**Background**: Full vaccination refers to the administration of vaccines/antigens recommended for children in the first year of life. However, little is known about full vaccination in remote, rural Ethiopia. This study aimed to measure full vaccination coverage among children aged 12 to 23 months and associated factors in Demba Gofa District, Southern Ethiopia. **Methods**: A cross-sectional community-based study was conducted in April and May 2019 using a multistage sampling technique to select 677 mothers with children 12-23 months of age. Data was collected using a pre-tested structured questionnaire, and data were edited, coded, entered, and cleaned using Epi Info v3.1 and analyzed using SPSS v20. Bivariate and multivariable logistic regression was used to understand associations between dependent and independent variables. **Results:** Three-hundred and nine children (47.0%) were fully vaccinated, 274 (41.7%) were partially vaccinated, and 74 (11.3%) were not vaccinated at all. Children were more likely to be vaccinated if decisions were made jointly with husbands (AOR=1.88, 95% CI: 1.06, 3.34), were made by mothers (AOR=4.03, 95% CI: 1.66, 9.78), followed postnatal care (AOR=5.02, 95% CI: 2.28, 11.05), if the child's age for completing vaccination was known (AOR=2.54, 95% CI: 1.04, 6.23), and if vaccinations did not make the child sick (AOR=0.32, 95% CI: 0.16, 0.64). **Conclusion:** Full vaccination coverage was less than average in the study district and far below the governmental target (90%) necessary for sustained control of vaccine-preventable diseases. Interventions targeted towards maternal healthcare decision-making, postnatal care, knowledge on vaccination timing, and importance should be prioritized to improve full vaccination coverage.

## Abstract

19  **Background**: Full vaccination refers to the administration of vaccines/antigens recommended

20  for children in the first year of life. However, little is known about full vaccination in remote,

21  rural Ethiopia. This study aimed to measure full vaccination coverage among children aged 12 to

22  23 months and associated factors in Demba Gofa District, Southern Ethiopia.

23  **Methods**: A cross-sectional community-based study was conducted in April and May 2019 using

24  a multistage sampling technique to select 677 mothers with children 12-23 months of age. Data

25  was collected using a pre-tested structured questionnaire, and data were edited, coded, entered,

26  and cleaned using Epi Info v3.1 and analyzed using SPSS v20. Bivariate and multivariable

27  logistic regression was used to understand associations between dependent and independent

28  variables.

29  **Results:** Three-hundred and nine children (47.0%) were fully vaccinated, 274 (41.7%) were

30  partially vaccinated, and 74 (11.3%) were not vaccinated at all. Children were more likely to be

31  vaccinated if decisions were made jointly with husbands (AOR=1.88, 95% CI: 1.06, 3.34), were

32  made by mothers (AOR=4.03, 95% CI: 1.66, 9.78), followed postnatal care (AOR=5.02, 95%

33  CI: 2.28, 11.05), if the child's age for completing vaccination was known (AOR=2.54, 95% CI:

34  1.04, 6.23), and if vaccinations did not make the child sick (AOR=0.32, 95% CI: 0.16, 0.64).

35  **Conclusion:** Full vaccination coverage was less than average in the study district and far below

36  the governmental target (90%) necessary for sustained control of vaccine-preventable diseases.

37  Interventions targeted towards maternal healthcare decision-making, postnatal care, knowledge

38  on vaccination timing, and importance should be prioritized to improve full vaccination

39  coverage.

41

## Introduction

42
43 vaccination is the efficient way to protect people from infectious diseases by stimulating the host

44 immune system to produce antibodies or other specific immune defenses.  (1, 2). Vaccination has

45 reduced and eliminated various childhood diseases globally, including diphtheria, tetanus,

46 pertussis, polio, measles, and tuberculosis. Several new vaccines have now been added to public

47 health programs (hepatitis B, *Haemophilus influenzae* B (HiB), pneumococcus, and rotavirus) (3-

48 10). Global vaccination coverage has increased, contributing to decreases in child mortality from

49 9.6 million in 2000 to 5.9 million in 2015, especially low and middle-income countries (LMICs)

50   _ _  (3,11-18).

