Evaluation of nutritional and economic feed values of spent coffee grounds and *Artemisia princeps* residues as a ruminant feed using *in vitro* ruminal fermentation

Jakyeom Seo, Jae Keun Jung, Seongwon Seo

Much research on animal feed has focused on finding alternative feed ingredients that can replace conventional ones (e.g., grains and beans) to reduce feed costs. The objective of this study was to evaluate the economic, as well as nutritional value of spent coffee grounds (SCG) and Japanese mugwort (*Artemisia princeps*) residues (APR) as alternative feed ingredients for ruminants. We also investigated whether pre-fermentation using *Lactobacillus* spp*.* was a feasible way to increase the feed value of these by-products. Chemical analyses and an *in vitro* study were conducted for SCG, APR, and their pre-fermented forms. All the experimental diets for *in vitro* ruminal fermentation were formulated to contain a similar composition of crude protein, neutral detergent fiber and total digestible nutrients at 1x maintenance feed intake based on the dairy National Research Council (NRC). The control diet was composed of ryegrass, corn, soybean meal, whereas the treatments consisted of SCG, SCG fermented with *Lactobacillus* spp*.* (FSCG), APR, and its fermented form (FAPR). The treatment diets replaced 100 g/kg dry matter (DM) of the feed ingredients in the control. Costs were lower for the all treatments, except FAPR, than that of the control. After 24-h incubation, the NDF digestibility of the diets containing SCG and its fermented form were significantly lower than those of the other diets ($P < 0.01$); pre-fermentation tended to increase NDF digestibility ($P = 0.07$), especially for APR. Supplementation of SCG significantly decreased total gas production (ml/g DM) after 24-h fermentation in comparison with the control ($P < 0.05$); however, there were no significant differences between the control and the SCG or the APR diets in total gas production, as expressed per Korean Won (KRW). Diets supplemented with SCG or FSCG tended to have a higher total volatile fatty acid (VFA) concentration, expressed as per KRW, compared with the control ($P = 0.06$). Conversely, the fermentation process of SCG and APR significantly decreased total gas production and VFA production as expressed per KRW ($P < 0.05$). Because of their nutrient composition and relatively lower cost, we concluded that SCG and APR could be used as alternative feed sources, replacing conventional feed ingredients. However, pre-fermentation of agricultural by-products, such as SCG and APR, may be inappropriate for improving their nutritive considering the

increase in production costs.

25   **Abstract**

26   Much research on animal feed has focused on finding alternative feed ingredients that can

27   replace conventional ones (e.g., grains and beans) to reduce feed costs. The objective of this

28   study was to evaluate the economic, as well as nutritional value of spent coffee grounds (SCG)

29   and Japanese mugwort (*Artemisia princeps*) residues (APR) as alternative feed ingredients for

30   ruminants. We also investigated whether pre-fermentation using *Lactobacillus* spp. was a

31   feasible way to increase the feed value of these by-products. Chemical analyses and an *in vitro*

32   study were conducted for SCG, APR, and their pre-fermented forms. All the experimental diets

33   for *in vitro* ruminal fermentation were formulated to contain a similar composition of crude

34   protein, neutral detergent fiber (NDF) and total digestible nutrients at 1x maintenance feed intake

35   based on the dairy National Research Council (NRC). The control diet was composed of

36   ryegrass, corn, soybean meal, whereas the treatments consisted of SCG, SCG fermented with

37   *Lactobacillus* spp. (FSCG), APR, and its fermented form (FAPR). The treatment diets replaced

38   100 g/kg dry matter (DM) of the feed ingredients in the control. Costs were lower for the all

39   treatments, except FAPR, than that of the control. After 24 hour (h) incubation, the NDF

40   digestibility of the diets containing SCG and its fermented form were significantly lower than

41   those of the other diets ($P < 0.01$); pre-fermentation tended to increase NDF digestibility ($P =$

42   0.07), especially for APR. Supplementation of SCG significantly decreased total gas production

43   (ml/g DM) after 24 h fermentation in comparison with the control ($P < 0.05$); however, there

44   were no significant differences between the control and the SCG or the APR diets in total gas

45   production, as expressed per Korean Won (KRW). Diets supplemented with SCG or FSCG

46   tended to have a higher total volatile fatty acid (VFA) concentration, expressed as per KRW,

47   compared with the control ($P = 0.06$). Conversely, the fermentation process of SCG and APR

48 significantly decreased total gas production and VFA production as expressed per KRW ($P <$

49 0.05). Because of their nutrient composition and relatively lower cost, we concluded that SCG

50 and APR could be used as alternative feed sources, replacing conventional feed ingredients.

