Background: The continuous spreading of the respiratory Coronavirus disease, COVID-19, has been a threat to global health, especially among those fighting directly against it. Nurses who work in critical care have reported very high levels of stress during these extreme circumstances. It is very important to measure the level of stress and resilience among these nurses in order to diminish further psychological distress. This study aims to assess the levels of perceived stress and resilience among critical care nurses.**Methodology:** In this correlational cross-sectional study, critical care nurses (n=139) were recruited by gatekeepers in a governmental university hospital in Riyadh city between 12 March and 8 April 2021 to complete an online questionnaire. The measurement tools used in this study were the Connor-Davidson Resilience Scale 10 (CD-RISC-10) and the Perceived Stress Scale of COVID-19 (PSS-10 items). Data were analyzed using a descriptive and inferential analysis to calculate frequencies to determine the distribution of stress and resilience, and multiple regression was applied to assess the relationship between them.**Results:**One hundred and thirty-nine critical care nurse (64%) responded. The perceived levels of stress reported were: no stress (8%; n=12), mild stress (14%; n = 21), moderate stress (38%; n = 55), high stress (22%; n = 32), and severe stress (18%; n=26). The levels of resilience reported were: very low (8%; n=11), low (18%; n = 26), moderate (42%; n = 62), and high (32%; n = 47). The level of stress and resilience reported by the majority of critical care nurses was moderate; there was no significant correlation between COVID-19-related stress and resilience among the critical care nurses. Severe levels of stress were mostly reported among critical care nurses working in the NICU and high levels of stress were reported among those working in the emergency department. The nurses reported being highly confident that they were able to handle personal epidemic related problems with a mean score of 2.36. This reflects having

a high level of resilience (42%; n=62) and was significantly associated with years of experience as a nurse (p <.0027). **Conclusion:**Although Covid-19 cases had declined significantly during the study period in Saudi Arabia, the majority of nurses were still experiencing moderate to high levels of stress about the epidemic, but were, at the same time, moderately resilient. Continued monitoring of the stress levels of this high-risk group is highly essential. Conducting more research is needed to measure the effectiveness of psychosocial support interventions.

16   **Abstract**

17   **Background:** The continuous spreading of the respiratory Coronavirus disease, COVID-19, has been

18   a threat to global health, especially among those fighting directly against it. Nurses who work in critical

19   care have reported very high levels of stress during these extreme circumstances. It is very important

20   to measure the level of stress and resilience among these nurses in order to diminish further

21   psychological distress. This study aims to assess the levels of perceived stress and resilience among

22   critical care nurses.

23   **Methodology:** In this correlational cross-sectional study, critical care nurses (n=139) were recruited by

24   gatekeepers in a governmental university hospital in Riyadh city between 12 March and 8 April 2021

25   to complete an online questionnaire. The measurement tools used in this study were the Connor-

26   Davidson Resilience Scale 10 (CD-RISC-10) and the Perceived Stress Scale of COVID-19 (PSS-10

27   items). Data were analyzed using a descriptive and inferential analysis to calculate frequencies to

28   determine the distribution of stress and resilience, and multiple regression was applied to assess the

29   relationship between them.

30   **Results:** One hundred and thirty-nine critical care nurse (64%) responded. The perceived levels of

31   stress reported were: no stress (8%; n=12), mild stress (14%; n = 21), moderate stress (38%; n = 55),

32   high stress (22%; n = 32), and severe stress (18%; n=26). The levels of resilience reported were: very

33   low (8%; n=11), low (18%; n = 26), moderate (42%; n = 62), and high (32%; n = 47). The level of

34   stress and resilience reported by the majority of critical care nurses was moderate; there was no

35   significant correlation between COVID-19-related stress and resilience among the critical care nurses.

36   Severe levels of stress were mostly reported among critical care nurses working in the NICU and high

37   levels of stress were reported among those working in the emergency department. The nurses reported

38   being highly confident that they were able to handle personal epidemic related problems with a mean

39   score of 2.36. This reflects having a high level of resilience (42%; n=62) and was significantly

40   associated with years of experience as a nurse (p <.0027).