51 The World Health Organization (WHO) recommends, which is also strictly endorsed by

52 Ethiopia, states that a child is fully vaccinated if he/she has the BCG (tuberculosis) vaccine at

53 birth; oral polio vaccine (OPV) at birth, 6, 10, and 14 weeks; pentavalent vaccine for diphtheria,

54 tetanus, pertussis (whooping cough), hepatitis B, and HiB at 6, 10, and 14 weeks; pneumococcal

55 conjugate vaccine (PCV) at 6, 10, and 14 weeks; rotavirus at 6 and 10 weeks; inactivated polio

56 vaccine (IPV) at 14 weeks; and measles at 9 months (4-6). The Expanded Program on

57 Immunization (EPI) agenda plans by applying WHO standards to give the primary vaccination

58 series to at least 90% of children. Despite these efforts, the target has still to be attained in many

59 LMICs (5,19-25). For instance, each day over 20,000 children die from preventable infectious

60 diseases, and a larger part of these deaths occur in sub-Saharan Africa (SSA) and South East

61 Asia (SEA) compared to the rest of the world (7,9,26-29).

62 Globally, 22.6 million infant children are partially protected through vaccination and over 25%

63 of these are reported to be in LMICs (14-16). An estimated 2.5 million children aged less than

64 five years die annually due to diseases that can be prevented by vaccination (11, 15,30). About

65 14.8 million children who are not vaccinated with pentavalent 3 before celebrating their first year

66 are found only in ten countries, including Ethiopia (14,15,29,30). In spite of the fact that most

67 under-five deaths can be easily tackled by vaccination, about half occur in SSA (4,6,31-38). The

68 most common vaccine preventable diseases  that result in morbidity and mortality under-five

69 children are pneumonia, diarrheal diseases and measles. More than three million cases of

70 pneumonia is reported eah year claiming the lives of  about 20% of an estimated 40,000 annual

71 underfie death. Diarrehal diseases follows accounting 1.7 million cases per year and measles

72  being the third with the 50 per one million population per year with the case fatality rate of 3-
73  6%(39,40). Ethiopia aimed to target at least 90% of the population with all vaccines by 2020.
74  However, studies conducted in Ethiopia in children aged 12-23 months have reported
75  vaccination rates from 39% to 43%. Full vaccination  coverage highly discripant at the regional
76  level lowest   in Afar with 15%highest Addis Ababa 89%,  , with different factors including
77  sociodemographic and economic factors, maternal healthcare service utilization, knowledge and
78  attitudes of mothers/caregivers towards vaccination, accessibility, and perceived availability
79  identified to affect full vaccination coverage (21,22,38,39).
80  However, there is still a lack of information on the prevalence and associated factors of full
81  vaccination coverage across different regions of Ethiopia and areas of the country where
82  epidemics intermittently occur. This study therefore aimed to measure the coverage of full
83  vaccination and associated factors among children aged 12 to 23 months in Demba Gofa District,
84  Southern Ethiopia to assist program implementers and frontline health workers understand the
85  factors influencing full vaccination coverage and to plan for default tracing mechanisms.
86

## 87  Materials & Methods

88  Study setting and design

89  A community-based cross-sectional study was conducted in April and May 2019 in the Demba
90  Gofa District, Ethiopia, which is located in Southern Ethiopia 514 km from Addis Ababa. The
91  district contains 34 kebeles, all rural, with a total population of 96,427; 1,659 (1.72%) were
92  children aged 12-23 months. Demba Gofa District has four governmental health centers, 34
93  health posts, and 15 private primary clinics. The EPI service was provided only by governmental
94  health facilities (45).