51 However, pre-fermentation of agricultural by-products, such as SCG and APR, may be

52 inappropriate for improving their nutritive considering the increase in production costs.

53

54 **1. Introduction**

55   Research on animal feed has often focused on finding alternative feed ingredients to replace

56 conventional ones (e.g., grains and beans) in order to reduce feed costs. This is most important in

57 developing countries where the supplies of cereal grains and beans are not great enough to

58 support even the human population. Historically, by-products from processing crops and food

59 products have received much attention as feed alternatives because of their consistent and mass

60 production. Food by-products would also likely be inexpensive because of their classification as

61 a waste product. Many by-products, however, do not contain enough nutrients to support

62 livestock requirements, and their palatability and digestibility would need to be enhanced, even

63 for ruminants. Pre-fermentation of these by-products by bacteria (Kim et al., 2012), yeast

64 (Wanapat et al., 2011), or fungi (Salman et al., 2008) are common methods to enhance their

65 nutritional value (see Mahesh and Mohini [2013] for a review).

66   Although fermentation may improve the nutritional quality of the by-products, and it is an

67 environmentally sustainable practice, it will increase the cost for feed production. This additional

68 cost is often ignored by researchers. To make the fermentation process feasible, the production

69 costs of a fermented by-product must to be competitive with conventional feed ingredients

70 (Wanapat et al., 2013). Therefore, the economic value, as well as nutritional value, of fermented

71 by-products must be considered simultaneously.

72   In this study, we evaluated the economic and nutritional values of spent coffee grounds

73 (SCG) and Japanese mugwort (*Artemisia princeps*) residues (APR), as well as their fermented

74 products as potentially cost-effective feed ingredients for ruminants. An *in vitro* ruminal

75 fermentation study where Total mixed rations (TMR) was supplemented with SCG or APR was

76 conducted. These by-products were chosen primarily because of the rapid increase of production,

77 and the relatively high content of nutrients and bio-active compounds. SCG are generated during

78 the manufacture of instant coffee. It is the residue that remains after brewing raw coffee powders

79 with hot water or steam. Annually, 6-million tons of SCG are produced worldwide and most of it

80 is burned as waste, resulting in greenhouse gas emissions (Tokimoto et al., 2005). There have

81 been studies on the potential of SCG as a feed source for ruminants (Campbell et al., 1976;

82 Bartley et al., 1978; Givens and Barber, 1986; Xu et al., 2007) and even for monogastric animals

83 (Sikka et al., 1985; Sikka and Chawla, 1986). Xu et al. (2007) concluded that wet coffee grounds

84 could be included up to 100 g/kg on a dry matter (DM) basis in total mixed rations (TMR) for

85 goats. APR is a by-product from the traditional Korean medicine industry; it is produced during

86 harvesting and processing of leaves. Positive effects were observed in growth performance of

87 broilers supplemented by *Lactobacillus*-fermented APR (Kim et al., 2012). To the best of our

88 knowledge, however, there has been no attempt to assess the feasibility of fermented SCG or

89 APR as a feed alternative in ruminants based on both their nutritional and economic values.

90

91

92 **2. Materials and methods**

93   Two cannulated non-lactating Holstein cows at Center for Animal Science Research, Chungnam

94   National University, Korea were used in this study. Animal use and the protocols for this

95   experiment were reviewed and approved by the Chungnam National University Animal Research