41   **Conclusion:** Although Covid-19 cases had declined significantly during the study period in Saudi

42   Arabia, the majority of nurses were still experiencing moderate to high levels of stress about the

43   epidemic, but were, at the same time, moderately resilient. Continued monitoring of the stress levels of

44   this high-risk group is highly essential. Conducting more research is needed to measure the

45   effectiveness of psychosocial support interventions.

Introduction

48
49   The whole world was dramatically changed when the World Health Organization (WHO, 2020)

50   announced the outbreak of Novel Coronavirus Disease 2019 (COVID-19), which was originally discovered

51   in Wuhan, China (Zhu et al., 2020) and quickly spread, becoming a worldwide pandemic (Li et al., 2020).

52   COVID-19 is highly contagious and has a 2–14-day incubation period. Even during the interval between

53   suspecting and confirming a case, an infected patient might transmit the disease (Lauer et al., 2020), which

54   makes it very challenging to slow down the disease's spread. After 12 weeks of pandemic spread

55   internationally in 66 nations around the world (Arab news, 2020), the Saudi Ministry of Health (MOH)

56   declared the first case of COVID-19 in the country on March 2, 2020 (MOH, 2020). Since then, the COVID-

57   19 outbreak has expanded to over 206 cities in Saudi Arabia, infecting 3,65,099 individuals and causing

58   6,329 fatalities (Saudi Ministry of Health (MOH). Saudi authorities banned sports activities, closed

59   educational institutions, parks, and shopping centers, as well as domestic public transportation, and

60   implemented partial curfews (Yezli, & Khan, 2020; Alshammari et al., 2020). Saudi Arabia began adopting

61   early preventative measures and used one of the strictest strategies to curb the COVID-19 pandemic limiting

62   both human and economic losses (Shimul et al., 2021). These measures included: blocking international

63   borders and closing the two main mosques in Mecca and Medina to both native and foreign religious

64   visitors, closing all mosques for Friday prayers, and closing all government offices except vital service

65   providers (Mahmud & Al-Mohaimeed, 2020). A year after the initial outbreak of COVID-19, nurses were

66   still staidly set on the front line facing the extreme pressure of taking care of critically ill patients. Due to

67   their stressful workload, high level of responsibility, and complexity of care, critical care nurses experience

68   high levels of stress compared to nurses in other clinical settings even before the starting of COVID-19

69   pandemic. Emergency department nurses in India have also reported a high risk of burnout due to an

70   excessive workload and high amount of critical patient cases (Dhandapani & Cyriac, 2020).

71   Nurses tend to disregard their own interests during unforeseen natural disasters and viral outbreaks to

72   willingly participate on the front lines and also make self-sacrificing decisions out of a moral and ethical

73   responsibility (Maben et al., 2020).

74   Several Saudi studies were conducted during COVID-19 among health care providers reporting high

75   levels of stress and anxiety (Alotni et al., 2020; Mohsin et al., 2021; Aljhani et al., 2021; Alenazi et al.,

76   2020), specifically among those who were on the front lines (AlHanawi et al., 2020). During COVID-19,

77   nurses were highly affected by depression in comparison to their physician colleagues (Almutair et al.,

78   2021). According to a cross-sectional healthcare worker survey conducted in 17 countries including Saudi

79   Arabia aimed at assessing factors linked with psychological distress including fear of COVID-19 and

80   reported coping levels, physicians experienced higher psychological distress, but had a lower fear of

81   COVID-19, while nurses reported moderate to high resilient coping levels (Rahman et al., 2021). This

82   psychological distress is caused by many factors including: the high risk of infection dealing directly with

83   COVID-19 patients, witnessing numerous deaths, an overwhelming workload, shortages of protective

84   supplies, family isolation, and physical exhaustion (Nobles et al., 2020; Chew et al., 2020; Zhu et al., 2020;

85   Brooks et al., 2020). Several studies found that young age and female gender were predictive risk factors

86   of depression among healthcare workers (Mohsin et al., 2021; Slama et al., 2021). The level of depression

87   among participants aged 31–40 years old was substantially greater than the level of depression among

88   participants aged 50 and older (Almutair et al., 2021). Occupational status, number of family members, and

89   years of experience in the medical sector were all linked to burnout (Aljhani et al., 2021). However, coping

90   mechanisms were found to be more prevalent in those aged 25–34 years, females, married, and those with

91   a bachelor's degree (Natividad et al., 2021).

