Abstract

The C2H2-type zinc finger proteins (C2H2-ZFPs) have been reported regulating various developmental processes or abiotic stresses response in eukaryotes. However, there is no comprehensive analysis of these transcription factors in *P. ostreatus*. Identification and characterization of these proteins in *P. ostreatus* could be desired to be found candidate genes to control the development or abiotic tolerance breeding. In this study, 18 *C2H2-ZFs* were identified in *P. ostreatus* genome. The result of phylogenetic analysis indicating these proteins have a low similarity. And, a wide range of variations also displayed among these genes, including the protein characteristics, gene intron-exon structure, and motif composition. Then, the expression patterns of *PoC2H2-ZFs* in mycelia, primordia, young and mature fruiting bodies were investigated by RT-qPCR. Besides, the expressions of some *PoC2H2-ZFs* can be regulated by auxin and cytokinin. And, under heat and cold stresses, members of *PoC2H2-ZFs* expression levels are changed dramatically, suggesting these genes may participate in different abiotic stress responses. The findings of this study will facilitate the study of the *C2H2-ZFs* role in *P. ostreatus* development and stress tolerance.

Keywords: *Pleurotus ostreatus*; C2H2-ZFPs; expression pattern; development; abiotic stress

Introduction

Pleurotus ostreatus is a widely cultivated mushroom for its nutritional value, relatively simple cultivation techniques, and wide sources of cultivation materials(Chang & Miles, 2004; Khan & Taina, 2012). The production of *P. ostreatus* relies on the precise control of fruiting body development. The formation of fruiting bodies starts with two different mating types of hyphae combined and form dikaryotic hyphae, which is called plasmogamy. These dikaryotic hyphae can be aggregated to develop into primordia, which further differentiate into fruiting bodies. Genome sequencing of model mushroom *Schizophyllum commune* indicating many predicted transcription factors like zinc finger proteins (ZFPs), MYB, fungal specific transcription factor

(fst), and so on, are differentially expressed during sexual development (Ohm et al., 2010). In *P. ostreatus*, the *Pofst3* was cloned as homolog gene of *S. commune fst3* and functional analysis has characterized its role during primordia formation (Qi et al., 2019). These results indicating that transcription factors may play an important role in mediating the development of *P. ostreatus*. However, only a few transcription factors have been reported in this commercial mushroom. Therefore, identification and characterization of more transcription factors in *P. ostreatus* can provide the opportunity to identify the interesting proteins importantly in various development processes, which can be desired for breeding to control mushroom development.

ZFPs are one of the largest transcription factor families in eukaryotic genomes (Laity, Lee & Wright, 2001). The term “zinc finger” refers to these proteins harbor a conserved domain, in which consisting of cysteine (C) and/or histidine (H) residues responsible for bonding with a zinc ion comprising a two-stranded antiparallel beta-sheet and a helix (Takatsuji 1998). Based on the number and location of the C and H residues, the ZFPs can be divided into different types: C2H2, C2HC, C2HC5, C2C2, C3H, C3HC4, C4, C4HC3, C6, and C8 (Berg & Shi 1996). Among them, C2H2-type zinc finger proteins (C2H2-ZFPs) are the ones most widely studied. The zinc finger domain in these proteins containing two C and two H residues, which are described as C-X(2-4)-C-X12-H-X(3-5)-H (where X represents any amino acid) (Pabo, Peisach & Grant, 2001).

The C2H2-ZFPs have been widely studied in plants, functional analysis has shown that *C2H2-ZFs* are involved in vegetative growth and reproductive development (An et al., 2012; Lu et al., 2012; Sun et al., 2015). Besides, there also have been demonstrated the role of *C2H2-ZFs* in mediating growth and development in fungi, including hyphal growth (Tian et al., 2017), sexual development (Kim et al., 2009), oospores production (Wang et al., 2009), and so on. Moreover, the *c2h2*-overexpression strains did not affect the normal development in *Agaricus bisporus*, however, the yield per day of the strains peaked 1 day earlier, indicating the impact of *C2H2-ZFs* in mushroom formation (Pelkmans et al., 2016), which makes a target gene for breeding of this commercial mushroom. However, there are no findings conducted about *C2H2-ZFs* roles in *P. ostreatus* development so far.

