ABSTRACT

Background: Mungbean (*Vigna radiata* L. Wilczek) is one of the most important pulse crops, well-known for its protein-rich seeds. Growth and productivity are severely undermined by waterlogging.

Methods: In this study, we aim to evaluate how two promising phytohormones, namely cytokinin (CK) and gibberellic acid (GA₃), can improve waterlogging tolerance in mungbean by investigating key morphological, physiological, biochemical, and yield-related attributes.

Results: Our results showed that foliar application of CK and GA₃ under 5-day of waterlogged conditions improved mungbean growth and biomass, which was associated with increased levels of photosynthetic rate and pigments. Waterlogging-induced accumulation of reactive oxygen species and the consequently elevated levels of malondialdehyde were considerably reduced by CK and GA₃ treatments. Mungbean plants sprayed with either CK or GA₃ suffered less oxidative stress due to the enhancement of total phenolics and flavonoids levels. Improvement in the contents of proline and total soluble sugars indicated a better osmotic adjustment following CK and GA₃ treatments in waterlogged-exposed plants. Most fundamentally, CK or GA₃-sprayed waterlogged-stressed mungbean plants demonstrated better performance in the aforementioned parameters after the 15-day recovery period as compared to water-sprayed waterlogged-exposed plants. Our results also revealed that CK and GA₃ treatments increased yield-associated features in the waterlogged-stressed plant. Here, both phytohormones are efficient in improving mungbean resistance to waterlogging. However, CK was found to be more effective. Overall, our findings suggested that CK or GA₃ could be used for managing waterlogging-induced damage to mungbean and perhaps in other cash crops.

INTRODUCTION

Mungbean (*Vigna radiata* L. Wilczek) is considered a major source of pulse protein because of its high protein content in the seeds (20.97–31.32%) (USAID Agricultural Extension Support Activity, 2017; (Yi-Shen, Shuai & FitzGerald, 2018; Rahman et al., 2019). More fundamentally, the mungbean is gaining its popularity in the extensive rice-based cropping system, owing to its low fertilizer and pesticide requirements, which provides farmers with good economic benefits and nutritional security (DAE, 2018; Rahman et al., 2019; Hou et al., 2019; Bangladesh Water Development Board, 2020).

Waterlogging has become a major environmental problem in global agriculture (Kaur et al., 2020). Under waterlogged conditions, the mass of oxygen in the soil attenuates partially (hypoxic) or fully (anoxic) due to high microbial activity, and the resulting CO₂ accumulation in the root zone restricts root metabolism, aerobic respiration, ATP synthesis, and nutrient acquisition, resulting in a significant reduction in the growth, development, and biomass of roots and shoots (Najeeb et al., 2015; Gill et al., 2018; Dossa et al., 2019). Moreover, waterlogging impairs root permeability and causes root injury, leading to a decrement of hydraulic conductivity and consequent stomatal closure, resulting in a significant reduction in net photosynthetic and transpiration rates (Else et al., 2001; Anee et al., 2019). These also lead to the excess generation of reactive oxygen species (ROS) such as superoxide (O₂⁻), singlet oxygen (¹O₂), hydrogen peroxide (H₂O₂) and hydroxyl radical (*OH), which are harmful to biological macromolecules (Yeung et al., 2018; Zhou et al., 2020).

Plants can acclimatize to the adverse impact of waterlogging-mediated soil oxygen dearth through adapting various morphological, physiological, and biochemical mechanisms. The development of adventitious roots and faster stem elongation are some examples of morphological adaptations (Yamauchi et al., 2018), whereas reduced stomatal conductance and subsequent decrease in net photosynthetic rate are short-term physiological adaptations (Jacobsen et al., 2007; Bhusal et al., 2020). Additionally, to shield themselves from stress, waterlogged plants accumulate several osmoprotectants such as proline, soluble sugars, and sucrose (Tewari & Mishra, 2018). However, one of the most important adaptive mechanisms is a well-balanced antioxidant defense system that involves both enzymatic (e.g., superoxide dismutase, SOD; catalase, CAT; ascorbate peroxidase, APX; glutathione S-transferase, GST; glutathione peroxidase, GPX) and non-enzymatic (e.g., total phenolics, total flavonoids, carotenoids) antioxidants that scavenge overaccumulation of ROS (Garcia et al., 2020; Hasanuzzaman et al., 2020).