92   Psychological resilience refers to a person's ability to adapt to major stressors such as psychological or

93   physiological trauma, threats, tragedies, familial and relationship troubles, job stress, and financial concerns

94   (American Psychological Association, 2012). Nurses need resilience as they face multiple stressors on a

95   daily basis and have to deliver quality care to their patients under all circumstances. The rapid spread of

96   COVID-19, the increase in the number of patients hospitalized, and intensive contact with critically ill

97   patients all put critical care nurses at high risk for many psychological problems. This study adds to the

98   body of literature involving the early identification and prevalence of stress among healthcare workers and

99   their ability to adjust based on individual personality traits and psychological functions. This study is

100   essential as it assesses both the stress and resilience levels among this high-risk population.

101

102   **Materials & Methods**

103

104   This is a descriptive correlational cross-sectional quantitative study conducted among a convenience

105   sample of nurses working in critical care units. The data was collected during the COVID-19 pandemic in

106   Riyadh city, Saudi Arabia, including nurses from: the emergency room (ER), the adult intensive care unit

107   (ICU), the pediatric intensive care unit (PICU), the neonatal intensive care unit (NICU), the operating room

108   (OR), the post-anesthesia care unit (PACU), and the cardiac surgery OR (CSOR). Ethical approval was

109   granted from Princess Nourah bint Abdulrahman University to carry out the study within its facilities

110   (Ethical Application Ref: 21-0055). The participants gave informed consent to take part in the research and

111   were ensured the right to withdraw from the study. All the written informed consent forms were received

112   from all participants.

113   A total of 217 questionnaires were sent to the email addresses of critical care nurses from the research

114   unit at the selected hospital. A total of 139 critical care nurses completed the online questionnaire giving a

115   response rate of 64%.

116

117   **Data collection methods**

118   We used the Perceived Stress Scale of COVID-19 (PSS-10), which contains 10 elements (Pedrozo-

119   Pupo et al., 2020), to measure the perceived stress levels of study participants. Each element has a

120   maximum score of 4 (Always) and a minimum score of 0 (Never). Elements n. 1, 2, 3, 6, 9, and 10 are

121   scored from 0 to 4; elements n. 4, 5, 7, and 8 are scored reversely, from 4 to 0. The total assessment scores

122   range from 0 and 40: scores between 0-13 are considered to be low stress, 14-26 are considered moderate,

123   while scores equal to 27 or greater are considered high perceived stress in relation to COVID-19.

124

125   The second tool we used in this study is the Connor-Davidson Resilience Scale 10 (CD-RISC-10)

126   (Campbell-Sills et al., 2007). This scale contains 10 items and serves mainly as a measure of hardiness,

127   with items corresponding to flexibility (1, 2 and 4), sense of self-efficacy (3,4), ability to regulate emotion

128   (8,10), optimism (6 and 9) and cognitive focus/maintaining attention under stress (7). Each element is

129   scored on a five-point scale ranging from 0 to 4, with 0 indicating that the resilience statement is not at all

130   true and a score of 4 representing that the statement is true nearly all of the time. The total score is obtained

131   by adding up all 10 elements and can range from 0 to 40. Higher scores indicate higher resilience, whereas

132   lower scores indicate greater difficulty bouncing back from adversity. The lowest quartile (about 1 to 25%

133   of the population) had a score of 0-29. The second quartile (those who scored between 26 and 50 percent)

134   received scores of 30 and 32. Between 33 and 36 were scored by the third quartile (51-75 percent of the

135   population). The highest quartile (76-100 percent) had a score of 37 to 40 (Campbell-Sills et al., 2007).