95  Patient and public involvement
96  Not applicable for this study.

97  Source population
98  The source population was all children aged 12-23 months paired with their mothers/caregivers.

99    Inclusion/exclusion criteria

100    The inclusion criteria were all mothers/caregivers with children aged 12-23 months who were

101    residents of selected kebeles (for at least six months) in the district, while exclusion criteria were

102    mentally disabled/critically ill mothers/caretakers.

103    **Sample size determination**

104    The sample size was determined using the single population proportion formula and P=27.7% as

105    the prevalence of full immunization coverage among children aged 12-23 months in Ambo

106    district, Central Ethiopia (41). By using a 95% level of significance, a margin of error of 5%, a

107    design effect of 2, and a non-response rate of 10%, the final sample size was 677:

108    $$n = \frac{(Z\alpha/2)^2 p(1-P)}{d^2}$$

110    Sampling procedure

111    Multi-stage sampling was used to select the study population at the community level. In the first

112    stage, ten kebeles were selected using a simple random sampling method from a total of 34

113    kebeles in the district. The total sample size was divided by the size of all households that had

114    children aged 12-23 months in each selected kebele. Then, the total sample size was

115    proportionally allocated according to the number of children in each kebele. Finally, a simple

116    random sampling method was employed to select children using the lottery method from each

117    kebele. When there were two or more children in the same household, the lottery method was

118    used to select only one. During absence of eligible child in the household, the next one was

119    included. If eligible participants absent during data collection, households are revisited twice by

120    the interviewers.

121    Data collection and quality control

122    Data were collected using a pre-tested and structured questionnaire developed from the related

123    literature used to conduct similar study in elsewhere(8-11). The questionnaire was initially

124    prepared in English and then translated to Gofatho (local Gofa language) and then translated

125    back into English by the qualified translators to check for consistency. Data were collected

126    through face-to-face interviews from mothers/caregivers. Training was given for two days before

127    data collection by the principal investigator to the data collectors and supervisors on the purpose of

128    the study, data collection tools, and on minimizing the recall bias. Mothers/caregivers were asked to

129    show vaccination cards (if available, the interviewer copied the vaccination dates), and for those

130    who had no or lost vaccination cards, mothers/caregivers were asked about the vaccination status

131    of their children using different recall mechanisms such as asking the route of administration,

132    injection sites, examining the BCG scar, etc. Pretesting was performed in 5% (8,23)of the sample

133    size in kebeles outside of the study area after which necessary modifications were undertaken.

134    Daily check-ups were performed for data completeness, accuracy, and consistency.

135    Operational definitions

136    **Fully vaccinated:** A child aged 12-23 months who received one dose of BCG, at least three

137    doses of OPV, three doses of pentavalent, three doses of PCV, two doses of Rota, and one dose

138    of measles vaccines before celebrating the first birth year(10).

139    **Partially vaccinated:** If a child missed at least one dose of the ten vaccines mentioned

140    above(10).

141    **Unvaccinated:** A child who had not received any of the ten vaccines(10).

142    **Knowledge of vaccination:** A mother/caregiver answering a mean or above of knowledge

143    questions was considered to have good knowledge, while a mother/caregiver answering below a

144    mean of knowledge questions was considered to have poor knowledge(8,14).

145    **Attitude towards vaccination:** When the respondent answered the mean and above of the ten

146    attitude questions were deemed to have a positive attitude and those answering below the mean

147    were deemed to have a negative attitude(8,14).

148    Data management and analysis

149    After data collection, data were edited and coded for completeness and consistency and then

150    entered into Epi Data v3.1 and exported to SPSS v20 for analysis. After cleaning data for

151    inconsistencies, errors, and missing values, descriptive statistics (mean, median, SD, percent,

152    frequency) were calculated to visualize the overall distribution of the study subjects for the

153    variables under study. Bivariate analysis was performed to determine associations between

154    independent and full vaccination status. Multicollinearity was checked using a cutoff <10 based

155    on the variance inflation factor (VIF) or tolerance test >0.1. The necessary assumptions of

156    logistic regression were checked using Hosmer and Lemeshow tests to assess the fitness of the

157  model at a P-value < 0.05. All explanatory variables associated with the full vaccination status at

158  p-value ≤0.25 were selected for multivariable analysis. Finally, multivariate analysis was used to

159  measure the degree of association between independent and outcome variable. Adjusted odds

160  ratio(AOR) with 95% CI was used to determine statistically significant.