Since mungbean is a waterlogging sensitive crop, there must devise a strategy for effectively alleviating the destructive effect of waterlogging stress to improve mungbean production in flood-prone areas having intensive and erratic rains. In this context, the search for effective approaches propelled us to use phytohormones such as cytokinin (CK) and gibberellic acid (GA₃) for overcoming the problems associated with waterlogging.

Although there are several studies on the role of phytohormones on abiotic stress tolerance in crop plants, there are hardly any studies focusing on the coordinated actions of CK and GA₃ in modulating plant growth and physiology. In the present study, we examined whether CK and GA₃ protect mungbean from waterlogging damage. We also examined the regulatory roles of CK and GA₃ in improving waterlogging tolerance of mungbean by investigating the morpho-physiological and biochemical mechanisms through assessments of morpho-physiology, photosynthetic parameters, ROS metabolism, osmoregulation, and yield.

MATERIALS AND METHODS

Plant growth conditions

Mungbean genotype, VC6173-B, was used in the present study owing to their properties of short duration (80 days to maturity), greater grain weight (44 g/1,000 grain), and high yield potential (1.5 t ha⁻¹). Healthy seeds of VC6173-B were germinated following the procedures of [Rahman et al. \(2019\)](#). Afterward, six germinated seeds were sown in each plastic pot (height × diameter = 20 cm × 16 cm), having 8 kg of silt loam soil. The soil was fertilized as per the recommended dose ([Ahmmed et al., 2018](#)). Plants were kept free from pests and diseases. The average maximum and minimum temperature of the experimental area ranged from 32.6 to 22.8 °C, with 85.6% of relative humidity. The number of seedlings was thinned to two in each pot after the eighth day of germination and continues to grow in normal condition up to the imposition of treatments. The experiment was laid out in a completely randomized design (CRD) with four replications.

Imposition of waterlogging treatments

Before waterlogging exposure for the next 5 days, 15-day-old mungbean seedlings at the V₁ stage (when the first trifoliolate were fully developed) were grouped into four sets as (i) water-sprayed waterlogged-stress-free plants (Control), (ii) water-sprayed waterlogged-stressed plants (WL), (iii) cytokinin (CK), named kinetin-sprayed (50 mg L⁻¹) waterlogged-stressed plants (CK+WL) and (iv) gibberellic acid (GA₃)-sprayed (50 mg L⁻¹) waterlogged-stressed plants (GA₃+WL). It is worth noting that foliar spray with either CK or GA₃ or water (20 mL to each pot) was done two times daily (9.00 to 10.00 am, and 3.00 to 4.00 pm). Tween-20 surfactant (0.2%, v/v) was used to ensure maximum adherence of CK, GA₃, and water to the leaves. Notably, the level of water for creating waterlogging stress was maintained at 2.5 cm above the soil surface. Following the stress period, one set of seedlings (Set I) was immediately harvested, and another set (Set II) was harvested at 15-day after recovery to record the morpho-physiological and biochemical parameters. After stress exposure, one set of seedlings (Set III) was allowed to grow until harvest with optimum irrigation to determine yield-related attributes. Importantly, for determining various morphological, physiological, and biochemical parameters, the first trifoliolate leaves from the bottom of the plants were collected.

Determination of growth-related parameters

The growth performance of mungbean plants was assessed by measuring the shoot height, and dry weight (DW) of both shoots and roots. Additionally, the stem girth of the mungbean plants was determined using a slide caliper.