Apart from participating in regulating various development processes, *C2H2-ZFs* also have been found to play crucial roles in defense to abiotic stress. In plants, they have been shown to respond to heat (Mittler et al., 2006), and functional analysis has shown they are positively improving drought (Yin et al., 2017), cold (Liu et al., 2017), and salt stress (Ciftci-Yilmaz et al., 2007). In China, the traditional greenhouses are mainly used for cultivating *P. ostreatus*, which poorly in environmental conditions control. Environmental stress, especially heat, always threatening the development of mushrooms. The extreme and continuous high temperature can inhibit mycelial growth (Yan et al., 2020), disruption of the cell wall integrity, and enhance the ability of *Trichoderma asperellum* to infect mycelia (Qiu et al., 2018), then reduce the yield of mushrooms. Therefore, identification of *C2H2-ZFs* in *P. ostreatus* also can be desired to find candidate transcription factors for breeding to improve the ability to defend against environmental stress.

Therefore, the *C2H2-ZFs* in *P. ostreatus* genome were identified and characterized by bioinformatic analysis in this study. Then, the expression profiles of them in different tissues were analyzed in order better understand their potential roles in regulating *P. ostreatus*

development. Besides, we also analyzed their expression pattern under environmental stress. The results of the work would add useful information about the characterization of *C2H2-ZFs* in mushrooms, and also providing with gene sources for control the development and abiotic tolerance breeding in *P. ostreatus*.

Materials & Methods

Identification and characteristics of C2H2-ZFPs in *P. ostreatus*

First, the Hidden Markov Model (HMM) profile of the C2H2 domain sequences (PF00096) was downloaded from the Pfam database and used as a query in the HMMER3.0 program against the publicly available genome database of *P. ostreatus* which download from JGI (http://genome.jgi.doe.gov/PleosPC15_2/) to search for C2H2-ZFPs with an *E*-value less than $1e^{-4}$. Then, the candidate C2H2-ZFPs were submitted to SMART (<http://smart.embl-heidelberg.de>) to confirm the presence of the C2H2 domain. Furthermore, the C2H2 domain without the expression of “C-X₍₂₋₄₎-C-X₁₂-H-X₍₃₋₅₎-H” in protein were deleted by manual, and the rest were regarded as PoC2H2-ZFPs. The subcellular localizations of PoC2H2-ZFPs were predicted in WoLF PSORT (<http://wolfsort.org/>), and the ExPasy site (<http://web.expasy.org/protparam/>) was used to calculate the molecular weight (MW) and isoelectric point (pI).

Phylogenetic analysis and multiple sequences alignment

A phylogenetic tree among C2H2-ZFPs in *P. ostreatus* was constructed using the MEGA-X program (Sudhir et al., 2018) via the neighbor-joining (NJ) method based on the JTT model with bootstrapping was performed 1000 times.

Multiple sequence alignment of the full C2H2-ZFPs and C2H2 domain were performed using MEGA-X and loaded into Jalview software to visualize (Waterhouse et al., 2009).

Gene structure and motif analysis

The exon-intron organization of *C2H2-ZF* genes was obtained from genomic information and drawn using Tbtools (Chen et al., 2020). Then, the proteins were submitted into online MEME (<http://meme-suite.org/tools/meme>) to identify conserved motifs with 5 motif numbers, and the optimum motif length was set with the default parameters (6-50 residues).

Strains, culture conditions, and sample collection

The strains *P. ostreatus* 3125 provided by the Institute of Scientific Edible Fungal, Gaoyou, China, was used for culture and sample collection. The fungi were grown in potato dextrose agar (PDA) medium was transfer to sterility fully-boiled wheat grain medium and cultured at 25 °C in the dark in a temperature-controlled incubator. Then, after 5 days later, put a little wheat grain with mycelium into sterility growth bags, composed of 60% cottonseed hulls, 35% corncob, 10% bran, 3% gypsum, 2% kalk, with 55% humidity, and continued cultured in the temperature-controlled incubator. Waiting for mycelium growth fully in growth bags (Fig. 3a), the mycelium was collected. To obtaining primordia, the growth bags were transferred to the culture room with

the condition was: 10-13 °C, 80% humidity. And the young and mature fruiting bodies were collected while primordia beginning differentiates into fruiting bodies at the 6th and 12th days, respectively (Fig. 3a). All the samples collected were frozen in liquid nitrogen immediately and stored at -80 °C.

