of the test. Since there
667 was found to be no relationship between the hypotheses in Questions 2 and 3, re-using the same
668 samples is not an issue. The minimum sample size for Question 2 was 648 for every possible
669 combination of language and document type, whereas the same number for Question 3 was 755
670 for each category of document. The actual sample of 1,296 (combining the sampled Chinese and
671 English citations in each document type) easily exceeded the necessary minimum for Question 5,
672 further increasing the power without increasing a type one error. Once all the required citations
673 were labeled, a two-proportion z-test was performed, yielding p-values. The z-test examined
674 whether the proportions of citations associated with theoretical research were equal to those
675 associated with empirical research.

676

677 **3.4.3 Results and discussions**

678

679 A two-proportion one-sided z-test was used to evaluate whether the proportion of empirical
680 citations was greater than non-empirical ones. The test yielded the following p-values for the
681 four tests (p-values were rounded to 3 digits): the comparison between the proportion of
682 Research Methods and Findings cited by articles and MA theses (empirical citations) was not
683 significant ($p = 0.532$). However, the comparison between doctoral dissertations and theses was
684 significant ($p < 0.001$). The proportions for citations of research methods and findings in theses,
685 articles and doctoral dissertations were 0.064, 0.065 and 0.124 respectively.

686

687 (1) Articles > theses IS NOT significant, $p = 0.532$

688

689 (2) Doctoral > theses IS significant, $p < 0.001$

690

691 It was observed that doctoral dissertations cited research methods and findings more than
692 theses, therefore the null hypothesis that the reverse would apply can be rejected; but there was
693 little evidence to support the same claim for theses as compared to journal articles, therefore that
694 null hypothesis cannot be rejected. However, given that the p-value in hypothesis (2) is
695 significant, it can be stated with confidence that doctoral dissertations cited research methods and
696 findings more than papers. The data suggest the following relations:

697

698 **Research methods and findings:** dissertations > (theses ? journals)⁹

699

700 It was observed that theses used fewer citations of Concepts, Ideas and Opinions (theoretical
701 citations) than papers, but there was scant evidence to suggest that doctoral dissertations used
702 fewer such citations than theses. The overall proportions for these citations in the three types of
703 publication were 0.094, 0.086 and 0.133.

704

705 (3) Theses > doctoral IS NOT significant, $p = 0.246$

706

707 (4) Articles > theses IS significant, $p < 0.001$

708

709 However, the present analysis demonstrates that the differences between the two categories are
710 significant, which is in line with the idea that theses use fewer concepts:

711

712 **Concepts, ideas, and opinions:** (dissertations? theses) < journals

713

714 Because questions (1) and (3) compare MA theses and research papers, and questions (2) and
715 (4) compare doctoral dissertations and MA theses, and because there is not a new random sample

⁹ 'Theses? journals' means that the null hypothesis that theses have fewer research methodology citations than articles cannot be rejected, therefore the author cannot comment on any relationship that might exist between theses and journals in this specific case. Unlike a two-sided test, where the null hypothesis is equality, the null hypothesis for our one-sided test is less than or equal to zero.

716 for each test, the tests are correlated. To control the familywise error rate, the present author
717 implemented the Bonferroni-Holm correction method, a sequential method where the p-values
718 do not have to be adjusted but can, rather, be compared to a different significance level to keep
719 the familywise error rate for all of the tests at 0.05. Without such correction, there would be an
720 increased chance of rejecting correct null hypotheses, thus increasing Type-I errors.

721

722 After the correction, even the two smallest p-values remained significant when compared to the
723 new cutoffs:

724

725 (2) Research methods and findings: doctoral > theses IS significant at 0.0125, p-value: 7.75e-08

726 (4) Concepts, ideas, and opinions: articles > theses IS significant at 0.0167, p-value: 0.000639

727

728 This strongly suggests that the previous findings — that dissertations cite more research
729 methods and findings than theses, and that dissertations and theses cite fewer concepts, ideas and
730 opinions than papers — still hold true even after adjusting for familywise errors. In other words,
731 empirical research has a greater influence on how doctoral scholars cite papers than it does on
732 thesis and paper authors; and theoretical research has a more significant impact on how paper
733 authors make citations than it does on MA and doctoral authors. This finding is interesting
734 because it indicates that data-driven research is more popular among MA and doctoral students,
735 whereas theoretical research is favored by established academics. If MA and doctoral students
736 represent the future of CIS, one can expect empirical research to continue to expand its sphere of
737 influence in the foreseeable future.

738

739 **4. Conclusion**

740

741 The author hopes that this scientometric survey has demonstrated the merits of blending
742 quantitative with qualitative analysis to paint a panorama of Chinese Interpreting Studies.
743 Citation data was used to measure the progress of CIS: the field is a dynamic one with new
744 papers being constantly cited, though a few influential older papers have withstood the process
745 of ‘obliteration’. Citation sampling and labelling were employed to describe how scholars exhibit
746 different citation patterns across languages and document types, and how authors’ choice of

747 empirical or theoretical research variously influences journal articles, MA theses and doctoral
748 dissertations.

