Background. African elephants in managed care have presented differences in the balance between omega-3 and omega-6 fatty acids, a situation primarily thought to be due to dietary differences between the managed animals and their free-ranging counterparts. Because of this, circulating fatty acid status is included in routine monitoring of elephant health. A method of blood collection that requires only a few drops of whole blood, dried on filter paper (DBS) and can be used for analyzing full fatty acid profiles offers advantages in clinical application.

Methods. This study compared the use of whole blood, and whole blood DBS, serum or plasma for use in evaluating circulating fatty acid composition in African savannah elephants. Samples from 6 African elephants (two males and four females) were collected during the same week at the NC Zoo, Asheboro, NC.

Results. Results found only 2 of 36 individual fatty acids and none of the 10 fatty acid groupings were different when comparing the four blood fraction sample types to each other with Mann-Whitney U-Test pairwise comparisons. Myristic acid (14:0) was lower in the DBS samples than in whole blood, serum, and plasma and pentadecaenoic acid (15:1) was slightly more concentrated in DBS and whole blood.

Discussion. Results indicate that fatty acid profile of serum, plasma, whole blood, and DBS are comparable in African elephants. The DBS method offers advantages in acquisition and handling and may be preferable to other methods in both routine health assessment of captive animals and field research on free ranging animals.

20 **Abstract**
21 **Background.** African elephants in managed care have presented differences in the balance
22 between omega-3 and omega-6 fatty acids, a situation primarily thought to be due to dietary
23 differences between the managed animals and their free-ranging counterparts. Because of this,
24 circulating fatty acid status is included in routine monitoring of elephant health. A method of
25 blood collection that requires only a few drops of whole blood, dried on filter paper (DBS) and
26 can be used for analyzing full fatty acid profiles offers advantages in clinical application.
27 **Methods.** This study compared the use of whole blood, and whole blood DBS, serum or plasma
28 for use in evaluating circulating fatty acid composition in African savannah elephants. Samples
29 from 6 African elephants (two males and four females) were collected during the same week at
30 the NC Zoo, Asheboro, NC.
31 **Results.** Results found only 2 of 36 individual fatty acids and none of the 10 fatty acid groupings
32 were different when comparing the four blood fraction sample types to each other with Mann-
33 Whitney U-Test pairwise comparisons. Myristic acid (14:0) was lower in the DBS samples than
34 in whole blood, serum, and plasma and pentadecaenoic acid (15:1) was slightly more
35 concentrated in DBS and whole blood.
36 **Discussion.** Results indicate that fatty acid profile of serum, plasma, whole blood, and DBS are
37 comparable in African elephants. The DBS method offers advantages in acquisition and handling
38 and may be preferable to other methods in both routine health assessment of captive animals and
39 field research on free ranging animals.
40

41 **Introduction**
42 The optimal management and conservation of African savanna elephants (*Loxodonta africana*)
43 in both free-ranging and managed environments requires better understanding of their metabolic