Hormones and abiotic stress treatments

The primordia were selected for treatment with hormones and environmental stress to analyze the response of *PoC2H2-ZFs*. For hormones treatment, the primordia were covered with absorbent cotton which was soaked with 200 ul 0.01 mM IAA, 0.01 mM zeatin, and H₂O, respectively. Then, sampled after 1, 3 hours (h). For environmental stress treatment, the primordia were cultured at 38 °C and 4 °C in a temperature-controlled incubator for 1, 3 h, respectively, for heat and cold stress treatment, while cultures at the culture room with the condition: 10-13 °C used as controls.

Isolation of RNA, cDNA synthesis, and RT-qPCR analysis

Total RNA from collected samples were isolated using Plant Total RNA Isolation Kit (Sangon Biotech Co., Ltd, ShangHai). The cDNA was generated using MightyScript First Strand cDNA Synthesis Master Mix (Sangon Biotech Co., Ltd, ShangHai) according to the manufacturer's protocol. In addition, 2X SG Fast qPCR Master Mix (Sangon Biotech Co., Ltd, ShangHai) was used to perform RT-qPCR. The *sar* gene was used as the reference (Castanera et al., 2015) and primer sequences used for RT-qPCR were listed in Table S3. The relative expression level of genes was analyzed using the $2^{-\Delta CT}$ or $2^{-\Delta\Delta CT}$ method. The heatmap of *PoC2H2-ZF* genes was generated using Tbtools (Chen et al., 2020) .

Results

Identification, characterization, and phylogenetic analysis of C2H2-ZFPs in *P. ostreatus*

Based on the HMM results and manual correction, 18 C2H2-ZFPs were identified in the *P. ostreatus* genome. All these proteins contained one to four conserved C2H2 domains where were distributed in the N-terminus or C-terminus (Fig. S1). Detailed information about characteristics of these proteins, like amino acid size, MW, isoelectric points, and so on, were also analyzed (Table S1). The results showed PoC2H2-ZFPs had between 149 and 688 amino acids in polypeptide length, with MW ranging from 16.4 (*PleosPC15_2|1089905*) to 74.8 kDa (*PleosPC15_2|1054163*) and isoelectric points ranging from 4.66 (*PleosPC15_2|1079678*) to 10.8 (*PleosPC15_2|1089905*). According to the results of predicted subcellular localization, all the PoC2H2-ZFPs were predicted as nuclear proteins (Table S1).

To analyze the phylogenetic relationships of these C2H2-ZFPs among *P. ostreatus*, a phylogenetic tree was constructed based on their full protein sequences. As a result, the 18 PoC2H2-ZFPs were clustered into four groups (Fig. 1a). PleosPC15_2|1104202 form a single-branch clade, indicating its independent origin. The bootstrap supports of some main branches were very low. Besides that, most PoC2H2-ZFPs in the same group showed low bootstrap values (<60%). Only PleosPC15_2|1111338 and PleosPC15_2|1095114 had strong bootstrap (100%),

which regard as one sister pairs. The results of sequence alignment indicating the PoC2H2-ZFPs showed low sequence similarity (Fig. S1).

Gene structure and conserved motif analysis of *PoC2H2-ZFs*

To gain insights into the genetic structure of *PoC2H2-ZFs*, the exon-intron organization of them was analyzed. The results showed the diverse gene structures were exhibited in *PoC2H2-ZFs* and also appeared to be more variable in the same group (Fig. 1b). The number of introns varied from 0 to 4 in group I, 1 to 2 in group II, *PleosPC15_2|1104202* showed 5 exons and 4 introns, and in group IV had 1 to 7 introns (Fig. 1b).