96   Ethics Committee (CNU-00455).

97

98   *2.1. Preparation of experimental diets*

99   The feed ingredients used in this study were ryegrass, corn, soy bean meal (SBM), SCG,

100   APR, and the *Lactobacillus*-fermented forms of SCG and APR (FSCG and FAPR, respectively).

101   SCG were purchased from an instant coffee manufacturer (Dongseo Food, Inc., Bupyeong,

102   Korea), and APR was obtained from the Ganghwa Agricultural R&D Center (Incheon, Korea).

103   The fermentation process for SCG and APR with *Lactobacillus* spp. was conducted as described

104   by Kim et al. (2012). Briefly, four strains of *Lactobacillus* spp. (*L. acidophilus* ATCC 496, *L.*

105   *fermentum* ATCC 1493 [American Type Culture Collection: Virginia, USA], *L. plantarum*

106   KCTC 1048 [Korean Collection Type Culture, Daejeon, Korea], and *L. casei* IFO 3533 [Korea

107   Food Research Institute, Daejeon, Korea]) were used to ferment SCG and APR. A 1l culture

108   medium was inoculated with a 2 ml aliquot containing 10^9 cfu/ml of each *Lactobacillus* strain

109   (de Man, Rogosa, and Sharpe broth [Difco Laboratories, Francisco Soria Melquizo S.A., Madrid,

110   Spain], 10 g; sucrose, 10 g) and incubated at 36ºC for 24 hour (h). Next, 4 kg of dried SCG and

111   APR were mixed with 400 ml of prepared *Lactobacillus* inoculum in a fermentation flask and

112   incubated for 72 h at 36ºC. The fermented by-products were obtained after freeze-drying the

113   cultured substrate and media for 2 days following the manufacture's recommendations

114   (ilShinBioBase, Inc., Korea).

115   All of the diets that included *in vitro* fermentation were formulated to meet nutrient

116   requirements for non-lactating dairy cows (total digestible nutrient at 1x maintenance feed intake

117   [TDN1x], 680 g/kg; crude protein [CP], 120 g/kg; neutral detergent fiber [NDF], 420 g/kg on a

118   DM basis) according to the National Research Council (NRC 2001). The control diet was

119   composed of 500 g/kg of ryegrass and 500 g/kg of a corn and SBM mix. The four experimental

120   diets (SCG, FSCG, APR, and FAPR) were formulated to contain TDN1x, CP, and NDF contents

121   (g/kg DM) similar to the control, replacing original ingredients with 100 g/kg DM of SCG,

122   FSCG, APR or FAPR, respectively.

123

124   *2.2. In vitro incubation*

125   Rumen fluid was collected before the morning feeding from two cannulated non-lactating

126   Holstein cows fed a ration consisting of 600 g/kg timothy hay and 400 g/kg of a commercial

127   concentrate mix (123 ± 8.8 g/kg CP, 35 ± 6.4 g/kg ether extract [EE], 265 ± 6.9 g/kg NDF, and

128   109 ± 1.2 g/kg ash) twice daily at the Center for Animal Science Research, Chungnam National

129   University, Korea. The rumen contents were mixed and transferred into a thermos bottle, and

130   immediately transported to the laboratory. Rumen contents were strained through 4 layers of

131   cheesecloth and mixed with 4x volumes of *in vitro* rumen buffer solution (Goering and Van

132   Soest, 1970) under strictly anaerobic conditions. Fifty ml of rumen fluid/buffer mixture was

133   transferred into 125 ml serum bottles containing 0.5 g of experimental diets under continuous

134   flushing with O_2-free CO_2 gas. The bottles were sealed with butyl rubber stoppers and aluminum

135   caps, and incubated for 0, 3, 6, 9, 12, 24, and 48 h at 39°C.

136

137

138 *2.3. Analyses*

139   Contents of DM (#934.01), CP (#976.05), EE (#920.39), lignin (ADL; #973.18) and ash

140 (#942.05) in the feed samples were determined as described by AOAC (2005). NDF, analyzed

141 using a heat stable amylase and expressed inclusive of residual ash, and acid detergent fiber

142 (ADF) were determined as described by Van Soest et al. (1991). Neutral detergent insoluble

143 crude protein (NDICP) and acid detergent insoluble crude protein (ADICP) were determined as

144 described by Licitra et al. (1996). Non-fiber carbohydrate (NFC) was calculated as 1000-CP-EE-

145 Ash-(NDF-NDICP) based on NRC (2001).

146   For phenolic acid analysis, caffeic acid, *p*-coumaric acid, ferulic acid, and sinapic acid

147 (Sigma-Aldrich, Missouri, USA; # C0625, # C9008, # 12870, and # D7927, respectively) were

148 used as standards. Identification of phenolic acids in the SCG and APR samples was based

149 primarily on retention time, UV spectra obtained from high-performance liquid chromatography

150 (HPLC-DAD), and mass spectrometric data using authentic standards. Phenolic acids were

151 analyzed as described by Rochfort et al. (2006).

