**Background,** C1q/tumor necrosis factor-related protein-3 (CTRP3) has diverse functions: anti-inflammation, metabolic regulation, and protection against endothelial dysfunction.

**Methods.** The plasma level of CTRP3 in autistic patients (n=32) was compared to that in controls (n=37) using ELISA. **Results.** CTRP3 was higher (24.1% with  $P<0.05$ ) in autistic patients than in controls. No association was observed between CTRP3 and the severity of the disorder using the Childhood Autism Rating Scale (CARS). A positive correlation between CARs and the age of patients was reported. Receiver operating characteristic (ROC) analysis demonstrated a low area under the curve (AUC) for all patients (0.636). Low AUCs were also found in the case of severe patients (0.659) compared to controls, but both values were statistically significant ( $P\leq 0.05$ ). Despite the small sample size, we are the first to find an association between CTRP3 and autism spectrum disorder (ASD).

**CTRP3 as novel biomarker in plasma of Saudi children with autism spectrum disorders**

# Abstract

**Background.** C1q/tumor necrosis factor -related protein-3 (CTRP3) has diverse functions: anti-inflammatory, metabolic regulation, and protection against endothelial dysfunction.

**Methods.** Plasma level of CTRP3 in autistic patients (n=32) was compared to controls (n=37) using ELISA.

**Results.** CTRP3 was higher (24.1% with  $P<0.05$ ) in autistic patients compared to controls. No association observed between CTRP3 and severity of the disorder using Childhood Autism Rating Scale (CARS). A positive correlation between CARS and age of patients was reported. Receiver operating characteristics analysis (ROC) demonstrates low area under the curve (AUC) for the total patients (0.636), it also presents low AUCs in case of severe patients (0.659) compared to controls but both values were statistically significant ( $P\leq0.05$ ).

Despite the small sample size, we are the first to find association between CTRP3 and autism spectrum disorder (ASD).

## Keywords:

Autism spectrum disorder, biomarker, C1q/tumor necrosis factor (TNF)-related protein (CTRP3), Childhood Autism Rating Scale, Receiver Operating Characteristics (ROC).

# Introduction

Autism spectrum disorder (ASD) is a biologically neurodevelopmental disorder afflicting about one in every 59 children, and it is expected to increase globally. (Bjørklund et al. 2018). The increasing prevalence of ASD made it a high priority for scientists and health care providers, and has also attracted the public attention (Sheldrick and Carter 2018; Xu et al. 2018). It is diagnosed behaviorally based on a triad of symptoms, including impairment in communication, impairment in sociability and abnormal and stereotypic behavior (Bjørklund et al. 2018). These core symptoms can be detected before the age of three years and are lasting for the whole lifetime (Andres 2002).

Recent studies mainly focus on the mechanism and the pathogenesis of ASD. Many biomarkers which are noninvasive quantitative measures gave precise indication to certain mechanisms can be used to give better

understanding of the etiological mechanisms of autism and there after its treatment. Blood is considered as a potential source for the detection of many diseases because it contains huge numbers of proteins associated with the physiology or pathology of diseases (Yao et al., 2021). Finding valid and predictive biomarkers for this disorder will improve earlier diagnosis and intervention. Until now no specific biomarker was found to cause autism, but comparing autistic patients with peers without ASD can give better understanding of the disease.

Many biomarkers were related to ASD and had significant role in its pathogenesis, immunological/inflammatory markers are considered one of these biomarkers. Moreover, it was found that some ASD biomarkers were generated from lipid abnormalities (El-Ansary and Al Dera 2016).

C1q/tumor necrosis factor (TNF)-related proteins (CTRPs) family a paralogue of adiponectin, was discovered. There are 15 members extending from CTRP1 to CTRP15, and each member is composed of four different domains, an N-terminal signal domain, a short variable peptide, a collagen-like peptide, and a C-terminal globular like C1q domain (Ahima et al. 2006). Both CTRPs and adiponectin are a portion of the C1q/TNF protein, which are higher in molecular weight due to the presence of extra C1q domain proteins (Yi et al. 2012).

The CTRP family members has multiple physiological effects on metabolism, inflammation, protection against endothelial dysfunction and angiogenesis.

CTRP3 is a novel member of this family with multiple biological functions (Peterson et al. 2010). It is detected in many tissues and organs, including the heart, liver, adipocytes, cartilage, blood vessels, monocytes, fibroblasts, colon, small intestine, pancreas, kidney, and brain (Schaffler and Buechler 2012).