161  Ethical considerations

162  Ethical approval was obtained from the Research Ethical Review Committee of the College of

163  Health Sciences and Medicine of Wolaita Sodo University under the number CHSM/ERC/42.

164  An official letter of cooperation was taken to the Gofa Zone Health Department and Demba Gofa

165  District Health Office and a permission letter was then received from each. Official letters also

166  were written to the kebele administration and health posts. Informed written consent was

167  obtained from particpants after explaining the aims of the study, and the confidentiality and

168  anonymity of information was preserved.

169

170  **Results**

171  **Socio-demographic and economic characteristics of study participants**

172  From a total of 677 mothers with children aged 12-23 months old, 657 were interviewed, a

173  response rate of 97%. Most respondents (632, 96.2%) were mothers of the children, 77.8% were

174  Protestant, 634 (96.5%) were married, and all were of Gofa ethnicity. The majority of

175  mothers/caregivers (260, 39.6%) were illiterate, and most husbands (497, 75.6%) were farmers.

176  131 (19.9%) families were grouped into the richest wealth quantile. The average family size was

177  5.79 with a range from 2 to 12. Over half (376, 57.2%) of the children were male, and most

178  belonged to families with multiple children (**Table 1**).

179  **Maternal healthcare service utilization**

180  Four hundred and sixty-eight (72.0%) mothers sought healthcare services through joint decisions

181  with their husbands. Most respondents (545, 83.8%) had received antenatal care (ANC) during

182  their last pregnancy, most (517, 79.5%) had attended ANC at least two or more times, and 485

183  (74.6%) had taken tetanus injections. Four hundred and twenty-five (65.4%) mothers gave birth

184  to their last baby in healthcare institutions, but only 62 (9.5%) mothers attended postnatal care at

185  least once (**Table 2**).

**Knowledge and attitudes of mothers/caregivers towards vaccination and vaccine-preventable disease**

Of 657 total respondents, 603 (92.8%) had ever heard about vaccination and vaccine-preventable diseases. The majority of respondents (549, 91.0%) heard about vaccination and vaccine-preventable diseases from health care workers. Nearly half of the respondents (308, 47.4%) mentioned measles as a specific vaccine-preventable disease, and 210 (32.3%) mentioned tetanus. Respondents were also asked the objective of vaccinating children, the age at which a child should begin vaccination, the sessions needed to complete vaccination, and the correct age at which a child completes its vaccination program. Regarding knowledge, almost three-quarters (487, 74.0%) of study participants have a good knowledge, whereas 469 (71.4%) of study subjects have a positive attitude towards vaccination.

**Accessibility and vaccination coverage**

All respondents reported that they had access to a health facility that provided vaccination services near them. Over 90% of health facilities that provided vaccination services in the Demba Gofa District were reported to be health posts. With respect to vaccination delivery strategy, 351 (53.4%) were static, 158 (24.0%) were outreach, and 148 (22.5%) were home to home.

From a total of 657 children aged 12-23 months old, under half (309, 47.0%) were fully vaccinated or completed all the recommended vaccines before celebrating their first birthday. No child had a vaccination card, and all data were collected by recall alone. The reasons mentioned for partial and unvaccinated children were absenteeism of vaccinators, time inconvenience, not knowing the exact vaccination date, beliefs that vaccination has no use, fear of side effects, and religious and cultural issues.