152   After each incubation period, total gas production was measured using a pressure transducer

153 (Sun Bee Instruments, Inc., Seoul, Korea) as described by Theodorou et al. (1994). Next, 5 ml of

154 head space gas was collected using a gas tight syringe (Hamilton, Reno, Nevada, USA) for

155 analysis of CH_4 using a gas chromatograph (Daesung Science IGC-7200, Seoul, Korea) equipped

156 with a thermal conductivity detector and HayeSep Q 80/100 column (Restek, Bellefonte,

157 Pennsylvanian, US). The pH of the cultured fluid was measured with a general purpose pH meter

158 (Istek Inc., Seoul, Korea). The cultured fluid was then centrifuged at 14,000 rpm for 10 min at

159 4°C, and the supernatant was used for the analyses of volatile fatty acid (VFA) and ammonia

160 concentrations. The remaining undegraded samples and fluid were analyzed for NDF using a

161 modified version of the micro-NDF method proposed by Pell and Schofield (1993) for

162 measuring NDF degradability. VFA concentrations were determined as described by Erwin et al.

163 (1961). Ammonia concentration was analyzed by the method of Chaney and Marbach (1962).

164   For the economic analysis, the price of each feed ingredient was estimated and expressed in

165 Korean won (KRW). The average market prices of ryegrass, corn, and SBM in 2009 were used

166 (i.e., 364, 317, and 660 KRW/kg DM, respectively). The prices of SCG and APR (i.e., 91 and

167 235 KRW/kg DM, respectively) were obtained from the respective manufacturers. Prices of

168 FSCG and FAPR (i.e., 270 and 429 KRW/kg DM, respectively) were calculated by adding SCG

169 and APR prices to the cost for the fermentation process (i.e., 200 KRW/kg as fed). The cost of

170 the fermentation process included expenses for microbial strains, culture medium, labor, use of

171 fermenter instruments, and manufacturing.

172

173 *2.4. Statistical analysis*

174   The experiment was conducted using a completely randomized design, and the data were

175 analyzed using the GLM procedure of SAS (SAS Institute Inc., Carey, North Carolina, USA) as:

176         $y_{ij} = \mu + \tau_i + e_{ij}$

177 Where: y_{ij} is the *j*th observation in the *i*th treatment, μ is the overall mean, τ_i is the fixed effect of

178 the *i*th treatment (i = 1 to 5), and e_{ij} is the unexplained random effect on the *j*th observation in

179 the *i*th treatment. Four contrasts were tested: the difference between the control and SCG

180 (control *versus* SCG and FSCG), control and APR (control *versus* APR and FAPR), SCG and

181 APR (SCG and FSCG *versus* APR and FAPR), and non-fermented and fermented groups (SCG

182 and APR *versus* FSCG and FAPR). Differences among treatments were also compared with the

183   Tukey's test when there was a significant overall treatment effect. Statistical significance was

184   defined as $P < 0.05$, and a trend was discussed at $0.05 \leq P < 0.10$.

185

186   **3. Results**

187   Both by-products had higher amounts of fiber and lower NFC compared with corn or SBM,

188   and SCG had a markedly high level (>100 g/kg DM) of EE (Table 1). Phenolic acid contents of

189   SCG and APR were 3.22 and 2.80 mg/g DM, respectively. More specifically, the concentrations

190   of caffeic acid, *p*-coumaric acid, ferulic acid, and sinapic acid were 1.07, 0.42, 1.70, and 0.04

191   mg/g DM and 1.72, 0.77, 0.32, and 0.00 in SCG and APR, respectively. The fermentation

192   process increased feed cost and decreased NFC contents in both by-products (Table 1). The

193   fermentation process also increased NDF content.