To further investigate the diversity of the PoC2H2-ZFPs, the motif composition was analyzed using MEME online server (Fig. 1c). The results identified five putative conserved motifs (while the number was set beyond five, the *E*-value of the motif ($X > 5$) was greater than one. Data was not shown). Motif 1 was predicted encoding the conserved region (C-X₂-C-X₁₂-H-X₃-H) that corresponds to the characteristic motif of C2H2 domain (Table S2), were detected in N-terminus or C-terminus of all PoC2H2-ZFPs (Fig. 1c). And, the motif 3 also represented one type of C2H2 domain (C-X₄-C-X₁₇-H-X₃-H) (Table S2), and the *PleosPC15_2|1046937*, *PleosPC15_2|1079678*, and *PleosPC15_2|1091415* in group I, *PleosPC15_2|1077016*, *PleosPC15_2|1051309*, *PleosPC15_2|1054163*, and *PleosPC15_2|157229* in group IV contained it in sequences (Fig. 1c). Motif 2 was predicted encoding a false motif of the C2H2 domain that lacks a conserved H residue in the C-terminus (Table S2), also showed distributed in 17 PoC2H2-ZFPs (Fig. 1c). From the data, the PoC2H2-ZFPs were showed diverse motif compositions. In group I, *PleosPC15_2|1107157*, *PleosPC15_2|1088285*, and *PleosPC15_2|1089005* containing the motifs 1 and 3, while motifs 1, 2, and 3 were contained in others (Fig. 1c). For group II, the *PleosPC15_2|160383* only had one motif 1 (Fig. 1c). Among them, the *PleosPC15_2|1111338* and *PleosPC15_2|1095114* also containing motifs 4 and 5 in N-terminus and C-terminus, respectively (Fig. 1c). In group IV, the *PleosPC15_2|1102393*, *PleosPC15_2|1095325*, and *PleosPC15_2|1053338* share the same motif composition that containing motifs 1 and 2 in the N-terminal region, and others also containing one motif 3 in the C-terminal region (Fig. 1c).

Conserved domain analysis of the PoC2H2-ZFPs

To investigate the characteristics of C2H2 domains in *P. ostreatus*, multiple sequence alignment was performed to analyze conservative amino acids in the C2H2 domain. The result revealed there were 23-26 amino acids in 29 predicted C2H2 domains (Fig. 2a). The variation of sequence length was due to the amino acid numbers changed in C-X₍₂₋₄₎-C and H-X₍₃₋₅₎-H region. Among them, 15 C2H domains contained two amino acids in the C-X₍₂₋₄₎-C region while others contained four amino acids (Fig. 2a). 24 C2H2 domains contained three amino acids, 3 contained four amino acids, and 2 contained five amino acids in the H-X₍₃₋₅₎-H region (Fig. 2a). Two C and H residues were conserved in domains. Besides that, the F and L residues also showed the most conservative (Fig. 2a). The signature sequences of C-X₍₂₋₄₎-CX₃FX₅LX₂H₍₃₋₅₎H in C2H2 domains was corresponding to the conserved amino acid analysis of motif 1 (Fig. 2b), suggesting this feature motif was conserved in PoC2H2-ZFPs.

Expression analysis of *PoC2H2*-ZFs during different developmental stages

To investigate the expression profiles of the *PoC2H2*-ZFs during different developmental stages, a heatmap was displayed based on the RT-qPCR result by analyzing their expression patterns at four different tissues (mycelia, primordia, young fruiting body, and mature fruiting body) (Fig. 3a). The result showed *PoC2H2*-ZFs had distinct spatial and temporal expression patterns. All of the *PoC2H2*-ZFs had a continuous expression in four different tissues (Fig. 3b). The *PeosPC15_2|1046937*, *PeosPC15_2|1107157*, *PeosPC15_2|1102653*, *PeosPC15_2|1077016*, and *PeosPC15_2|1053338* were showed lowest expression level in four tissues (Fig. 3b). Besides that, most *PoC2H2*-ZFs expression is relatively higher in mycelia, primordia, and young fruiting body, but lower in the mature fruiting body (Fig. 3b). The *PeosPC15_2|1077016*, *PeosPC15_2|112393*, and *PeosPC15_2|1088285* had high expression in mycelia. Five genes (*PeosPC15_2|1079678*, *PeosPC15_2|1089905*, *PeosPC15_2|1111338*, *PeosPC15_2|1095114*, and *PeosPC15_2|1095325*) exhibited the increased expression from the mycelia to primordia (Fig. 3b). The expression level of all *PoC2H2*-ZFs was increased when the primordia differentiate into the fruiting body (Fig. 3b). While the fruiting body turning to ripen, most of the *PoC2H2*-ZFs decrease the expression, only the expression of three genes (*PeosPC15_2|1088285*, *PeosPC15_2|1089905*, and *PeosPC15_2|1102653*) increased continuously (Fig. 3b).