**Factors associated with full vaccination coverage**

In bivariate analysis, there were significant associations between full vaccination status and the type of respondent, level of education of mother/caregiver, maternal healthcare decision-making, number of ANC attendances, number of tetanus vaccinations, post-natal care attendance, having information on vaccination and vaccine-preventable diseases, aim for vaccination, number of vaccine-preventable diseases known by the respondent, age at which a child began vaccination, sessions needed to complete vaccination, age at which a child completed vaccination, and whether a vaccination made a child sick or not.

217   In multivariable analysis, maternal healthcare decisions made jointly with husbands [AOR =
218   1.88, 95% CI (1.06, 3.34)], maternal healthcare decision made by mothers [AOR = 4.03, 95% CI
219   (1.66, 9.78)], number of post-natal care attendances [AOR = 5.02, 95% CI (2.28, 11.05)], age at
220   which the child completed vaccination [AOR = 2.54, 95% CI (1.04, 6.23)], and vaccination not
221   making the child sick [AOR = 0.32, 95% CI (0.16, 0.64)] were all significantly associated with
222   full vaccination status (**Table 3**).

223   ## Discussion

224   This study measured full vaccination coverage and associated factors among children aged 12-23

225   months in Demba Gofa District, Southern Ethiopia. In this study, only 47.0% of children were

226   fully vaccinated. BCG, OPV3, pentavalent 3, PCV3, and Rota had a similar coverage of 88.7%,

227   but measles coverage was only 59.4%, far below the others. Compared to the mini EDHS 2019

228   report, our results show slightly higher coverage (22) but equivalent coverage to results from

229   Mizan Aman town (16) and Arba Minch Zuriya District (38) in Southern Ethiopia.

230   However, our coverage was lower than those reported for North Gondar Lay Armachiho District,

231   (33) and Sinana District, Southeast Ethiopia (36). Furthermore, coverage was very low

232   compared to coverage reported for Tehulederie District, northeast Ethiopia (97%) (37), Debre

233   Markos town, Amhara regional state (92%) (9), and studies conducted in Cameroon (47) and

234   South Nigeria (23). The discrepancy may be due to differences in socioeconomic factors like

235   residence and relatively poor healthcare systems as well as the settings in which the studies were

236   conducted.

237   Different factors were examined with respect to associations with the full vaccination status.  No

238   socio-demographic characteristic was significantly associated with the full vaccination status of a

239   child. This is in contrast to other studies conducted in different parts of Ethiopia (Arbegona

240   district, South Ethiopia; Mizan Aman town, Bench Maji Zone, Southwest Ethiopia; Mecha

241   District, Northwest Ethiopia; Jigjiga district, Somali national regional state, and Addis Ababa

242   city (5, 16, 34, 35, 44)) which have shown that maternal age, maternal level of education,

243   maternal occupation, and husbands' level of education were significantly associated with full

244   vaccination coverage. A study from Bangladesh also showed that maternal age and maternal

245   level of education were significantly associated with full vaccination coverage. The possible

246   reasons for these differences may be a due to differences in the study area, other

247   sociodemographic characteristics of the participants, and the study settings.

248   We also found no associations between the children's characteristics and full vaccination

249   coverage. However, studies from Arbegona District, Southern Ethiopia; Debre Markos town,

250   Amhara regional state; Indonesia; Bangladesh; Sinana District, Southeast Ethiopia; and Addis

251   Ababa town (5, 9, 13, 26, 36, 44) all showed that age, sex, and birth order of the children were

252   significantly associated with full vaccination coverage.

253   Mothers who made healthcare decisions jointly with their husbands were 1.88 [95% CI (1.06,

254   3.34)] times more likely to vaccinate their children fully than when decisions were made by the

255   husbands alone. Furthermore, mothers who made healthcare decisions themselves were 4.03

256   [AOR 95% CI(1.66, 9.78)] times more likely to fully vaccinate their children than when

257   decisions were made by husbands alone. This is similar to a study from Indonesia (3) and

258   indicates that maternal healthcare decisions made jointly with husbands and by mothers alone

259   give mothers more freedom of health choices that benefit their children.