Measurement of photosynthetic parameters

Gas exchange features, including photosynthesis rate (P_n), stomatal conductance to water (H_2O) (g_s), and transpiration rate (E) of mungbean plants were measured using the LI-6400XT portable photosynthesis system (LI-COR Biosciences, Lincoln, NE, USA) from 11.00 AM to 2.00 PM under full sun-light conditions. The parameters P_n , g_s , and E were used for assessing the instantaneous water-use efficiency (WUE_{ins}; ratio P_n/E) and intrinsic water-use efficiency (WUE_{int}; ratio P_n/g_s). The freshly harvested mungbean leaves were used to determine the contents of chlorophylls (Chls) [Chl *a*, Chl *b* and Chl (*a+b*)] by using the visible spectrophotometer (Model: T60 UV, PG Instruments Limited, Leicestershire, UK) according to the protocols described by [Lichtenthaler & Wellburn \(1983\)](#). The contents of total phenolic and total flavonoid were quantified following the methods of [Ainsworth & Gillespie \(2007\)](#), and [Zhishen, Mengcheng & Jianming \(1999\)](#), respectively.

Measurement of oxidative stress indicators

Fresh leaf tissues (0.5 g) were homogenized in 3 mL of 5% (w/v) trichloroacetic acid (TCA). After centrifugation at 11,500× *g* for 10 min, the supernatant was used to determine H_2O_2 and malondialdehyde (MDA). The H_2O_2 content was determined spectrophotometrically according to the procedure of [Yu, Murphy & Lin \(2003\)](#) with some modifications. Briefly, 400 μ L supernatant was added to 400 μ L of 10 mM potassium phosphate buffer (pH 7.0) and 800 μ L of 1 M potassium iodide (KI). The reaction was allowed to proceed in the dark for 1 h before measuring the absorbance at 390 nm. The H_2O_2 concentration was calculated using the extinction coefficient of 0.28 μ M⁻¹ cm⁻¹. The methods of [Heath & Packer \(1968\)](#) were followed for MDA determination. The MDA content was calculated using an extinction coefficient of 155 mM⁻¹ cm⁻¹ and represented as nmol g⁻¹ fresh weight (FW).

Quantification of proline and soluble sugar content

Leaf proline content was measured spectrophotometrically by an acid-ninhydrin method using the procedure outlined by [Bates, Waldren & Teare \(1973\)](#). The proline content was calculated using a standard curve and reported as μ mol g⁻¹ FW. Freshly harvested leaf tissues were used for the quantification of total soluble sugar levels following the comprehensive protocols described by [Somogyi \(1952\)](#).

Statistical analysis

The obtained data were subjected to a one-way analysis of variance (ANOVA) using Statistix software (version 10). Different alphabetical letters were used to denote the significant variations among different treatments at the $P < 0.05$ level following a least

RESULTS

CK and GA₃ supplementation improved growth parameters of mungbean plants during waterlogging stress and recovery period

In comparison with control plants, WL plants displayed a significant decrease in shoot height, shoot DW, root DW, and stem girth by 34%, 37%, 42%, and 37%, respectively; however, following 15-day of recovery, these parameters were reduced by 35%, 44%, 36% and 32%, respectively (Table 1). On the other hand, CK+WL and GA₃+WL plants showed noteworthy improvement in shoot height by 36% and 26%, shoot DW by 38% and 27%, root DW by 36% and 26%, and stem girth by 36% and 31%, respectively, when compared with WL plants (Table 1). Following the recovery period, a substantial enhancement in shoot height (35% and 24%), shoot DW (38% and 27%), root DW (36% and 26%), and stem girth (36% and 31%) was observed in the CK+WL and GA₃+WL plants, respectively, in comparison with WL plants (Table 1).