Expression analysis of *PoC2H2*-ZFs response to auxin and cytokinin

To study the response of *PoC2H2*-ZFs under hormones, the primordia was treatment with IAA and zeatin for 1 h and 3 h, respectively. Twelve genes were selected to study their expression profiles, and in our results, only the expression of *PeosPC15_2|1046937* was not affected treatment with auxin or cytokinin, other members were showed regulated by the hormones (Fig. 4). Like *PeosPC15_2|1091415* and *PeosPC15_2|1102653*, their expression was downregulated treatment with zeatin for 1 h, while *PeosPC15_2|1079678* and *PeosPC15_2|1089905* was increased (Fig. 4). In addition, four genes (*PeosPC15_2|1079678*, *PeosPC15_2|1095114*, *PeosPC15_2|1051309*, and *PeosPC15_2|157229*) was upregulated treatment with zeatin after 3 h (Fig. 4). In auxin treatments, the expression of *PeosPC15_2|1079678* was increased after 1 h. Other members, like *PeosPC15_2|1079678*, *PeosPC15_2|1089905*, and *PeosPC15_2|1095114*, were increased after 3 h, while *PeosPC15_2|1102653* was downregulated (Fig. 4). From our data, we can see that *PoC2H2*-ZFs have different expression responses to auxin and cytokinin.

Expression analysis of *PoC2H2*-ZFs under different abiotic stresses

Then, to investigate the potential roles of *PoC2H2*-ZFs in abiotic stress, their expression profiles were analyzed under heat and cold stress. The results showed that the expression of five genes (*PeosPC15_2|1079678*, *PeosPC15_2|1089905*, *PeosPC15_2|1095114*, *PeosPC15_2|1051309*, and *PeosPC15_2|157229*) was upregulated after heat stress treatment with 1 h (Fig. 5). The *PeosPC15_2|1102653* showed downregulated with heat treatment after 3 h, while the expression of *PeosPC15_2|1102653* and *PeosPC15_2|1051309* was increased (Fig. 5). For cold treatments with 3 h, the expression of *PeosPC15_2|1046937* and *PeosPC15_2|1102653* were significantly suppressed, whereas *PeosPC15_2|1111338*, *PeosPC15_2|1051309*, *PeosPC15_2|1089905*, *PeosPC15_2|157229*, and *PeosPC15_2|1104202* was increased (Fig. 5). There are two *PoC2H2*-

ZFs (*PeosPC15_2|1091415* and *PeosPC15_2|1053338*) that showed the expression was not affected after 1, 3 h with cold and heat treatment (Fig. 5). These data suggesting that *PoC2H2-ZFs* have different expression responses to abiotic stresses.

Discussion

The C2H2-ZF proteins as one largest transcription factor that widely existed in the eukaryotic kingdom have been reported to play important roles in mediating plant growth and stress response (An et al., 2012; Ciftci-Yilmaz et al., 2007; Liu et al., 2017; Lu et al., 2012; Sun et al., 2015; Yin et al., 2017). Moreover, there also have been demonstrated the role of *C2H2-ZFs* in fungi growth and development, like hyphal growth (Tian et al., 2017), microsclerotia formation (Tian et al., 2017), sexual development (Kim et al., 2009), and so on. In particular, its effect on changing the yield of *Agaricus bisporus* (Pelkmans et al., 2016), one of the widely cultivated commercial mushrooms, making the *C2H2-ZFs* be important candidate genes for breeding edible mushrooms. *P. ostreatus* is one of the widely cultivated mushrooms in China, however, the study about this important transcription factor is limited in it. In this paper, a systematic analysis of *C2H2-ZFs* was performing in *P. ostreatus*, including phylogenetic relationships, gene structures, conserved motifs, expression patterns during growth and development, and under various hormones and abiotic stress treatments.