136

137   **Data analysis**

138   A statistical analysis was performed using the IBM SPSS, version 22. (SPSS Inc., Chicago, IL, USA).

139   Descriptive statistics, specifically percentage, was used to determine the distribution of the respondents

140   according to their demographic profile including: age, marital status, years of work experience, and level

141   of education. Mean scores were used to determine the level of COVID-19 related stress and outlook, and

142   percentage was used to define the distribution of the level of stress experienced by the respondents.

143   Percentage was also used to determine the distribution of the respondents according to resilience level. A

144   multiple regression analysis was used to determine whether the demographic characteristics of the

145   respondents had a linear relationship to their level of COVID-19 related stress and resilience.

146

147   **Results**
148   **The demographic profile**

149   The demographic profile of the study participants, presented in Table 1, is as follows: a majority (60%)

150   were between the ages of 30 and 40, followed by ages 25-30 (27%), then 45 years and older (8%), and only

151 5% were aged 20-25. The majority (52%) of the respondents were single, and 41% were married, while

152 only 5% and 2% were divorced and widowed, respectively. Nearly half (42%) of the respondents had

153 worked in healthcare between 6 and 9 years, followed by 10-15 years (25%), 3-5 years (16%), 15+ years

154 (11%), and very few had worked less than 2 years (4%). The level of education of the respondents was

155 overwhelmingly (81%) a bachelor's degree, while only 10% were diploma graduates, and 9% had a

156 master's degree. Not one respondent had a doctoral degree. Our demographic survey also showed that

157 86.4% of the respondents took care of a patient with COVID-19.

158 **Table 1**

159

160 **Level of perceived stress during COVID-19 and its correlation to demographic profile**

161 The correlation data between stress levels and demographics (presented in Table 2) shows that the nurses

162 who were single (19.8%) had moderate levels of COVID-19 related stress and the majority of those with

163 moderate levels of stress (30.1%) were those with a bachelor's degree. The correlation between levels of

164 COVID-19 related stress of the nurses when grouped according to their years of work experience found

165 that those with less than one year of work experience had mild levels of stress while the highest number of

166 those with 1-2 years of experience (2.7%) and those with 3-5 years of experience (5.4%) both had moderate

167 levels of stress. Moderate stress levels were also the most commonly reported among those with 6-9, 10-

168 15, and more than 15 years of experiences (15%, 9.5% and 4.1% respectively). Nurses with 6-9 years of

169 work experience comprised the majority (3.4%) of those who reported no stress to very low, mild (4.1%),

170 moderate (9.5%), and high (13%) levels of stress. The highest number (9.5%) of those who reported severe

171 levels of stress were those with 10-15 years of work experience. There were also varying levels of stress

172 across the clinical area of assignments. The largest number of nurses who reported severe stress worked in

173 the NICU, and the highest number of those who reported high levels of stress worked in the ED. This shows

174 that even nurses who have not taken care of patients with COVID-19 still experience work-related stress

175 that varies from very low to severe levels.

176   Table 2 also shows the results of the predictive tests between the demographic characteristics of the

177   respondents and levels of COVID-19 related stress. The data show that age has a p value=0.4528 which is

178   greater than the alpha=0.05 which is not statistically significant and indicates strong evidence for the null

179   hypothesis. The data also show similar findings with marital status with p=0.7138; educational status with

180   p=0.2299; whether or not the respondent took care of a patient with COVID-19 with p=0.415; and clinical

181   area with a p=0.1343. All respective p values are greater than the alpha=.05 indicating non statistical

182   significance. The non-significance means that the null hypothesis is not rejected which indicates that age,

183   marital status, education status, and whether or not the nurses took care of a patient with COVID-19 do not

184   predict the level of COVID-19 related stress among the nurses.

185   **Table 2**

186

187   Table 3 below shows the level of stress reported by the specific domains of COVID-19 related

188   stress. The nurses reported being very stressed that something serious would happen unexpectedly with the

189   epidemic as shown by a mean score of 3.47. They also reported being highly stressed by the epidemic itself

190   as shown by a mean score of 3.57. The participating nurses reported being moderately stressed with the

191   inability to control the important things in their lives due to the pandemic (mean score: 3.31), the inability

192   to cope with what must be done to control possible infection (mean score: 2.91), that things related to the

193   epidemic were out of their control (mean score: 3.15), and that the difficulties accumulated during the

194   epidemic made them feel unable to overcome them (mean score: 2.96).