44 and nutritional status. Free fatty acids, and the triglycerides they form, are critical for the health
45 and function of a variety of body systems and are also biomarkers for many health concerns
46 (Nagy and Tiuca, 2017). The importance of fatty acids includes cell membrane integrity and the
47 production of energy for the body as well as impacts on inflammatory processes, cardiovascular,
48 liver, pancreas, and retina health (Connor, 2000, Figueiredo et al., 2017, Nagy and Tiuca, 2017).
49 Studies primarily in rodents have shown Omega-3 fatty acids lower inflammatory responses,
50 reduce the risk of atherosclerosis, and improve pancreatic function by reducing insulin resistance
51 and increase reproductive success (Connor, 2000, Figueiredo et al., 2017, Fritsche, 2006, Nagy
52 and Tiuca, 2017). While understudied in other species, correlations between dietary omega-3 and
53 omega-6 imbalances and atherosclerosis have been noted in several species, including African
54 elephants (McCullagh, 1972). Additionally, studies have found differences in circulating fatty
55 acids when comparing free ranging versus managed animals for several species (Clauss et al.,
56 2008, Clauss et al., 2007, Dass et al., 2020 & 2021; Schmidt et al., 2009).
57
58 Most data available on African elephant free fatty acids is only available from serum or plasma
59 samples (Clauss et al., 2003, McCullagh, 1973, Moore and Sikes, 1967, Wood et al., 2020).
60 Plasma and serum have been considered to better reflect the short-term circulating fatty acid
61 status of animals while whole blood is thought to provide more information on the overall fatty
62 acid status (Baylin et al., 2005, Hodson et al., 2013, Risé et al., 2007, Thomas Brenna et al.,
63 2018). With differing opinions on the best blood fraction to collect for fatty acid analysis and
64 concerns about sample collection, handling, and storage, researchers have begun to look to new
65 blood collection methods for further answers.
66
67 Alternative methods of fatty acids analysis have been successfully used to analyze human blood
68 with a few drops of dried whole blood on filter paper cards (Armstrong, et al., 2008, Bailey-Hall,
69 et al., 2008). These only require small volumes of whole blood to run full free fatty acid profiles
70 and are more easily collected and stored in field research settings (Freeman et al., 2018). Because
71 of this positive impact on field research, DBS cards have become more prevalent in wildlife
72 research, but direct comparisons to serum, plasma, or liquid whole blood for a majority of
73 species is lacking (Koutsos et al., 2021, Dass et al., 2020 & 2021). This has led to the research
74 question of how comparable DBS samples compare to more traditional samples such as liquid
75 whole blood, serum, or plasma regarding fatty acid profiling.
76
77 The goal of this research was to: compare the results of fatty acid analysis of DBS samples to a)
78 traditionally collected whole blood, b) serum, and c) plasma of a cohort of managed elephants
79 maintained on a known diet.
80
81 **Materials & Methods**
82 Animals and Diets
83 Six adult African elephants (2 males and 4 females) managed at the North Carolina (NC) Zoo,
84 Asheboro, NC, USA were sampled between 8:30 and 9:30 AM within one week during July
85 2020. This study was approved by the NC Zoo Animal Research Committee. These animals were
86 fed a diet of Mazuri® Hay Enhancer™, fresh cut browse, timothy hay, and daytime pasture
87 access for grazing.
88
89 Sample Collection and Analyses