260   Mothers who attended post-natal care follow-up were 5.02 [AOR 95% CI (2.28, 11.05)] times

261   more likely to fully vaccinate their children than mothers who did not. This is similar to a study

262   from East-central Ethiopia (14). This may be because during postnatal care follow-up, mothers

263   have a greater chance to obtain advice on vaccinations and exposure to the service that increases

264   the probability of being fully vaccinated.

265   Respondents who replied that a child should complete vaccination by one year of age were 2.54

266   [95% CI (1.04, 6.23)] times more likely to fully vaccinate their children than those who did not

267   know the exact age of vaccination completion. This is similar to studies from the North Gonday

268   Lay Armachiho District, , Northwest Ethiopia; Ambo District, Central Ethiopia; and Addis

269   Ababa city (15, 41, 44). A possible explanation may that having better knowledge on the timing

270   of vaccination affected utilization of the service, as improved knowledge is expected to

271   positively influence the uptake and utilization of a healthcare service.

272   Mothers who responded that vaccination will not make the child sick were less likely to

273   vaccinate their children fully than those who thought that it would. Reasons given by

274   respondents who did not complete vaccination were vaccinator absenteeism, a lack of awareness,

275   time inconvenience, and not knowing the vaccination date. This was similar to a study from

276   Laelay Adiabo District, Northern Tigray, Ethiopia (15). Furthermore, feeling that the vaccination

277   had no use, a fear of side effects, religious and cultural refusals, a belief that vaccination hurts

278   the child, and a lack of awareness were reasons raised by mothers/caregivers who did not

279   vaccinate their children at all. Similar reasons have been given in other studies. (9,14,15).

280   The strength of this study are applying community-based study in a remote and rural part of the

281   country and using a simple random sampling technique. However, recall bias of mothers could

282   affect the study findings dispite the efforts made to minimize them by asking the injection site,

283   repeatitions of the shcedules, looking at the scars.Vaccine supply management, which could

284   affect vaccination uptake, was not assessed.

## Conclusions

286   Less than half of children studied here were fully vaccinated and the prevalence of unvaccinated

287   children was 11.3%, far below the government target of 90% necessary for sustained control of

288   vaccine-preventable diseases. Maternal healthcare decision-making, postnatal care attendance,

289   the objective of vaccination, the age at which a child begins and completes vaccination, and

290   sessions needed to complete vaccination were significant factors associated with full vaccination.

291   Absenteeism of vaccinators, a lack of awareness, time inconvenience, not knowing the exact date

292   of vaccination, and local religious and cultural contexts were reasons given for not fully

293   vaccinating their children.

294   We advise that district health offices continuously conduct systematic supervision and periodic

295   evaluation of vaccination performance of health facilities using a standardized checklist. Also,

296   there should be an adequate supply of vaccination cards to health facilities (health centers and

297   health posts). The health sector and other legal bodies are advised to improve maternal

298   healthcare decision-making by empowering women on decision-making processes. Promoting

299   institutional delivery and postnatal care services could improve full vaccination coverage. Health

300   extension workers should emphasize explaining the specific names of vaccine-preventable

301   diseases, the age at which a child begins and completes vaccination, and the number of sessions

302   needed to complete vaccinations. Starting with senior management and extending to health

303   extension workers, there is a need for improved planning of convenient times for the parent to

304   attend vaccination, evaluating performance among target children, estimating the frequency of

305   missed children, and providing the opportunity for re-attendance for defaulting children. The

306   vaccine supply chain should also be studied further.

307

## Acknowledgements

309  We are grateful to Wolaita Sodo University, College of Health and Medical Science, School of
310  Public Health for supporting this study. Our thanks extend to district health managers and staff
311  for their support in facilitating the research process by timely approving and writing support
312  letters. Finally, special thanks go to data collectors and study participants who contributed to this
313  study