194   All the experimental diets for the *in vitro* fermentation contained similar TDN1x (677-683

195   g/kg DM), CP (120 g/kg DM), and NDF (423-444 g/kg DM) contents (Table 2), and their prices

196   were calculated based on the prices of each feed ingredient (Table 1) and the formulated ratio of

197   respective treatments (Table 2). The Korea Won was the unit to estimate cost of experimental

198   diets. Compared to the control diet, inclusion of the by-products reduced the price of formulated

199   diet (14–30 KRW/kg DM), except for FAPR which increased the price by 4 KRW/kg DM (Table

200   2). The use of fermented by-products increased the cost of diets by 6 to 20 KRW/kg DM.

201   Supplementation of APR or FAPR significantly reduced pH compared to other treatments (P

202   < 0.01, Table 3). Ammonia nitrogen concentration did not differ among treatments. NDF

203   digestibility of the SCG group was significantly lower than that of the other diets ($P < 0.01$) and

204   the fermentation process tended to increase NDF digestibility ($P = 0.07$), especially that of APR

205   ($P < 0.05$, Table 3). Compared to the control diet, supplementation of SCG significantly

206 decreased total gas production (ml/g DM) after 24 h fermentation ($P < 0.05$, Table 3). The

207 fermentation process of SCG and APR tended to decrease total gas production ($P = 0.10$) and

208 significantly decreased total gas production per KRW (ml/KRW). No statistical difference in

209 CH_4 production (ml/g DM) was observed among treatments; however, there was a tendency for a

210 decrease in CH_4 production with SCG supplementation as compared to that of APR ($P = 0.07$).

211 Significant differences were not detected in total VFA production (mmol/g DM), proportion of

212 acetate (mmol/mol), proportion of propionate (mmol/mol), or acetate:propionate ratio. The diet

213 supplemented with SCG or FSCG; however, tended to have a higher total VFA concentration per

214 KRW (mmol/KRW) compared to the control ($P = 0.06$). Moreover, the fermentation process of

215 SCG and APR significantly decreased total VFA production (mmol/KRW) ($P < 0.05$). There

216 were significant differences among the experimental diets in the proportion of butyrate ($P < 0.01$,

217 Table 3).

218

219 **4. Discussion**

220   This study was designed to evaluate the nutritional and economic value of two food by-

221 products, SCG and APR, as alternatives to conventional feed ingredients, and to investigate

222 whether the pre-fermentation of these by-products using *Lactobacillus* spp. could be an

223 economically feasible practice for increasing their nutritional value. These by-products were

224 chosen primarily because of the rapid increase in their production, and their relatively high

225 content of nutrients and bio-active compounds (Wallace, 2007; Acevedo et al., 2013). It was

226 expected that the bio-active phenolic compounds contained in these by-products would modulate

227 rumen microbial activity, fermentation characteristics, and CH_4 emission (Acevedo et al., 2013;

228 Kim et al., 2013). Fermentation of selected by-products using *Lactobacillus* spp. was applied to

229   improve their nutritive values as feed ingredients. However, a dramatic increase of CP by

230   microbial proliferation was not observed in either fermented by-products (Table 1), indicating

231   that phenolic compounds, such as tannins, appear to be resistant to cell wall degradation by

232   microbial inoculants. The decrease in NFC contents observed in fermented by-products (Table 1)

233   indicated that the inoculated microbes might utilize non fiber sugars in both by-products during

234   fermentation period. Both NDICP and ADICP contents were high in SCG, which might be

235   caused by the Maillard reaction that occurs during beverage production under high temperature

236   (Senevirathne et al., 2012).