CTRP3 is considered a strong proangiogenic and neuroprotective adipokine. CTRP3 attenuated secondary brain injury after intracranial hemorrhage (ICH) in rats; it decreased brain edema, preserved the blood-brain barrier (BBB), reduced neurological deficit and encouraged focal angiogenesis. It applies its protective role mainly via an AMPK/HIF-1 $\alpha$ / VEGF-signaling pathway (Wang et al. 2016). CTRP3 also exerts its protective effect during ICH by inhibiting oxidative stress via PKA/NADPH signaling (Yang et al. 2017).

But, the relation between CTRP3 and ASD is not known yet. Whether CTRP3, which is an important member of the recently discovered adipokine family, act as a promotor or inhibitor of ASD has not been studied before. Therefore,

the goal of this work was to measure the level of CTRP3 in autistic children and compare them with peers without ASD.

## Material and Methods

### Study Population

This case-control study was conducted on 32 children with a diagnosis of ASD according to the 5th edition of the diagnostic and statistical manual of mental disorders criteria (American Psychiatric Association 2013). Patients recruited from the Autism Research and Treatment Centre, Department of Physiology, King Saud University, Riyadh, Saudi Arabia. The autistic group composed of 32 males. Their ages ranged between 3 and 12 years (mean  $\pm$  SD =  $7.98 \pm 2.59$  years). Patients who were associated with neurological disease (such as palsy and tuberous sclerosis), metabolic disorders (e.g., phenylketonuria, diabetes), and autoimmune disease were excluded from the study, as metabolic disorders and autoimmunity may influence the results of plasma CTRP3 levels.

The control group formed of 37 age- and sex-matched healthy children, they were collected as previously described by Mustafa and Al-Ayadhi., 2015. Their ages ranged between 3 and 12 years (mean  $\pm$  SD =  $7.83 \pm 2.64$  years). They were not related to the children with ASD, and had no clinical findings indicative of immunological, diabetic, chronic diseases or neuropsychiatric disorders. The control group was the healthy older brothers of the healthy children who visit the Well Baby Clinic, King Khalid University Hospital, Faculty of Medicine, King Saud University, Riyadh, Saudi Arabia for their regular growth assessment (Mustafa and Al-Ayadhi., 2015).

This study received approval from the Ethical Committee of King Khalid University Hospital (E-10-220). An informed written consent was signed by the parents or the legal guardians prior to inclusion in the study.

### Study Measurements:

#### Clinical evaluation of autistic patients:

Clinical evaluation depends on history taken from caregivers, clinical examination and neuropsychiatric evaluation. Childhood Autism Rating Scale (CARS) was used to assess the severity of the disease (Mick 2005). This scale rates the child from one to four in each of fifteen areas (relating to people; emotional response; imitation; body use; object use; listening response; fear or nervousness; verbal communication; non-verbal communication; activity level; level

and consistency of intellectual response; adaptation to change; visual response; taste, smell and touch response and general impressions)(Ozonoff, et al., 2005). According to the scale, children who have scored 30–36 have mild to moderate ASD (n=9), while those with scores ranging between 37 and 60 points have a severe degree of ASD (n=21) (Schopler et al., 1988).

**Blood sample collection.** Ten ml of blood sample was collected in anticoagulant (EDTA) tubes from all the participants after overnight fasting as was previously described by Qasem et al (2016). Plasma and RBCs were collected after centrifugation at 1000 rpm and stored at specific temperatures till used for analysis.

**Assessment of plasma CTRP3 level.** Levels of trimeric CTRP3 (<100 kDa) were measured by BioVendor human CTRP3 ELISA according to manufacturer's protocol, with an intra-assay coefficient of variation of less than 10%. Samples with CTRP3 levels below the detection limit of the assay were assigned the lowest detectable value (0.001 µg/ml). To increase accuracy, all samples were investigated as duplicate independent assays to avoid inter-assay variations and to guarantee reproducibility of the obtained results ( $P > 0.05$ ).