749

750 Thanks to its comprehensive collection of data, the study did not face the issues of sample size
751 typically associated with quantitative analyses of interpreting studies (IS) in the past. In the West
752 only a few hundred individuals are dedicated to interpreting research; by contrast, no fewer than
753 3,500 Chinese scholars are documented in this study's database: this wealth of available data
754 made it possible to adopt some of the latest statistical techniques to assess the evolution of CIS.
755 The qualitative elements of the study served to spotlight unique patterns of behavior exhibited by
756 its researchers when citing their predecessors.

757

758 The focus of this paper being IS, no attempt was made to explore translation-related
759 publications. Given that translation studies (TS) has a longer history and many more participants
760 than IS in China, an interesting future line of inquiry would be to research the themes and
761 patterns of the former, so as to offer a balanced view of how the whole discipline of translation
762 and interpreting studies has developed and is developing. According to Franco Aixelá (2013), it
763 takes at least five years for Western TS publications to receive any citations, in sharp contrast to
764 the 1-2-year rule for Chinese papers. It is reasonable to predict that Chinese TS, with its strong
765 focus on classic authors and their theories, may need much more time to gain any traction.
766 However, as is the case for IS, with its increasing influence from neighboring disciplines such as
767 psychology and linguistics, the time lag between citing and cited papers in TS is greatly
768 shortened as time goes by.

769

770 Also, with the ever-increasing level of academic exchange between East and West, a
771 comparative study of the differences and similarities between the two would provide valuable
772 insights to policy-makers charged with shaping the future direction of academic research. In the
773 West, Chesterman (1998) observed that one of the most important trends in TIS has been the
774 shift from theoretical to empirical research. Pym (2010) further argued that the regurgitation of
775 'authoritative' insights without empirical testing does not help advance the field. It would be
776 interesting to seek out empirical evidence to corroborate Chesterman's observations regarding the
777 trends in Western TIS and to investigate whether empirical studies have a tangible effect on

778 journal articles, theses and doctoral dissertations in the field. If the answer to that question turned
779 out to be negative, the design of curricula for training future TIS researchers might need to be
780 reconsidered, and in particular their empirical components reinforced. On the Chinese front,
781 Wang and Mu found (2009) that though the number of publications was on the rise, many were
782 no more than speculative and personal reflections regarding training. Thanks to its much more
783 comprehensive and recent data-set, this study has found that the current CIS landscape is a
784 complex and rapidly changing one: while journal articles and conference proceedings are still
785 dominated by theoretical analysis, doctoral studies have been heavily influenced by empirical
786 research.

787

788 Interpreting is a profession whose actions can have real-world consequences in diplomatic,
789 military, commercial, and judicial fields, among many others. For this reason alone, the ideas
790 and theories in use need to be tested, adjusted and improved in the real world so that aspiring
791 interpreters may hone their skills with the maximum of efficiency and efficacy. The findings of
792 this study have demonstrated that CIS has come a long way from its infancy. While much more
793 work undoubtedly needs to be done to improve the overall quality of CIS research, it is
794 reassuring to have learned that scholars in the field have begun to appreciate the importance of
795 empiricism and that as a result the general trend of the discipline is moving in the right direction.

Citation classification system

1 **Table 2:** Citation classification system

Citation types	Definitions
Prescriptive opinion	The cited author explicitly expresses his position on an issue or issues, and directs readers. Statements of this nature often rely on modals such as <i>ought</i> , <i>should</i> and <i>must</i> .
Non-prescriptive opinion (Claim)	The cited author expresses a personal view but <i>without</i> directing the reader.
Assessment	The cited author gives an evaluation of an issue or issues he deems important.
Concept	The cited author puts forward a detailed idea.
Rules/standards	The cited author talks about principles of conduct or codified regulations.
Theory/model	The cited author creates a group of propositions that are used to explain or predict certain phenomena.
Theoretical analysis	The cited author examines a phenomenon, concept or behavior in abstract terms, basing his reasoning on existing theoretical frameworks.
Idea	The cited author's thought is non-technical and lacks the detail found in 'concepts', 'theories' and 'theoretical analysis'.
Tangential Research	The cited author has made a detailed study of a particular subject in the hope of obtaining new information or deepening understanding.
Research method	The cited author adopted a particular approach to uncovering new information or advancing understanding.
Research finding	The cited author draws factual or empirical findings from a study.
Non-TS factual citation	The cited author covers factual information outside the scope of Translation Studies.
TS-related factual citation	The cited author alludes to factual information that falls within the scope of Translation Studies.
General Principle	The cited author talks of fundamental 'truths' which fall short of being absolute.
General Report	The cited author observes and describes a phenomenon or behavior.
Qualification	The cited author sets parameters or defines the limitations of a phenomenon.
Definition	The cited author explains a phenomenon, behavior or concept in terms of its unique characteristics.
Characterization	The cited author describes the features of a particular issue or concept.
Textual	The citation is of an author's textbook or other instruction manual.
Non-theoretical analysis	The cited author makes a face-value examination of certain issues or phenomena without the use of theories.
Famous quotes	The cited author quotes a well-known person's words to emphasize a point.

Miscellaneous	Any citations that do not fit into the aforementioned categories.
Not available	A bibliographic reference does not correspond to any of the in-text citations in a paper.
