A fourth species of the genus *Rhonciscus* (Lutjaniformes: Haemulidae) is described from various specimens collected by small-scale fishers from the insular upper slope of western Puerto Rico. The new species was molecularly recovered as sister to the eastern Pacific *R. branickii*, to which it bears many morphological similarities. It is distinguished from other *Rhonciscus* species by the number of scale rows between the dorsal fin and the lateral line (7), larger and thus fewer scales along the lateral line (48–50), large eyes (9.4–10.4 times in SL), longer caudal peduncle (15.2–20% of SL), larger sized penultimate (14.7–19.1 % in SL) and last (7.4–9.5 % in SL) dorsal fin spine which translates to a less deeply notched dorsal fin, and its opalescent silver with golden specks live coloration. This grunt, only now recognized by ichthyologists, but well known by local fishers that target snappers and groupers between 200 and 500 m in depth, occurs in far deeper waters than any western Atlantic grunt.

18

19 **Abstract**

20 A fourth species of the genus *Rhonciscus* (Lutjaniformes: Haemulidae) is described from various
21 specimens collected by small-scale fishers from the insular upper slope of western Puerto Rico.
22 The new species was molecularly recovered as sister to the eastern Pacific *R. branickii*, to which
23 it bears many morphological similarities. It is distinguished from other *Rhonciscus* species by the
24 number of scale rows between the dorsal fin and the lateral line (7), larger and thus fewer scales
25 along the lateral line (48–50), large eyes (9.4–10.4 times in SL), longer caudal peduncle (15.2–
26 20% of SL), larger sized penultimate (14.7–19.1 % in SL) and last (7.4–9.5 % in SL) dorsal fin
27 spine which translates to a less deeply notched dorsal fin, and its opalescent silver with golden
28 specks live coloration. This grunt, only now recognized by ichthyologists, but well known by
29 local fishers that target snappers and groupers between 200 and 500 m in depth, occurs in far
30 deeper waters than any western Atlantic grunt.

31

32 **Introduction**

33 The family Haemulidae (together with the snappers, Lutjanidae) is one of the two clades grouped
34 in the order Lutjaniformes Bleeker (*Betancur-R. et al., 2017*), a tropical lineage that includes
35 commercially important shore fishes. The number of recognized grunt species in two recent
36 checklists varies between 134 and 136, grouped into two subfamilies (*Nelson, Grande & Wilson,*
37 *2016; Fricke, Eschmeyer & Fong, 2021*). Approximately 62 species of the subfamily
38 Haemulinae inhabit New World waters, with the subfamily Plectorhinchinae restricted to African

39 shores and to the Indian and western Pacific Oceans. The most recent revision by *Tavera, Acero*
40 *& Wainwright (2018)* recognized 15 New World haemulid genera.
41 The genus *Pomadasys* Lacepède, 1802 (type species *Sciaena argentea* Forsskål, 1775) included
42 several loosely related species from tropical and temperate seas. Species in this polyphyletic
43 assemblage exhibit color and morphological convergence which has resulted in several of them
44 being uncritically assigned to *Pomadasys* (*Tavera et al., 2012*). This genus was split into at least
45 five lineages widely spread throughout the family phylogeny, one of which became the genus
46 *Rhonciscus* (*Tavera, Acero & Wainwright, 2018*). Further revision is needed to clarify the
47 systematics and taxonomy of the *Pomadasys* (*sensu lato*) polyphyletic assemblage.
48 As for the New World species, Jordan & Evermann (1896) described two genera, *Rhencus* (type
49 species *Pristipoma panamense* Steindachner, 1876) and *Rhonciscus* (type species *Pristipoma*
50 *crocro* Cuvier 1830). These two genera were considered junior synonyms of *Pomadasys* until
51 *Tavera, Acero & Wainwright (2018)* resurrected them. The genus *Rhonciscus* comprises rather
52 elongate species found in marine and brackish waters, but also in rivers and freshwater streams.
53 It presently includes three species, *R. crocro*, distributed from southern Florida (USA) to at least
54 Rio de Janeiro (Brazil), in the western Atlantic (WA), and two Eastern Pacific (EP) species: *R.*
55 *branickii* (Steindachner, 1879) from southern Baja California (Mexico) to Paita (Perú), and *R.*
56 *bayanus* (Jordan & Evermann, 1898) from Mazatlán (Mexico) to Rio Tumbes, Perú. Both *R.*
57 *crocro* and *R. bayanus* can be found in freshwater rivers or streams flowing into the ocean. A
58 fourth, unrecognized *Rhonciscus* species is described based on 14 specimens captured by fishers
59 off the west coast of Puerto Rico, WA.