237   The use of SCG and APR could decrease the price of diets with similar nutrient contents.

238   Formulated experimental diets using SCG, FSCG, and APR had lower feed cost than the control

239   diet without compromising CP, NDF, or TDN1x contents; however, the experimental diet using

240   FAPR did not (Table 2). This result suggested that the residues (except those of FAPR) may be

241   applied to feed formulation to achieve economic advantages; however, lower NFC and higher EE

242   contents observed in diets having SCG compared to the control diet should be considered when

243   SCG is applied to practical feed formulation. The supplementation fat source can increase energy

244   density in diets but the excessive fat addition limits rumen fermentation, intestinal nutrients

245   absorption (Palmquist, 1994). Because of different nutrient compositions between SCG and

246   APR, SCG tends to replace energy and protein sources, whereas APR replaces forage. Thus,

247   supplementation of SCG is more favorable when the price of protein sources is high, whereas

248   APR would be a more appropriate alternative when the price of forage is high. Both SCG and

249   APR are feed ingredient alternatives for ruminants, particularly if the goal is to reduce feed cost.

250   Total gas and VFA production after 24 h of *in vitro* fermentation were investigated to figure

251   out whether both SCG and APR can be alternative feed ingredients in nutritional and economical

252   aspects. Lower gas production observed in SCG treatments than that of the control could have

253   been caused by lower NFC contents compared to the control diet, although they had similar

254   composition in regard to CP, NDF, and TDN1x. Seo et al. (2009) reported that total gas

255   production at 48 h was primarily determined by the NFC content. The diets containing SCG had

256   significantly lower NDF digestibility than the other diets. It was speculated that such phenolic

257   compounds and resistance factors from the Maillard reaction in SCG might be associated with *in*

258   *vitro* digestibility (Puchala et al., 2005; Senevirathne et al., 2012). More importantly, there was

259   no significant difference between the control and the SCG supplemented diets in gas production

260   as expressed by ml/KRW, which implied replacement of conventional feed ingredients by SCG

261   could be economically beneficial without compromising ruminal fermentation.

262   Regarding VFA concentration, diets using APR exhibited a tendency toward increased VFA

263   production at 24 h fermentation compared to SCG (Table 3). Meanwhile, VFA production based

264   on price (mmol/KRW) tended to be higher in samples using SCG than the control group,

265   indicating the use of SCG as the alternative feed source might not cause any negative effects on

266   rumen fermentation. Xu et al. (2007) indicated that the proportion of SCG in TMR should not

267   exceed 10% of DM. Lower nutrient digestibility and VFA production were observed when 20%

268   of SCG was added to TMR in their study. However, since nutrient composition between

269   treatments was not controlled in their studies, the optimal concentration of SCG that could be

270   included in ruminant diets should be tested in terms of both nutritional and economical aspects as

271   described in this study.

272   Based on the results from *in vitro* ruminal fermentation, the pre-fermentation process in this

273   study is unlikely a feasible practice to improve the nutritional value of SCG and APR. Although

274   pre-fermentation increased NDF digestibility of APR, there was a significant decrease in VFA

275   production in fermented treatments when expressed based on costs (mmol/KRW). A declining

276   tendency in total gas production was also observed in the pre-fermentation of the by-products.

277   This implies that fermented by-products may not be appropriate as feed alternatives in terms of

278   cost-effectiveness, even though they have a potential to be a feed additive having probiotic

279   functions that include modulation of ruminal fermentation, enhanced fiber digestion, and

280   immune stimulation in the hind-gut (McAllister et al., 2011).

281   A previous *in vitro* study using beverage residues found that TMR using SCG had similar

282   CH_4 production to the control, whereas, both TMRs showed significantly decreased CH_4

283   production compared to the other TMR using green tea residues (Senevirathne et al., 2012). In

284   this study, CH_4 production was numerically decreased in the diet formulated with SCG compared

285   to the control; nevertheless, further research to investigate the effect of SCG usage on rumen

286   fermentation is required because it might have considerable amounts of polyphenolic compounds

287   that can modulate CH_4 emission (Puchala et al., 2005), nitrogen metabolism, and the rumen

288   protozoal population (Wallace, 2007).

289

290   **5. Conclusions**

291   The results of this study indicated that SCG and APR may be used as alternatives to

292   conventional feed ingredients because of their nutrient composition and relatively low cost. Pre-

293   fermentation of these products, however, may be inappropriate for improving their nutritional

294   content considering the increase in production costs. Further studies on *in vivo* ruminal

295   fermentation, and whole body digestion and metabolism by supplementing these by-products are

296   warranted.