Exogenous CK and GA₃ enhanced gas exchange features of mungbean plants during waterlogging stress and recovery period

Plants subjected to waterlogging stress and subsequent recovery period showed a decrease in P_n (by 44% and 42%), g_s (90% and 53%) and E (74% and 36%, respectively) when compared with control plants (Figs. 1A–1C). Nonetheless, the levels of WUE_{int} and WUE_{ins} in WL plants increased by 515% and 118%, respectively relative to control plants, whereas the level of WUE_{int} and WUE_{ins} in control and WL plants was comparable after the recovery period (Figs. 1D, 1E). On the other hand, CK+WL and GA₃+WL plants exhibited decreased levels of g_s (by 40% and 27%) and E (33% and 23%), and increased levels of P_n (by 37% and 27%), WUE_{int} (119% and 64%) and WUE_{ins} (100% and 61%, respectively) when compared with that of WL plants (Figs. 1A–1E). Similarly, following the recovery period, decreased levels of g_s (by 36% and 28%) and E (34% and 21%), and increased levels of P_n (37% and 27%), WUE_{int} (115% and 73%), and WUE_{ins} (107% and

59%) were recorded in CK+WL and GA₃+WL plants, respectively, as compared with that of WL plants (Figs. 1A–1E).

CK and GA₃ prevented damage to photosynthetic pigments during waterlogging stress and recovery period

Compared to control plants, a sharp decline in the contents of Chl *a* (by 50.10% and 43%), Chl *b* (65.44% and 63%), and Chl (*a*+*b*) (54% and 49%) were observed in the leaves of WL plants following stress and recovery periods, respectively (Figs. 2A–2C). In contrast, CK and GA₃ supplementation protected the photosynthetic pigments from waterlogged-induced deleterious effects by enhancing the contents of Chl *a* (by 74% and 61%), Chl *b* (142% and 124%), and Chl (*a*+*b*) (88% and 74%) in the leaves of CK+WL and GA₃+WL plants, respectively (Figs. 2A–2C). Furthermore, following the recovery period,

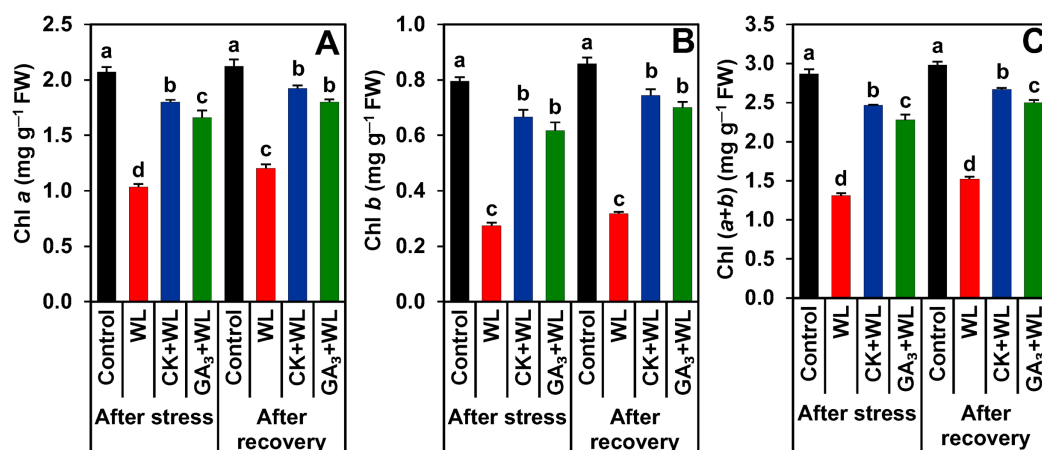

Figure 2 Effects of exogenous cytokinin and gibberellic acid on (A) Chlorophyll (Chl) *a*, (B) Chl *b* and (C) Chl (*a* + *b*) in the leaves of mungbean plants after 5-day of stress and 15-day of recovery period. Data represent means of four independent replicates ($n = 4$). Vertical bars indicate standard errors. Different letters represent significant differences at $P < 0.05$ (least significant difference test). WL, water-sprayed waterlogged-stressed plants; CK+WL, cytokinin (CK)-sprayed (50 mg L^{-1}) waterlogged-stressed plants; GA₃+WL, gibberellic acid (GA)-sprayed (50 mg L^{-1}) waterlogged-stressed plants; FW, fresh weight. Full-size [DOI: 10.7717/peerj.12862/fig-2](https://doi.org/10.7717/peerj.12862/fig-2)

the leaves of CK+WL and GA₃+WL plants also displayed a significant rise in the content of Chl *a* (by 60% and 50%), Chl *b* (134% and 120%), and Chl (*a*+*b*) (75% and 64%, respectively) in comparison with WL plants (Figs. 2A–2C).