60

61 **Materials & Methods**

62 **Data collection and analysis**

63 In May 2017 two specimens were collected by the same fisherman from the insular upper slope
64 (280–360 m) off the west coast of Puerto Rico (Tres Cerros, Rincón; 18°20'39'' N; 67°17'00''
65 W). Both grunts were caught incidentally on hooks at the end of buoyed vertical line gear,
66 locally known as *cala con boya*, used by the deep-water, small-scale artisanal fleet. The
67 specimens were deposited at the ichthyology collections of the Sam Noble Museum of Natural
68 History of the University of Oklahoma (Norman, OK, USA) and the Florida Museum of Natural
69 History of the University of Florida (Gainesville, FL, USA). Institutional abbreviations follow
70 Sabaj (2019). Twelve additional specimens were caught in August 2019 by another fisher with
71 Antillean fish traps deployed between 200 and 250 m in depth, approximately 5 km west of the
72 mouth of the Rio Grande de Añasco river (Figure 1). Counts and measurements follow *Bussing*
73 *(1993)* and *Rocha & Rosa (1999)*. Measurements were made with calipers and recorded to the
74 nearest 0.1 mm and are presented also as percentage of standard length (SL) in Table 1.
75 Information on other *Rhonciscus* species is included in Table 2 for comparison.
76 Tissue samples were taken from the pectoral fin of the holotype and paratype specimens and
77 stored in 96% EtOH. Molecular information is provided as additional evidence of the
78 evolutionary distinction of this new taxon. DNA extraction and COI PCR amplification details

79 can be seen in (Tavera *et al.*, 2012). Sequencing was performed in one direction on an ABI 3100
80 automated sequencer (Applied Biosystems, Foster City, CA). The sequences available in
81 GenBank for all species of the genus *Rhonciscus* plus *Haemulon sciurus* (outgroup) were used
82 for molecular comparisons and a preliminary phylogenetic reconstruction. GenBank accession
83 numbers are as follows: *R. bayanus* MF446583; *R. branickii* JQ741307, JQ741308, MF956957,
84 HQ676794; *R. crocro* JQ741309; and *H. sciurus* EU697541. COI sequences were cleaned and
85 trimmed with Geneious 9.1.8 (Kearse *et al.*, 2012) and Muscle (Edgar, 2004) was used as the
86 alignment algorithm with default parameters. Phylogenetic relationships were assessed using
87 Maximum Likelihood (ML) method. Five independent runs with a random starting tree,
88 GTRGamma model of nucleotide substitution, 1000 Bootstrap analysis and search for the best
89 scoring ML tree were performed with RAxML GUI 0.93 (Silvestro & Michalak, 2012;
90 Stamatakis, 2014). Corrected intraspecific and interspecific genetic distances were calculated for
91 all available sequences.

92

93 **Ethical approval**

94 “All applicable international, national, and/or institutional guidelines for the care and use of
95 animals were strictly followed. All animal sample collection protocols complied with the current
96 laws of Puerto Rico.” Specimens were collected under the authorization of the Puerto Rico
97 Department of Natural and Environmental Resources research permit # 2017-IC-031 granted to
98 M. Schärer.

114 Opalescent Grunt

115 (Spanish name: *Ronco opalescente*)

116 Figures 2 to 5

117

118 **Holotype.** OMNH 86864, 266 mm SL. Tres Cerros, Rincón, Puerto Rico, 18.34433 °N;

119 67.28343 °W. Collected with hook and line at 280 m depth. May 1, 2017.

120

121 **Paratype.** UF 242681, 305 mm SL. Tres Cerros, Rincón, Puerto Rico,

122 18.34433 °N; 67.28343 °W. Collected with hook and line at 360 m depth. May 5, 2017.