195   **Table 3**
196

197   Our survey results also showed the COVID-19 related positive outlook of the nurses as illustrated

198   in Table 4. The nurses were highly confident that they were able to handle personal epidemic related

199   problems with a mean score of 2.36. They reported a moderately positive outlook that things were going

200   well with the epidemic with a mean score of 2.58; a moderate positivity about feeling able to control the

201   difficulties that appeared in their lives due to the infection with a mean score of 2.72; and a moderate

202 positivity that they had everything under control in relation to the epidemic as shown by a mean score of

203 2.85.

204 **Table 4**

205 **Level of resilience**

206   The largest number of nurses (62/146 or 42%) had moderate levels of resilience with scores ranging

207 from 21-30, while 47 nurses (32%) had a high level of resilience as shown by scores ranging from 31-40.

208 There were 26 nurses (18%) who had low resilience levels; and 11 (8%) which had very low or poor

209 resilience as shown in Table 5.

210 **Table 5**

211 **Correlation between COVID-19 related stress, COVID-19 related positive outlook, and resilience**

212   Table 6 shows the correlation matrix of resilience, COVID-19 related stress and positive outlook

213 and resilience. The r (144) =0.07< t=1.976 for COVID-19 related stress and positive outlook. This r value

214 indicates that the values are not significant, hence, the null hypothesis is not rejected. This means that there

215 is negligible positive correlation between COVID-19-related stress and a positive outlook on the COVID-

216 19 pandemic.

217   Furthermore, the table also shows that the r (144) =-0.05 < t=1.976 for COVID-19-related stress

218 and resilience. This also indicates that there is a negligible negative correlation between COVID-19-related

219 stress and resilience among the nurses. The null hypothesis is therefore not rejected.

220 **Table 6**

221 **Discussion**

222 The results of this study showed that the majority of critical care nurses reported a moderate to high level

223 of COVID-19-related stress, similar to previous studies (Rahman et al., 2021; Mohsin et al., 2021; Alotni

224 et al., 2020; Crowe et al., 2020; Said et al., 2020). Our study revealed that nurses were severely stressed

225 that "something serious will happen unexpectedly with the epidemic," which indicates that nurses may have

226 been afraid that they could transmit COVID-19 to a loved one, a fear potentially exacerbated by the

227 insufficient supply of personal protective equipment (Natividad et al., 2021). Also, working at a hospital

228   that hosts COVID-19 patients, regardless of whether or not healthcare workers dealt directly with these

229   COVID-19 patients, was significantly associated with developing anxiety (Alenazi et al., 2020).

230

231   Interestingly, our results showed that the majority of nurses had a moderate to high level of resilience,

232   in line with studies done in Philippines and Saudi Arabia respectively (Labrague & Santos, 2020; Rahman

233   et al., 2021). A positive correlation was found between high levels of stress and more years of experience

234   as a nurse. This is contrary to what was stated in several studies which highlighted a connection between

235   fewer years of work experience and an increased risk of post-traumatic stress symptoms among health care

236   employees (Mohsin et al., 2020; Slama et al., 2021; Li et al.,2020). This might be due to the dependency of

237   health intuitions on those who were more qualified to take care of patients suffering from COVID-19

238   (AlJhani et al., 2021). The majority of nurses who reported high levels of stress were working in emergency

239   departments. This result seems to be consistent with other research which found that nurses who worked in

240   respiratory, emergency, infectious disease, and ICU departments were 1.4 times more likely to experience

241   fear, as well as twice as likely to experience anxiety and depression (Li et al., 2020; Zhu et al., 2020).

242   Finally, this study revealed that there is no significant correlation between COVID-19-related stress and

243   resilience, unlike the previous study (Setiawati et al., 2021). A possible explanation for these results could

244   be because of the timeframe in which the data was obtained. Our data was collected after curfew ended in

245   Saudi Arabia and COVID-19 cases had significantly declined due to affective vaccine campaigns and

246   following WHO precautions (Shimul et al., 2021). It is possible that at this point in the pandemic, the stress

247   levels of healthcare workers declined, and resilience levels started to increase due to the successful

248   implementation of governmental health protocols.