Exogenous CK and GA₃ suppressed oxidative stress markers in mungbean plants during waterlogging stress and recovery period

Imposition of waterlogging stress and following recovery period substantially increased the contents of H₂O₂ (by 113% and 62%) and MDA (179% and 100%, respectively) in the leaves of WL plants, relative to that of control plants (Figs. 3A, 3B). CK and GA₃ treatment resulted in reductions of H₂O₂ (by 57% and 45%) and MDA (29% and 19%) contents in the leaves of CK+WL and GA₃+WL plants, respectively, in comparison with WL plants (Figs. 3A, 3B). Similarly, compared with the WL plants, substantial decreases in the contents of H₂O₂ (by 37% and 26%) and MDA (34% and 21%) were noticed in the leaves of CK+WL and GA₃+WL plants, respectively, in the recovery period (Figs. 3A, 3B).

CK and GA₃ enhanced the synthesis of osmolytes and non-enzymatic antioxidants in mungbean plants during waterlogging stress and recovery period

Exposure of mungbean plants to waterlogging stress and followed by a recovery period exhibited a rise in the contents of proline (63% and 42%), total soluble sugars (33% and 20%), total phenolics (58% and 23%), and total flavonoids (31% and 16%, respectively) in the leaves of WL plants when compared with that of control plants (Figs. 3C–3F). In comparison with WL plants, CK+WL and GA₃+WL plants displayed enhanced levels of proline (by 34% and 21%), total soluble sugars (32% and 22%), total phenolics