123

124 **Diagnosis.** A species of the genus *Rhonciscus* with XIII, 12 (total 25) dorsal-fin rays; anal-fin
125 rays III, 7; pectoral-fin rays 15-16, 17(1); rather elongate body, maximum depth 32–37.4% SL;
126 convex predorsal profile; eye large, its diameter 9.4 to 10.4 % SL; snout subequal to eye, its
127 length 7.6 to 11.5% SL; very coarse serrations on angle of preopercular margin; pectoral fin long
128 (28–32.5% SL) extending beyond the tip of pelvic fin, barely reaching anus; head length 30–37.3
129 % SL; longest dorsal-fin spine (fifth) (12.1–19.1 % SL); relatively long and much thicker second
130 anal-fin spine (16.4–21.8 % SL), long caudal peduncle (15.2–20% of SL), and a large size of the
131 penultimate (14.7–19.1 % in SL) and last dorsal-fin (7.4–9.5 % in SL) spines which translate to a
132 less deeply notched dorsal fin, eye diameter 0.5 to 0.6 times length of anal fin spine; maxilla
133 reaching anterior border of pupil; seven scale rows between dorsal fin and lateral line; 48 to 50
134 lateral– line scales.

135

136 **Description.** Measurements are presented as percentage of SL in Table 1. Body elongate, with
137 greatest depth at vertical through origin of pelvic fins (2.7 to 3.1 times in SL); predorsal profile is
138 slightly convex with a tenuous depression above the eye; head length 2.7 to 3.3 in SL; eye
139 diameter 9.6–10.6 times in SL and 3.1–3.7 times in head length (HL); interorbital distance 2.1–
140 4.2 in HL; snout slightly convex, length 3.3–4.1 in HL; mouth terminal and moderately oblique;
141 maxilla reaches to or slightly beyond anterior margin of pupil, 3 to 3.8 in HL: maxilla covered by
142 suborbital when mouth is closed; upper and lower jaws with small conical teeth; conspicuously
143 serrated preopercle (Figure 4A); mouth strongly protrusible; one to two rear chin pores, well-
144 separated (Figure 4B); total number of first arch gill-rakers 16, upper limb 5; lower limb 11;
145 anterior narine 12 to 18 in HL: posterior narine 18.8 to 33 in HL; pectoral-fin length 1.6 to 2.2 in
146 HL; predorsal-fin length 2.8 to 3.3 in SL; prepectoral-fin length 2.6 to 3.2 in SL; prepelvic-fin
147 length 2.5 to 2.8 in SL; preanal-fin length 1.4 to 1.5 in SL; fifth dorsal-fin spine 3.3 to 6.5 in HL;
148 second anal-fin spine 4.6 to 6.1 in SL; depth of caudal peduncle 8.8–10.8 times in SL; length of
149 caudal peduncle 5–6.6 in SL; length of penultimate dorsal spine 5.3–6.8 times in SL and last
150 dorsal spine 10.5–13.5 times in SL; lateral-line scales 48–50; scale rows between lateral line and
151 dorsal fin 7; no scales present on anal or dorsal fin membranes (Figure 4c); pelvic fin with
152 elongate filament on first ray (Figure 4D).

153

154 **Color in life.** Body opalescent silver with golden specks; some of the spines reflect iridescent
155 blue in direct light. Opaque to translucent dorsal, anal, fins and dusky caudal fin (Figure 3). Two
156 small dark spots present on the trailing edge of the lower lobe of the caudal fin. A black marking
157 across the marginal edge of the spine dorsal fin membrane (Figure 4C). Brown to blackish spots
158 over the attachment of some scales, especially towards the back of the trunk (Figure 4C). Figure

159 5 is an underwater photograph taken at 218 meters depth in western Puerto Rico where two
160 specimens of the new species, including their live coloration, can be seen.

161

162 **Distribution.** *Rhonciscus pauco* is found on the deep shelf and upper slope of the western coast
163 of the northeastern Caribbean island of Puerto Rico. We are uncertain of the species' exact
164 range, but fishers report capturing them exclusively in fine sediment habitats distributed between
165 the municipalities of Rincón and Mayagüez, off western Puerto Rico (Figure 1). No additional
166 information is currently available.

167

168 **Habitat.** Collection depths range from 200–360 m in fine unconsolidated sediment or mud
169 habitats (Figure 5).

170

171 **Etymology.** The name *pauco* comes from the fisher's nickname Paúco, Edwin Font, who already
172 knew of this fish locally called *burro* or *ronco* (grunt). Mr. Font was the first to report and
173 provided specimens to MS, although it is recognized by various fishers as a component of the
174 deep-water catch in western Puerto Rico.