**Statistical analysis.** A software program was used for the statistical analysis, and results were expressed as mean  $\pm$  S.D. All statistical comparisons were made by independent Student's t-test, with P value < 0.05 considered significant. A Wilcoxon-Mann Whitney test usually used when data were not normally distributed (Shapiro-Wilk's test negative). The relationship between the CTRP3, CARs, and age was calculated using the Spearman correlations test, and positive or negative correlations are listed. The receiver operating characteristics (ROC) analysis was performed as an excellent statistical tool for the assessment of the effectiveness of biomarkers; it was done using the same computer software. The area under the curve (AUC) was calculated to find how a plasmatic marker can discriminate between ASD patients and healthy control participants.

## Results:

### Demographic data:

The demographic characteristics of children with ASD and their matched controls are shown in Table 1. Among the ASD patients, 9/30 were mild-moderate, and 21/30 were severe.

**Levels of CTRP3 in total and subgroups of ASD patients compared to neurotypical healthy controls:**

The Shapiro test and boxplot showed that the CTRP3 data in children with ASD and healthy controls were not normally distributed, with P values of 0.03 and 0.005, respectively (Table 2). Tables 3 and 4 together with Figure 1 demonstrate the significant increase in CTRP3 in the plasma of children with ASD compared to age- and sex-matched controls. ASD patients recorded 24% higher CTRP3 plasma levels than healthy controls ( $P < 0.05$ ), while there was no significant difference between mild-moderate and severe autistic children ( $P < 0.127$ ), despite the 38% recorded increase, as shown in Table 4. Boxplots (Figure 1) shows data distribution in control, total ASD, mild-moderate, and severe ASD patients. CTRP3 level, the standard deviation, and the box length as measure of data dispersion of the ASD patients are considerably higher than control healthy participants, and of the severe compared to mild-moderate patients.

**Spearman correlations between CTRP3, age, and CARS:**

Table 5 and Figure 2 present the Spearman correlations among CTRP3, age, and CARS. Whereas this marker did not show any independent correlations with age and CARS ( $P < 0.092$  and  $0.750$ , respectively), both variables (age and CARS) were negatively correlated ( $P < 0.044$ ). The partial correlation between CTRP3 and the CARS while controlling for age was not significant, with a correlation co-efficient of  $-0.210$  ( $p = 0.361$ ).

**Data from ROC analysis:**

Table 6 demonstrates the AUCs, specificity, and sensitivity of all ASD patients as well as the mild-moderate and severe subgroups compared to control subjects and severe autistic patients compared to mild-to-moderate participants. Based on the fact that an AUC of  $0.9-1.0$  shows an excellent predictive value of a biomarker,  $0.8-0.9$  means a very good marker,  $0.6-0.7$  means a satisfactory marker, and  $0.6$  means a useless marker, the AUC of all patients compared to controls (AUC of  $0.636$ ) and that of severe autistic patients compared to controls (AUC of  $0.659$ ) are low but within the satisfactory value (AUC of  $0.6-0.7$ ).

Discussion;

C1q TNF related protein 3 (CTRP3) is a relatively novel hormonal factor primarily derived from adipose tissue and plays a role in early childhood development (Kown et al. 2018). In the present study, the remarkable higher level of CTRP3 in plasma of autistic patients compared to healthy and gender matching controls can be easily related to the disruption of BBB as phenotypic feature in ASD. As a TNF-related protein the increase of CTRP3 is in good agreement with multiple studies in which TNF- $\alpha$  was significantly increased in blood and positively correlated with severity of ASD (Xie et al. 2017).

In addition, Jyonouchi and collaborators (2001) found that TNF- $\alpha$  was elevated in the autistic subjects, and majority of those autistic children exhibited excessive or poorly regulated innate immune responses. Moreover, Chez et al. (2007) found increased TNF- $\alpha$  in the cerebrospinal fluid of autistic children, and it was also significantly increased in the brains of autistic subjects (Li et al. 2009). Although TNF- $\alpha$  was decreased in Saudi autistic patients compared to peers without ASD, this was attributed to the early increase in plasma followed by efflux to the brain through the BBB (El-Ansary and Al-Ayadhi 2014). It is well known that, binding with ligand, TNF- $\alpha$  can activate NF- $\kappa$ B, MAPK, and the apoptosis signaling pathway (Perry et al. 2001). Based on this the significant increase of CTRP3 in the present study can be easily related to the impaired NF- $\kappa$ B, MAPK, and activated apoptosis signaling pathway repeatedly recorded in autistics compared to peers without ASD (Young et al. 2011, 2012; Naik et al. 2011). A study done by Qasem et al. (2018) reported a significant increase of NF- $\kappa$ B in plasma of Saudi patients with autism. Xu et al. (2015) suggest that TNF- $\alpha$  might affect the progress of ASD through another pathway, such as the MAPK/JNK pathway which can be related to the increase of related CTRP3 reported in the present study. Gomez-Fernandez et al (2018) showed that there is no significant difference in the level of the expression of relevant plasma cytokines, cell adhesion molecules or growth factors in children with ASD compared with peers without ASD.