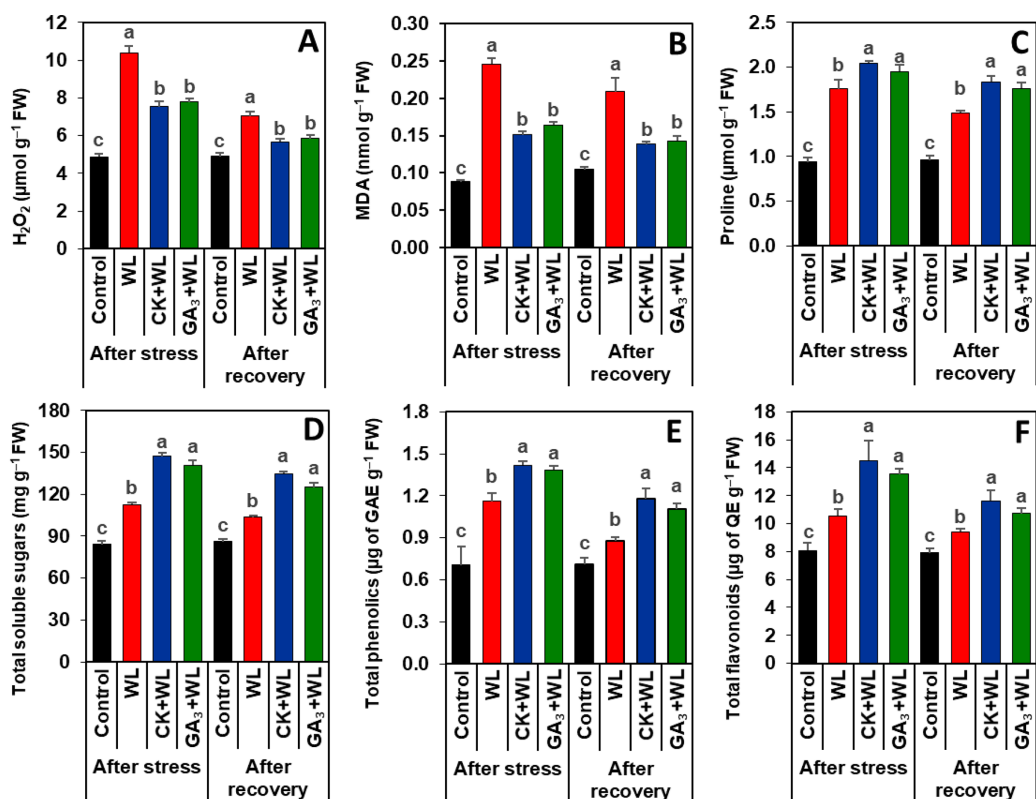

Figure 3 Effects of exogenous cytokinin and gibberellic acid on the contents of (A) H_2O_2 , (B) MDA, (C) proline, (D) total soluble sugars, (E) total phenolics and (F) total flavonoids in the leaves of mungbean plants after 5-day of stress and 15-day of recovery period. (36% and 24%), and total flavonoids (37% and 28%, respectively) (Figs. 3C–3F). Similarly, in the WL plants, the levels of proline, total soluble sugars, total phenolics, and flavonoids were noticeably enhanced in CK+WL leaves by 34%, 35%, 34%, and 35%, respectively, and in GA_3 +WL leaves by 23%, 27%, 23% and 25%, respectively, followed by a recovery period (Figs. 3C–3F).

CK and GA_3 supplementation increased seed yield of mungbean plants

Compared to the control, WL plants displayed notable decrements in pod length (by 13%), the total number of pods per plant (36%), thousand seed weight (13%) and seed yield per plant (42%) (Table 2). Significant improvement in pod length (by 8% and 7%), the total number of pods per plant (19% and 16%), and seed yield per plant (20% and 17%) were observed in CK+WL and GA_3 +WL plants, respectively, when compared with that of WL plants (Table 2).

DISCUSSION

Waterlogging leads to detrimental consequences on a number of crop plants, including mungbean (Amin *et al.*, 2015; Donat *et al.*, 2016). The current study investigated the effective mitigation of waterlogged-induced damage to mungbean plants by exploring the potential role of CK and GA₃.

In the present study, waterlogging-induced deleterious effects were evident as a reduction of shoot height, shoot and root DW, and stem girth; however, the foliar application of CK and GA₃ partially alleviated those waterlogged-mediated detrimental effects. It is well reported that both CK and GA₃ played a pivotal role in cell elongation and other growth and development processes (Ahanger *et al.*, 2018; Wang *et al.*, 2019; Rady *et al.*, 2021), which resulted in enhanced growth and biomass of mungbean under waterlogging in the present study.

The waterlogged-induced growth inhibition and biomass reduction in mungbean plants might be a consequence of impeded photosynthesis. It is envisaged that at the beginning of waterlogging stress, plant roots rapidly transmit a xylem-borne signal to the leaves in the form of hormones, most notably abscisic acid (ABA) to slow down the process of transpiration through stomatal closure, and thus attenuate carbon dioxide availability in leaves (Jackson *et al.*, 2003; Najeeb *et al.*, 2015). This was due to the decline in root hydraulic conductivity and inadequate ATP production during waterlogging as reported by other researchers (Steffens *et al.*, 2005; Kaur *et al.*, 2019). Henceforth, the supply of photoassimilates from leaves to different plant parts is also reduced, which ultimately leads to poor plant growth and biomass production (Kogawara *et al.*, 2006). Apart from these, waterlogged-induced reduction of photosynthetic pigments, including Chl *a* and *b*, is also responsible for reduced net photosynthetic rate (Ren *et al.*, 2016; Zhang *et al.*, 2020), as also observed in the present study (Figs. 1A and 2A–2C). On the other hand, mungbean plants treated with CK and GA₃ significantly improved the net photosynthetic, as well as the contents of Chl *a* and Chl *b* under waterlogged conditions, implying that CK and GA₃ played a pivotal role in improving the photosynthetic process during waterlogging stress. Improvements in photosynthesis, as well as photosynthetic pigments, were also observed after the recovery period in response to CK and GA₃ supplementation. This was due to the fact that phytohormones could regulate

photoprotection of the photosynthetic apparatus under stress conditions and they controlled the production and scavenging of photosynthesis-derived ROS, the duration and extent of photo-oxidative stress, and redox signaling (Müller & Munné-Bosch, 2021).