175

176 **Comparisons.** *Rhonciscus pauco* is morphologically very close to its sister EP species *R.*
177 *branickii* with which many measurements and counts overlaps. However, it can be distinguished
178 from the three species of the genus, the WA *R. crocro*, and both EP species, *R. bayanus* and *R.*
179 *branickii*, by the seven scale rows between the dorsal fin and the lateral line; *R. branickii* has five
180 according to (McKay & Schneider, 1995) or six (our data), while *R. bayanus* and *R. crocro* have
181 eight scale rows above the lateral line. It differs clearly from its WA congener by having 48–50
182 lateral–line scales (vs 66–72 in *R. crocro*) and 11 short lower gill rakers (vs 7–9 in *R. crocro*).
183 Our scale counts for *R. crocro* differ from those presented by Lindeman & Toxey (2002), who
184 report five and six rows between the dorsal fin and the lateral line and 53–55 lateral–line scales
185 as opposed to eight rows and 66–72 lateral–line scales. In both cases the new species can be
186 unambiguously distinguished. The new species has a coarse serrated preopercle, with 2–3 large
187 spines at the corner and 20–21 relatively small spines on the vertical border; the preopercle is
188 weakly or not serrated in *R. bayanus*. *Rhonciscus pauco* has much larger eyes (9.4–10.4% of SL)
189 compared to 7.2–8.1% in *R. bayanus*, 7.1–8.9% in *R. branickii*, and 6.7–7.8% in *R. crocro*.
190 Bussing (1993) reported that the eye diameter of *R. branickii* ranged between 2.9 and 3.8 times
191 in head length while McKay & Schneider (1995) published 3.1–3.4; Meek & Hildebrand (1925)
192 reported larger eyes (2.6 to 3.2) based on specimens smaller than 15 cm. Our data for *R. pauco*
193 (Table 2: 3.08–3.66) overlap such information; however, the lack of size data in Bussing (1993)
194 and McKay & Schneider (1995) precludes a more detailed comparison. With our data, that are
195 size comparable, *R. pauco* can be clearly separated from *R. branickii*.
196 Furthermore, *R. pauco* has a longer caudal peduncle (15.2–20 % of SL) compared to 11.9–16.3
197 % in *R. bayanus*, 14.0–15.5 % in *R. branickii* and 11.1–14.9 % in *R. crocro*. The larger size of
198 the penultimate (14.7–19.1 % in SL) and last dorsal-fin (7.4–9.5 % in SL) spines translate to a

199 less deeply notched dorsal fin in *R. pauco*. Additionally, similarly sized *R. pauco* can be
200 distinguished from its EP sister species *R. branickii* by having longer snouts and longer maxilla
201 (3.24–4.09 and 3–3.77 in HL in *R. pauco* vs 4.41–5.27 and 3.86–4.69 in *R. branickii*). A detailed
202 comparison of morphometric proportions is included in Table 2. Life coloration is another
203 feature separating the new Puerto Rican species from *R. branickii*; *R. pauco* is light silver to
204 golden in color, with opalescence, while its sister species EP is dull dark brown, without bright
205 colors or opalescence, and with a darker marking along the entire opercular margin.
206

207 Discussion

208 The unexpected discovery of a new species of grunt at this depth on the Puerto Rican slope is an
209 issue of biogeographic interest in the Caribbean. For snapper and grouper fishermen in deep
210 waters off the west coast of Puerto Rico, this species is well known, despite having gone
211 unnoticed and not being formally described until now. *R. pauco* is captured incidentally with the
212 snappers *Etelis oculatus* and *Pristipomoides macrophthalmus* but discarded due to its low market
213 value. It is commonly referred to as *burro*, *ronco* or *viejo*, the latter name also used by some
214 fishers to identify the congener grunt, *R. crocro*, that is not rare in shallow, brackish waters of
215 large volume rivers throughout Puerto Rico (Engman et al., 2019).

216 Other than a new record of a single specimen of *R. branickii* (USNM 422650) collected in the
217 eastern Pacific off Panama at 430 to 500m, only six Caribbean grunt species occur at one
218 hundred meters depth or below, with 120 m as the maximum known depth (Robertson et al.,
219 2019). The new species is found inhabiting waters deeper than 200 m where there is extremely
220 low light penetration.