90   Blood samples were taken under veterinary supervision via auricular veins during routine
91   monthly wellness exams. Blood was placed into 1) untreated red top vacutainer tubes, 2) lithium
92   heparin green top vacutainer tubes, 3) serum separator red and black top vacutainer tubes, and 4)
93   plasma separator tubes with lithium heparin light green top vacutainer tubes (Becton, Dickinson
94   and Company, Franklin Lakes, NJ, USA). All elephants were trained with positive reinforcement
95   for regular blood collections, so restraints were not used. Previous serum samples collected and
96   analyzed for fatty acids in 2016-2017 by Wood et al (2020) were not included in the current
97   study and serum samples collected in this study are new and are not part of the work published in
98   2020. Whole blood collected in the untreated vacutainers were transferred to Perkin-Elmer Spot
99   Saver cards (Perkin-Elmer, Waltham, MA, USA) using four spots of approximately 80 μL of
100 whole blood (approximately 320 μL per card). Samples collected in serum and plasma separator
101 tubes were centrifuged and transferred to cryovials. Cryovials of whole blood, plasma, and serum
102 as well as dried blood spot (DBS) cards were frozen at -80℃ within 3 hours of collection and
103 stored for approximately 2 months before being shipped on dry ice to Lipid Technologies
104 (Austin, MN, USA) for a simultaneous full fatty acid profile analysis including 36 individual
105 fatty acids and 10 fatty acid groups (Table 1). Using established methods, samples were
106 transmethylated with acidified methanol and the fatty acid methyl esters were quantified by area
107 percent as analyzed on routine gas chromatography (https://lipidlab.com/services/; Koutsos et al.,
108 2021). Values are provided on a percent of total fatty acids present.
109
110
111 Statistics
112 Statistical analysis was conducted to compare DBS, whole blood, serum, and plasma to each
113 other using pairwise comparisons by the Mann-Whitney U-test with an α = 0.05 and a U test
114 statistic of 5. Pairwise comparisons included 1) DBS compared to whole blood (U-statistic = 5),
115 2) DBS compared to serum (U-statistic = 5), 3) DBS compared to plasma (U-statistic = 5), 4)
116 whole blood compared to serum (U-statistic = 5), 5) whole blood compared to plasma (U-
117 statistic = 5), and 6) serum compared to plasma (U-statistic = 5). Because the sample size was
118 small (n=6) and the use of nonparametric statistics, p-values are not provided in this article
119 because this method of statistical analysis leads to p-values that are inaccurate and do not
120 provide valuable information. Instead of p-values, the Mann-Whitney U-test uses a critical value
121 U-statistic for comparison, when the calculated value is less than or equal to the critical value U-
122 statistic then we fail to reject the null hypothesis and there are no differences.
123
124
125 **Results**
126 Of the 36 individual fatty acids and 10 fatty acids groups identified, 30 individual and 10 fatty
127 acid groups were quantifiable (Table 1). The six fatty acids that were not present in sufficient
128 quantity to be reliably quantified within any of the blood sample types were lauric acid (12:0), 9-
129 hexadecenoic acid (16:1w5), margaric acid (17:0), heptadecenoic acid (17:1), vaccenic acid
130 (18:1w7), and 13-octadecenoic acid (18:1w5).
131
132 Pairwise comparisons of DBS and whole blood, DBS and serum, DBS and plasma, whole blood
133 and serum, whole blood and plasma, and serum and plasma using the Mann-Whitney U-Test,
134 found differences between sample type only for myristic acid (14:0) and pentadecaenoic acid
135 (15:1). Data for myristic acid (14:0) initially showed a lower concentration present in the DBS

136 samples than in whole blood, serum, and plasma with a very large variability. This was
137 apparently due to one sample which was an obvious outlier. When statistics were run excluding
138 this outlier DBS card data for myristic acid was tighter but much lower than identified with any
139 on the other types of blood samples. The differences identified for pentadecaenoic acid (15:1)
140 concentrations were complicated by variability among the whole blood results and serum results.
141 These variations were much greater than seen for plasma and particularly for DBS sample results
142 (Table 1). No notable differences between data from frozen whole blood samples were seen
143 when comparing the animals by age (approximately ages 14 to 48 years) or sex.
144
145 **Discussion**
146 Results of this study found DBS to be an acceptable method when compared to the analysis of
147 other blood fractions examined for both individual fatty acids and fatty acid groups with the
148 possible exception of the fatty acids, myristic and pentadecaenoic acid. This finding is consistent
149 with studies on human blood that have found that DBS is a useful and comparable collection
150 method for fatty acids (Armstrong et al., 2008, Bailey-Hall et al., 2008, Thomas Brenna, et al.,
151 2018). Visual differences of interest included the lack of myristoleic acid (14:1) and pentadecylic
152 acid (15:0) found in the DBS samples. Myristoleic acid concentrations were very low across all
153 sample types and only a few were detectable above baseline. It is possible that differences seen
154 between sample types was due to residue from the filter paper or external contamination, but
155 more likely the low concentrations present were below reliable detection limits considering the
156 expected error in sample extraction methods. The statistically significant differences for myristic
157 acid and pentadecanoic acid (15:1) are hypothesized have been related to challenges with elution
158 from the DBS card.
159
160 Values found in this study were similar to previous samples collected and analyzed by the
161 authors with the same six African elephants (Wood et al., 2020). These values were also
162 comparable to serum and plasma values collected in free-ranging elephants (Clauss et al., 2003,
163 McCullagh, 1973, Moore and Sikes, 1967).
164
165 Results from this study were favorable for cross comparisons of important individual fatty acids
166 and fatty acid groups including traditional essential fatty acids: α-linolenic acid, linoleic acid,
167 critical fatty acids: eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), and
168 important fatty acid groups: omega-3 fatty acids, polyunsaturated fatty acids (PUFAs), and the
169 omega-6 : omega-3 ratio. As mentioned in the introduction, in managed settings, it has been
170 noted that herbivores often have higher levels of omega-6 fatty acids in their diet and circulation
171 leading to an inappropriate omega-6 : omega-3 ratio when compared to free-ranging animals
172 (Clauss et al., 2003, Clauss et al., 2007). This could be relevant to problems with obesity in
173 elephants in managed care (Morfeld et al., 2016). Being able to track circulating omega-3 fatty
174 acids, especially EPA and DHA in elephants and potentially other megavertebrates using the
175 simpler DBS collection of a few drops of blood would greatly facilitate better monitoring across
176 institutions.
177
178 **Conclusions**
179 Data provided in this study supports the hypothesis that fatty acid composition of whole blood,
180 plasma, and serum are very similar in African savanna elephants. Fatty acid results from DBS