CTRP 3 is definitely induced during late stage of adipocyte differentiation and triggers secretion of adiponectin with certain regulatory metabolic functions (Yi et al. 2012). Current data proves that CTRP3 is functionally the most similar homolog of adiponectin (Schaffler and Buechler 2012) and intravenously injected CTRP3 can cross the BBB and increase the adiponectin levels in the cerebrospinal fluid (Wang and Scherer 2016). Recently, it was found that total CTRP3 concentrations were significantly positively correlated with total cholesterol and HDL cholesterol in children aged 7–10 years (Alamian et al., 2020). Based on this finding, the reported increased level of CTRP3 in autistic patients (Table 3 and 4) could help to support the association between CTRP3 and metabolic diseases and could find support in the recent multidimensional precision medicine approach, which identifies subgroups of individuals with ASD characterized by dyslipidemia (Luo et al., 2020; Josiane da et al., 2021).

Protein kinases are essential in G-protein-coupled, receptor-mediated signal transduction and are involved in neuronal functions, gene expression, memory, and cell differentiation. The cAMP–PKA pathway is one of the most common signaling pathway (Castro et al. 2013). The activity and expression of protein kinase A (PKA), a cyclic AMP–dependent protein kinase, in different areas of postmortem brain of individuals with ASD demonstrated significantly lower level of PKA compared to healthy control subjects. PKA signaling can counteract superoxide anion accumulation and prevent SOD and catalase inhibition induced by oxidative stress in cultured astrocytes (Douiiri et al. 2016). Based on the fact that Saudi autistic children are under H<sub>2</sub>O<sub>2</sub> oxidative stress due to overexpression of SOD with slightly lower catalase, cAMP-PKA can be given special attention (Al-Gadani et al. 2009). PKA signaling mediates CTRP 3's anti-oxidative effects during brain injury have yet to be understood. PKA is involved in CTRP 3 -mediated suppression of ROS in endothelial cells (Goldstein et al. 2009), Yang et al. (2017) confirmed a role for PKA in the protective effects of CTRP 3's against brain injury. It is commonly known that the BBB plays an essential role in the protection of the brain by limiting the influx of circulating harmful solutes, macromolecules, and cells from the blood into the brain. However, numerous studies have revealed that dysfunction of the BBB is associated with the pathogenesis of neurological disorders, including ASD, suggesting that some ASD-related proteins might be secreted from the brain into the blood as potential biomarkers. (Theoharides and Doyle, 2008; Theoharides et al., 2008; Theoharides and Zhang, 2011; Fiorentino et al., 2016).

Based on this the remarkable increase of plasma CTRP3 in the present study can be related to BBB disruption and to brain oxidative stress as confirmed etiological mechanism in ASD. With a disrupted BBB as autistic feature, the recorded increase of CTRP3 could be concomitant with remarkable decrease in the brain due to efflux from brain to blood. A study of Rai-Bhogal et al. (2018) confirmed the inhibition of PKA signaling as a pre-requisite of CTRP3

protective effects with prostaglandins as pro-inflammatory lipid mediator. Prostaglandins were among the elevated lipid mediators previously reported by El-Ansary and Al-Ayadhi (2012) in plasma of Saudi autistic patients compared to peers without ASD. In a most recent study done by Qasem et al. (2018) PGE2 and mPGES-1 were positively correlated with NF- $\kappa$ B as proinflammatory marker and associated with the dysfunction in sensory processing.

Table 6 demonstrates the AUCs, specificity, and sensitivity of all ASD patients compared to control subjects and severe autistic patients compared to mild-to-moderate participants. The recorded AUC of all patients compared to controls (AUC of 0.636) and that of severe autistic patients compared to controls (AUC of 0.659) are low but within the satisfactory value known for ROC AUC (AUC of 0.6–0.7). This could help to accept CTRP3 as a novel predictive biomarker of ASD.