In this study, 18 *C2H2-ZFs* were identified in *P. ostreatus* through genome-wide analysis. The proteins were further divided into four subfamilies based on the phylogenetic relationship analysis. However, the low bootstrap values were displayed among C2H2-ZFPs in each subfamily (Fig. 1a), which we thought may due to the low sequence similarity of non-C2H2 domain sequences (Fig. S1). Our results showed the characteristics of *PoC2H2-ZFs*, including molecular weight, PI values, protein length, exon and intron number, and motif composition (Table S1, Fig. 1b and 1c), have a wide range of variations among proteins, suggesting the high diversity in structural and physicochemical properties maybe existed in *PoC2H2-ZFs*. These data suggesting that *PoC2H2-ZFs* may have distinct origins and showed diversity in function.

Conserved “QALGGH” sequences have been reported unique to the plant C2H2 domain (Takatsuji, 1999). In many plants, it was detected in most C2H2-ZFPs (Cao et al., 2016; Hu et al., 2019). In *P. ostreatus*, there was not found such conserved sequences in C2H2-ZFPs (Fig. 2a). The result of sequence alignment indicating the C2H2 domain in *P. ostreatus* can describe as C-X₍₂₋₄₎-CX₃FX₅LX₂H₍₃₋₅₎H, that F and L residues also showed the most conservative (Fig. 2a). Motif 1 encoding the characteristic motif of the C2H2 domain was detected distributed in all *PoC2H2-ZFPs* (Table S2, Fig. 1c). The conserved amino acid analysis of motif 1 indicating the signature sequences it encoded was corresponding to the result of sequence alignment (Fig. 2). These results suggesting the C-X₍₂₋₄₎-CX₃FX₅LX₂H₍₃₋₅₎H sequences were conserved in *PoC2H2-ZFPs*.

The *C2H2-ZFs* have been reported to participate in multiple growth and development processes in fungi. Investigate the expression profiles of *PoC2H2-ZFs* can help us understand the potential role of their involvement in growth and development in *P. ostreatus*. In *Verticillium dahlia*, the loss function of the C2H2 transcription factor VdMsn2 leads to a significant reduction in hyphal growth (Tian et al., 2017), indicating the impact of *C2H2-ZFPs* on hyphal

growth. In *P. ostreatus*, the *PeosPC15_2|1077016*, *PeosPC15_2|112393*, and *PeosPC15_2|1088285* were observed expression highly in mycelia (Fig. 3b), suggesting they may play an important role in mycelia growth. Previous studies have reported the *C2H2-ZFs* regulating the formation of primordia. Inactivation of *c2h2* in *S. commune* resulted in the aggregates formed, but couldn't further differentiate into primordia (Ohm et al., 2011). From our data, five genes (*PeosPC15_2|1079678*, *PeosPC15_2|1089905*, *PeosPC15_2|1111338*, *PeosPC15_2|1095114*, and *PeosPC15_2|1095325*) exhibited the increased expression from the mycelia to primordia (Fig. 3b), indicating they may be involved in the formation of primordia in *P. ostreatus*. Besides, *C2H2-ZFs* also have been reported involved in the development of the fruiting body. In *Aspergillus nidulans*, deletion of *nsdC*, a gene that encoded one C2H2 transcription factor, resulted in the loss of fruiting body formation (Kim et al., 2009). In our data, the expression of all *PoC2H2-ZFs* was increased from primordia to the young fruiting body (Fig. 3b), suggesting the *C2H2-ZFs* may play an important role in the development of the fruiting body in *P. ostreatus*. There are three genes (*PeosPC15_2|1088285*, *PeosPC15_2|1089905*, and *PeosPC15_2|1102653*) that showed the increased expression at the mature fruiting body (Fig. 3b), which implies that might be involved in the *P. ostreatus* ripening process. The *PsCZF1* gene encoding a C2H2-ZFs in *Phytophthora sojae* has been demonstrated involved in the production of oospores and swimming zoospores (Wang et al., 2009). Thus, the *PeosPC15_2|1088285*, *PeosPC15_2|1089905*, and *PeosPC15_2|1102653* seem to participate in the development of the spore (Fig. 3b).