181 samples provide a reasonably comparable approach to liquid whole blood samples, which are
182 more difficult to store and ship.

Fatty Acid Groups	Average (SD)	Average (SD)	Average (SD)	Average (SD)
Saturates	30.5 (1.83)	40.4 (1.45)	31.4 (3.02)	30.7 (2.14)
Monoenes	25.0 (2.42)	30.5 (2.13)	20.1 (3.29)	21.0 (4.17)
Poly unsaturated fatty acids (PUFA)	41.0 (3.20)	25.3 (3.13)	45.6 (6.70)	45.2 (6.73)
Highly unsaturated fatty acids (HUFA)	17.6 (2.74)	9.7 (2.21)	17.8 (4.72)	17.7 (3.99)
Total w3 fatty acids	8.3 (1.00)	4.5 (0.81)	9.0 (1.51)	8.4 (0.91)
Total w6 fatty acid	32.7 (2.83)	20.7 (2.84)	36.6 (5.98)	36.8 (6.20)
Total w9 fatty acids	23.4 (2.41)	29.3 (2.27)	19.3 (3.08)	20.3 (3.98)
w6/w3 fatty acid ratio	4.0 (0.51)	4.7 (0.90)	4.1 (0.74)	4.4 (0.64)
Omega 3 HUFA	25.6 (3.73)	26.8 (4.27)	26.8 (4.67)	25.9 (3.76)
Omega 6 HUFA	74.4 (3.73)	73.2 (4.27)	73.2 (4.67)	74.2 (3.76)

[1] Fatty acids that were not in high enough concentration to be quantified included: lauric acid (12:0), 9-hexadecenoic acid (16:1w5), margaric acid (17:0), heptadecenoic acid (17:1), vaccenic acid (18:1w7), and 13-octadecenoic acid (18:1w5).

[2] Differing superscripts ([a,b]) in averages columns are significantly different at ($\alpha = 0.05$, U-statistic = 5) for DBS compared to plasma

[3] Differing superscripts ([x,y]) in averages columns are significantly different at ($\alpha = 0.05$, U-statistic = 5) for DBS compared to whole blood

[4] Differing superscripts ([¶,‡]) in averages columns are significantly different at ($\alpha = 0.05$, U-statistic = 5) for DBS compared to serum

[5] Differing superscripts ([§,□]) in averages columns are significantly different at ($\alpha = 0.05$, U-statistic = 5) for plasma compared to whole blood

[6] Differing superscripts ([¥,£]) in averages columns are significantly different at ($\alpha = 0.05$, U-statistic = 5) for serum compared to whole blood

[7] Outlier from DBS samples was removed for mean and SD calculations thus DBS n=5 (U-statistic = 3)