221 What is even more surprising is that two of the four *Rhonciscus* species are known to occupy
222 very shallow, often brackish or freshwater environments. The type species of the genus, *R.*
223 *crocro*, inhabits waters shallower than 20 m and is frequently found in the lower parts of short,
224 rapid rivers or slow creeks in eastern Florida (Lindeman pers. com. 2022) as well as in 1 m or
225 less in depth in the Rio Grande de Añasco river, where it flows into the ocean (MS pers. obs.).
226 The two EP *Rhonciscus* species are also reported in shallow water, especially *R. bayanus*, known
227 at depths less than 10 m (Robertson & Allen, 2015). *Rhonciscus branickii*, on the other hand, has
228 been reported once at a depth of 500 m; this species is very similar to *R. pauco* and is considered
229 its sister species. However, *R. branickii* is an EP species. Besides this deep record no other grunt
230 of this genus been reported from depths at which *R. pauco* has been caught. The evolutionary
231 processes that led to the existence of this deep-water grunt in the northeastern Caribbean, far
232 away from the continental shores of Central and South America with its WA congener known
233 primarily from coastal rivers, are of utmost biogeographical interest.

234 Finally, the phylogenetic tree (Figure 6), which includes all valid species of the genus, resulted in
235 a topology with *R. pauco* placed as a sister species to the EP *R. branickii*, with a sequence
236 divergence of 1.7–2.3%, establishing a new trans-isthmian sister-pair within the family
237 Haemulidae. Remaining COI genetic distances of *R. pauco* are 13.6–14% with *R. bayanus* and
238 12.7–13.2% with *R. crocro*. The distance between these geminate species across the isthmus of

239 Panama is relatively small (1.7–2.3%) yet consistent with values of two other trans-isthmian
240 pairs in the genus *Anisotremus* (2.0–2.4%) (Tavera *et al.*, 2012). The COI genetic distances in
241 seven trans-isthmian sister pairs of Haemulidae range from 2.0% between *Anisotremus*
242 *surinamensis* (WA) and *A. interruptus* (EP) to 18% between *Genyatremus cavifrons* (WA) and
243 *G. pacifici* (EP). Interspecific distance values near 2% divergence have been reported in both
244 freshwater and marine fishes (Ward *et al.*, 2005; Shen *et al.*, 2016). In any case, interspecific
245 genetic distances between *R. paucio* and *R. branickii* are larger than the intraspecific genetic
246 distances (*R. paucio*: 0% and *R. branickii*: 0.2–0.8%).

247 It is common to find variable intra- and interspecific distances and defining a threshold becomes
248 difficult as the mutation rate varies considerably among species. A small distance may indicate
249 very strong differentiation between sister species that have diverged comparatively recently,
250 while COI will not detect “substantial” differentiation. Perhaps this marker in this group evolves
251 quite slowly despite the irrefutable fact that the new species is reproductively isolated, adapted to
252 different environmental conditions, yet resembling its EP sibling species. The magnitude of
253 variability in the mtDNA divergence between all pairs of trans-isthmian grunts is consistent with
254 an asynchronous divergence, as described for other taxa (Knowlton & Weigt, 1998; Leigh,
255 O’Dea & Vermeij, 2014; O’Dea *et al.*, 2016).

276

277 **Conclusions**

278 Based on morphology, geographic distribution, and molecular analyses, this study describes as a
279 new species the first known western Atlantic deep-sea-dwelling grunt collected from the upper
280 Puerto Rican slope. This finding is an issue of evolutionary and biogeographic interest for the
281 family, which is composed of shallow water species, commonly found on upper shelf waters up
282 to 100 m in depth with a strong preference for shallow environments of less than 40 m.
283 Moreover, the fact that some species of the genus *Rhonciscus* are frequently found in estuaries,
284 rivers and freshwater streams makes this finding more remarkable.

285
286

287 **Acknowledgements**

288 We are indebted with E. Font for the initial collection of specimens and for sharing the
289 traditional ecological knowledge of this fish and its habits, as well as H. Vargas that provided
290 additional specimens that led to the scientific recognition of this new species of grunt. The
291 authors are extremely appreciative of A. Veglia and N. Schizas of the Department of Marine
292 Sciences of the University of Puerto Rico for initial advice. K. Overly and T. Battista were
293 instrumental in obtaining the photo from a NOAA NCCOS 2022 ROV dive off western Puerto
294 Rico. Puerto Rico Department of Natural and Environmental Resources collection permit #
295 2017-IC-031. Contribution No. 19 of the Instituto de Ciencias del Mar y Limnología de la
296 Universidad del Valle, INCIMAR. Contribution No. xxxx of the Instituto de Estudio de las
297 Ciencias del Mar, CECIMAR.