We also observed that in comparison with WL plants, CK or GA₃-treated plants demonstrated remarkably improved WUE, indicating that CK and GA₃ might enable mungbean plants to produce more biomass under the conditions of limited water uptake. Surprisingly, after the recovery period, we have seen similar positive effects of CK and GA₃ in boosting WUE. It is well-known that improving WUE in abiotic-stressed plants without deteriorating growth and yield is scrutinized as a paramount goal of current plant breeding programs (Yang et al., 2016). The increase in WUE was mainly due to the enhancement of photosynthetic parameters. Our findings support this phenomenon and corroborate with the previous findings where the external application of CK to cold-stressed coffee (*Coffea arabica*) and GA₃ to drought-stressed *Vicia faba* seedlings improved WUE (Acidri et al., 2020; Rady et al., 2021).

Water stagnation because of waterlogging conditions causes poor gas exchange between soils and plant roots, resulting in hypoxia or anoxia in plant tissues (Matin & Jalali, 2017). The scarcity of oxygen induces leakage of electrons from mitochondria, which together with impaired photosynthesis, triggers a burst of excessive ROS production, causing oxidative damage to waterlogged-stressed seedlings (Xu et al., 2013), and was manifested in our study with increasing H₂O₂ and MDA in WL plants (Figs. 3A, 3B). External application of either CK or GA₃ to waterlogged-stressed mungbean plants resulted in a dramatic reduction in ROS accumulation, implying that CK and GA₃ play an important role in reducing oxidative burden induced by ROS and providing protection to plasma membrane integrity. It is well established that phytohormones controlled the production and scavenging of photosynthesis-derived ROS and also enhanced antioxidant defense (Müller & Munné-Bosch, 2021). In line with our study, previous reports also demonstrated that the contents of H₂O₂ and MDA were noticeably diminished in salt-stressed tomato (*Solanum lycopersicum*) and okra (*Abelmoschus esculentus*) by CK application, and drought-stressed wheat (*Triticum aestivum*) and boron-stressed tomato by GA₃ application (Ahanger et al., 2018; Wang et al., 2019; Moumita et al., 2019; Javed et al., 2021).

Our results also demonstrated that, compared with WL, the leaves of CK+WL and GA₃+WL plants accumulated higher levels of non-enzymatic antioxidants, namely total phenolics and total flavonoids (Figs. 3E, 3F). More fundamentally, following the recovery period, there was a similar pattern of improvement in total phenolics and total flavonoids levels in response to CK or GA₃ application. Phenolics and flavonoids are two well-known secondary metabolites that play a pivotal role in scavenging free radicals and preventing lipid peroxidation, thus maintaining membrane fluidity and shielding cell membrane damage from oxidative damage under different abiotic stresses, including waterlogging (Ahmad et al., 2010; Patel et al., 2020; Elkesh et al., 2020). These results implied that either CK or GA₃-induced alleviation of ROS burden was most likely due to the heightened level of non-enzymatic antioxidants. It is worth noting that the application of CK to mungbean plants displayed a greater role in alleviating the contents of H₂O₂

and MDA by enhancing the levels of total phenolics and flavonoids when compared with the plants treated with GA₃. *Ahanger et al. (2018)* reported that CK application to salt-stressed tomato plants increased the level of total phenolics and flavonoids, while *Rady et al. (2021)* revealed that GA₃ supplementation to drought-stressed faba bean plants increased phenolics accumulation.