In *Arabidopsis thaliana*, the ZINC FINGER PROTEIN 5 (*ZFP5*) was reported can mediate cytokinin and ethylene effects on the root hairs formation and growth (An et al., 2012). *ZFP6* has been identified as essential regulators of trichome initiation by integrating gibberellin and cytokinin (Zhou et al., 2013). In addition, *GhWIP2* encoded one C2H2-ZFP that mediating cell expansion during organ growth by modulating crosstalk between auxin, gibberellins, and abscisic acid in *Gerbera hybrida* (Ren et al., 2018). These results indicating *C2H2-ZFs* can integrate various hormones that regulating the multiple aspects of development processes. Auxin can be produced by *P. ostreatus* (Bose, Shah & Keharia., 2013), and auxin and cytokinin have been reported to affect mycelia growth by exogenous treatment (Ramachela & Sihlangu, 2016). In this study, members of *PoC2H2-ZFs* expression were showed a significant response to auxin and cytokinin in primordia (Fig. 4). Therefore, our data indicating that auxin and cytokinin may be involved in *PoC2H2-ZFs* function in growth and development processes.

Previous studies have revealed that *C2H2-ZFs* increased resistance to abiotic stress in plants. In *Arabidopsis*, root growth in transgenic plants with constitutive expression of *Zat10* showed more tolerance to heat stresses (Mittler et al., 2006). Overexpression of *ZAT18* in *Arabidopsis* increased the ability to tolerate drought in transgenic plants, while mutation of this gene resulted in decreased drought tolerance (Yin et al., 2017). In soybean, the expression of the *C2H2-ZF* gene *GmSCOF-1* was induced by low temperature, and the overexpression lines were showed increased cold tolerance that increases expression levels of cold-responsive genes (Kim et al., 2001). For *P. ostreatus* cultivation, bad environmental conditions always influence the growth and development processes. Like high temperature, always inhibit mycelial growth, disruption of the cell wall integrity and increased the risk of fungal contamination, reduce the yield of mushrooms (Qiu et al., 2018). From our data, members of *PoC2H2-ZFs* could be

induced by heat and cold stress (Fig. 5), indicating this important transcription factor may have a conserved function that responds to heat and cold in fungi. Notably, some genes like *PeosPC15_2|1089905* and *PeosPC15_2|1102653* were found induced by heat or cold stress (Fig. 5), suggesting these genes may play a variety of roles in the response to various stresses.

Conclusions

In this study, we identified 18 *C2H2-ZFs* in *P. ostreatus* genome. However, a wide range of variations was observed in their phylogenetic relationship, gene structure, motif composition, and so on. The different expression profiles of *PoC2H2-ZFs* suggest they play diverse roles in different tissue growth and development. In addition, hormones and abiotic stress induced expression suggested that *PoC2H2-ZFs* may involve multiple processes that hormones regulated as well as abiotic stress responses.

Figure 3

Expression analysis of *PoC2H2-ZFs* in different tissues.

(a) Mycelia (M), primordia (P), young fruiting body (Y F B), and mature fruiting body (M F B) were sampled to analyze the expression profiles of *PoC2H2-ZFs*. (b) The result of RT-qPCR was analyzed using the $2^{-\Delta CT}$ method and then transformed in log2 level to visualize in a heatmap.

a

b

Figure 4

Expression pattern of *PoC2H2-ZFs* under auxin and cytokinin treatment.

Twelve selected *PoC2H2-ZFs* were used to analyze their expression patterns at 1, 3 h after IAA and zeatin treatment, respectively. Primordia treatment with H₂O was analyzed as controls. The result was analyzed using the $2^{-\Delta\Delta CT}$ method. The data were compared using the student's t-test, and the asterisk indicates a significant difference at $P < 0.05$ (n = 3).

Figure 5

Expression pattern of *PoC2H2-ZFs* response to cold and heat stress.

The *PoC2H2-ZFs* were used to analyze their expression patterns at 1, 3 h after 4 °C and 38 °C treatment, respectively. Primordia cultured at room temperature (10-13 °C) were analyzed as controls. The result was analyzed using the $2^{-\Delta\Delta CT}$ method. The data were compared using the student's t-test, and the asterisk indicates a significant difference at $P < 0.05$ (n = 3).