# Conclusion:

CTRP3 is a novel biomarker never measured in plasma of patients with ASD, CTRP3 was higher in autistic patients compared to controls. Therefore, can have a role in the early diagnosis of this disorder.

The data of the current study are hindered by the relatively small sample number of participants, and will, therefore, need to be replicated by larger size of both individuals with ASD and controls. Also, all the recruited subjects in this study were males, so the conclusions cannot be anticipated to be present in females with ASD. The inclusion of both sexes in our future studies may help to clarify the sex differences in this disorder.

**Table 1** (on next page)

*Demographic of children with autism and healthy control*

**Table 1 : *Demographic of children with autism and healthy control***

		Children with autism (n= 32 )	Control group (n=37 )
Age (in years)	Range	3-12	3-12
	Mean $\pm$ SD	7.98 $\pm$ 2.59	7.83 $\pm$ 2.64
Sex	Male	32 males	37 males
CARS scores	Mild to moderate (30–36)	9	-----
	Severe (37–60)	21	-----

# **Table 2**(on next page)

Table\_2\_CTRP3

**Table 2: Test of Normality using Shapiro Test.**

Parameters	Groups	N	P value
CTRP3 (ug/ml)	Control	37	0.005
	Patients	32	0.033
CTRP3 (ug/ ml)	Mild to Moderate	8	0.041
	Severe	20	0.153
Age ( Years)	Mild to Moderate	5	0.037
	Severe	15	0.269

If P value less than or equal to 0.05 then the data is not normal distributed and If P value more than 0.05 then the data is normal distributed

# **Table 3**(on next page)

*Mean  $\pm$  S.D. of CTRP3 in plasma of total autistic patients compared to control subjects.*

Table 3: *Mean  $\pm$  S.D. of CTRP3 in plasma of total autistic patients compared to control subjects.*

Groups	N	Min.	Max.	Mean $\pm$ S.D.	Percent Change	P value
Control (ug/ml)	37	0.12	0.68	0.33 $\pm$ 0.14	100.00	0.050
Patients (ug/ml)	32	0.13	0.99	0.41 $\pm$ 0.18	124.71	

\*Comparing between groups using Mann-Whitney test

**Table 4**(on next page)

*Mean  $\pm$  S.D. of CTRP3 in plasma of Mild to Moderate and Severe autistic patients.*

Table 4: *Mean  $\pm$  S.D. of CTRP3 (ug/ml) in plasma of Mild to Moderate and Severe autistic patients.*

Groups	N	Min.	Max.	Mean $\pm$ S.D.	Percent Change	P value
Mild to Moderate	8	0.20	0.58	0.31 $\pm$ 0.12	100.00	0.127
Severe	20	0.13	0.99	0.43 $\pm$ 0.20	138.16	

**Table 5**(on next page)

*Spearman correlations between CTRP3, CARs,*

Table 5: *Spearman correlations between CTRP3, CARs,*

Parameters	R (Spearman Correlation)	P value	
CTRP3 with Age	-0.368	0.092	N <sup>b</sup>
CTRP3 with CARS	0.061	0.750	P <sup>a</sup>
Age with CARS	-0.433*	0.044	N <sup>b</sup>

- \* Correlation is significant at the 0.05 level.
- <sup>a</sup> Positive Correlation.
- <sup>b</sup> Negative Correlation.

**Table 6**(on next page)

*ROC-Curve of CTRP3 in all patients Group according to Control Group*

**Table 6: ROC-Curve of CTRP3 in all patients Group according to Control Group**

CTRP3 ROC	AUC	Cut-off value	Sensitivity %	Specificity %	P value	95% CI
All patients according to Control	0.636	0.341	56.2 %	70.3 %	0.050	0.503 - 0.769
Mild to Moderate according to Control	0.532	0.315	75.0 %	43.2 %	0.778	0.326 - 0.738
Severe according to Control	0.659	0.341	65.0 %	70.3 %	0.049	0.504 - 0.814
Severe according to Mild to Moderate	0.688	0.372	60.0 %	87.5 %	0.127	0.479 - 0.896

# Figure 1

boxplot to show the data distribution of CTRP3 in the control and patients' groups (a), and data distribution of CTRP3 in mild to moderate and sever autistic groups (b).

# Figure 2

Correlation between CARS and Age with best fit line curve (negative correlation)