249   **Recommendations**

250   We propose the following recommendations based on the findings of our study: We suggest further

251   studies on critical care nurses paired with psychological consultations. We also recommend that

252   administrators report every six months on the stress levels of staff nurses and decide, based on the results,

253   what interventions should be pursued. Finally, we suggest preparing workshops for nurses to help enhance

254   psychological resilience.

255   **Limitations**

256   One of the limitations of this study was a low response rate due to the unavailability of critical care nurses.

257   These nurses lacked the time to fill out the questionnaire because of the overwhelming workload in their

258   units.

259

260   **Implications for practice**

261
262   -Provide a psychologist to each nursing team for early psychological assessment and intervention.
263
264   -Assign appropriate patients based on nursing ability and provide any additional training required.
265
266   -Educate nurses about the safe usage of protective equipment, waste management, and
267   sterilization.
268
269   - Ensure nurses get enough rest and are not overloaded with work.
270

271   **Conclusions**

272   In conclusion, this study has shown the effect of the COVID-19 pandemic on the mental wellbeing of

273   critical care nurses. Our study found a moderate level of stress and resilience among the nurses involved in

274   the study. There was also no correlation between stress and resilience. The evidence from this study suggest

275   that the mental health status of nurses working in critical care matters, and we recommend that psycho-

276   social support services be available to those at high risk of stress. More research is also needed to determine

277   the factors affecting the levels of stress and resilience among critical care nurses.

Level of stress related to specific domains of COVID-19 related stress

1 **Table 3**

2 *Level of stress related to specific domains of COVID-19 related stress*

Covid-19 related Stress Domains	n	SD	Mean Score	Level of Stress
"I have felt affected as if something serious will happen unexpectedly with the epidemic"	146	1.15	3.47	Severe
"I have felt that I am unable to control the important things in my life due to the epidemic"	146	1.23	3.31	Moderate
"I have been nervous or stressed by the epidemic"	146	1.02	3.57	High
"I have felt unable to cope with the things I have to do to control the possible infection"	146	1.18	2.91	Moderate
"I have been upset that things related to the epidemic are out of my control"	146	1.18	3.15	Moderate
"I have felt that the difficulties accumulate in these days of the epidemic and I feel unable to overcome them"	146	1.15	2.96	Moderate

COVID-19 related positive outlook of the nurses

1 **Table 4**

2 *COVID-19 related positive outlook of the nurses*

Covid-19 related Positive Outlook	n	SD	Mean score	Level of Positivity
"I have been confident about my ability to handle my personal epidemic related problems"	146	.90	2.36	High
"I have felt that things are going well (optimistic) with the epidemic"	146	1.12	2.58	Moderate
"I have felt that I can control the difficulties that could appear in my life due to the infection"	146	1.04	2.72	Moderate
"I have felt that I have everything under control in relation to the epidemic"	146	1.02	2.85	Moderate

Level of Resilience of the Nurses

1   **Table 5**

2   *Level of Resilience of the Nurses*

Mean Scale	Level of Resilience	Frequency	Percentage
0-10	Very Low	11	8
11-20	Low	26	18
21-30	Moderate	62	42
31-40	High	47	32
		n=146	100%

Correlation Matrix (Covid-19 Related Stress, COVID-19 related Positive outlook, Resilience)

1   **Table 6**

2   *Correlation Matrix (Covid-19 Related Stress, COVID-19 related Positive outlook, Resilience)*

					Covid-19 Related Stress	
	r	df	alpha	Critical value	Significance	
Covid-19 related positive outlook	0.07	144	.05	1.976	negligible correlation	positive
Resilience	-.05				negligible correlation	negative

3   *The correlation is significant at* ***The P-Value is < .01;*** *p < .05 (two-tailed); Correlation Matrix*

4   *(Covid-19 Related Stress, COVID-19 related Positive outlook, Resilience)*