To overcome waterlogged-induced osmotic stress, plants also accumulate several compatible solutes, including proline and total soluble sugars, which play vital roles in maintaining water balance, retrieving photosynthetic functions, stabilizing cellular components, ROS scavenging, improving cellular signaling, and secondary metabolite biosynthesis (*Barickman, Simpson & Sams, 2019; Chávez-Arias, Gómez-Caro & Restrepo-Díaz, 2019; Xiao et al., 2020*). Our data on compatible solutes revealed that the levels of proline and total soluble sugar were dramatically enhanced in WL plants (Figs. 3C, 3D). Importantly, exogenous application of CK and GA₃ further enhanced the contents of proline and total soluble sugars in the leaves of CK+WL and GA₃+WL plants, and this trend was similar following the recovery period (Figs. 3C, 3D). Our findings coincided with the results of *Sarafraz-Ardakani et al. (2014)*, who also observed that CK supplementation increased the amount of proline and soluble sugars in drought-stressed wheat plants.

Waterlogged-stressed mungbean plants showed a decrease in yield-associated features such as pod length, the total number of pods per plant, thousand seed weight, and seed yield per plant, which might be correlated with poor plant growth because of impaired photosynthesis and enhanced accumulation of ROS (*Kumar et al., 2013*). In contrast, foliar application of either CK or GA₃ to waterlogged-exposed mungbean plants resulted in a dramatic increase in pod length, the total number of pods per plant, thousand seed weight, and seed yield per plant. These results suggested that CK or GA₃ supplementation improved photosynthetic efficiency of mungbean to sustain higher levels of total soluble sugars, as well as heightened levels of proline and non-enzymatic antioxidants to resist the phytotoxic effects of waterlogging through the reductions of ROS-mediated oxidative stress, resulting in improvement of yield performance. Yield improvement in wheat plants under heat and drought stress was also reported upon supplementation of CK and GA₃, respectively (*Gupta, Agarwal & Gupta, 2012; Yang et al., 2016*).

CONCLUSIONS

Our work revealed that treating plants with either CK or GA₃ positively regulates defense responses in waterlogged-stressed mungbean plants through regulating several physiological and biochemical mechanisms. The CK and GA₃-sprayed plants demonstrated improvement in plant height, stem girth, and plant biomass and a decreased level of ROS accumulation and consequent MDA level, implying that CK and GA₃ played a decisive role in controlling ROS-induced cellular damage. These observations were closely interlinked to heightened levels of non-enzymatic antioxidants, including total phenolics and total flavonoids. Elevated levels of proline and total soluble sugars in CK and GA₃-sprayed plants also contributed to the maintenance of better water status and osmotic adjustment under waterlogging. Such positive regulatory roles of CK and GA₃ also persisted after the 15-day recovery period. All the studied physiological and biochemical

mechanisms in CK and GA₃-sprayed plants contribute to improving the yield-associated features of mungbean plants.

These findings imply that CK and GA₃ could be used as a potential chemicals for reducing the negative impacts of waterlogging on crops and on agricultural production to ensuring the sustainability of agriculture in flood-prone areas.

ACKNOWLEDGEMENTS

The support from the Analytics Lab of the Department of Crop Botany, Bangabandhu Sheikh Mujibur Rahman Agricultural University is gratefully acknowledged.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

The work was supported by a grant from the Bangladesh Bureau of Educational Information and Statistics (BANBEIS), Ministry of Education, Government of the People's Republic of Bangladesh under the Higher Educational Research Program. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
Bangladesh Bureau of Educational Information and Statistics.
Ministry of Education.
Government of the People's Republic of Bangladesh under the Higher Educational Research Program.

Competing Interests

Mirza Hasanuzzaman is an Academic Editor for PeerJ.

Author Contributions

- Md. Rafiqul Islam conceived and designed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Md. Mezanur Rahman performed the experiments, analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Mohammed Mohi-Ud-Din analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Munny Akter performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Erin Zaman performed the experiments, authored or reviewed drafts of the paper, and approved the final draft.
- Sanjida Sultana Keya performed the experiments, authored or reviewed drafts of the paper, and approved the final draft.
- Mehfuz Hasan performed the experiments, authored or reviewed drafts of the paper, and approved the final draft.

- Mirza Hasanuzzaman analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.

Data Availability

The following information was supplied regarding data availability:

The raw data are available in the [Supplemental File](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.12862#supplemental-information>.
