Structure and Criteria

Structure your review

The review form is divided into 5 sections. Please consider these when composing your review:

1. BASIC REPORTING
2. EXPERIMENTAL DESIGN
3. VALIDITY OF THE FINDINGS
4. General comments
5. Confidential notes to the editor

 You can also annotate this PDF and upload it as part of your review

When ready [submit online](#).

Editorial Criteria

Use these criteria points to structure your review. The full detailed editorial criteria is on your [guidance page](#).

BASIC REPORTING

-  Clear, unambiguous, professional English language used throughout.
-  Intro & background to show context. Literature well referenced & relevant.
-  Structure conforms to [Peerj standards](#), discipline norm, or improved for clarity.
-  Figures are relevant, high quality, well labelled & described.
-  Raw data supplied (see [Peerj policy](#)).

EXPERIMENTAL DESIGN

-  Original primary research within [Scope of the journal](#).
-  Research question well defined, relevant & meaningful. It is stated how the research fills an identified knowledge gap.
-  Rigorous investigation performed to a high technical & ethical standard.
-  Methods described with sufficient detail & information to replicate.

VALIDITY OF THE FINDINGS

-  Impact and novelty not assessed. *Meaningful* replication encouraged where rationale & benefit to literature is clearly stated.
-  All underlying data have been provided; they are robust, statistically sound, & controlled.
-  Conclusions are well stated, linked to original research question & limited to supporting results.

The best reviewers use these techniques

Tip

Example

Support criticisms with evidence from the text or from other sources

Smith et al (J of Methodology, 2005, V3, pp 123) have shown that the analysis you use in Lines 241-250 is not the most appropriate for this situation. Please explain why you used this method.

Give specific suggestions on how to improve the manuscript

Your introduction needs more detail. I suggest that you improve the description at lines 57- 86 to provide more justification for your study (specifically, you should expand upon the knowledge gap being filled).

Comment on language and grammar issues

The English language should be improved to ensure that an international audience can clearly understand your text. Some examples where the language could be improved include lines 23, 77, 121, 128 - the current phrasing makes comprehension difficult. I suggest you have a colleague who is proficient in English and familiar with the subject matter review your manuscript, or contact a professional editing service.

Organize by importance of the issues, and number your points

- 1. Your most important issue*
- 2. The next most important item*
- 3. ...*
- 4. The least important points*

Please provide constructive criticism, and avoid personal opinions

I thank you for providing the raw data, however your supplemental files need more descriptive metadata identifiers to be useful to future readers. Although your results are compelling, the data analysis should be improved in the following ways: AA, BB, CC

Comment on strengths (as well as weaknesses) of the manuscript

I commend the authors for their extensive data set, compiled over many years of detailed fieldwork. In addition, the manuscript is clearly written in professional, unambiguous language. If there is a weakness, it is in the statistical analysis (as I have noted above) which should be improved upon before Acceptance.

Microplastic pollution at Qilianyu, the largest green turtle nesting grounds in the northern South China Sea

As new persistent pollutants, microplastics have recently attracted considerable attention. When they are present in beach sediments, microplastics may adversely affect the nesting and hatching of sea turtles, which rely on beaches to reproduce. In this study, microplastic pollution at Qilianyu was investigated. Qilianyu is located in the northeastern Xisha Islands and has the largest known nesting grounds for green turtles in China. The present results indicate that the average abundance of microplastics in the beach surface sediments was 338.44 ± 315.69 thousand pieces·m⁻³ or 1353.78 ± 853.68 pieces·m⁻², with foam and plastic blocks being the main microplastics identified. The microplastic particles were categorized as small and were predominantly within the 0.05–1 mm size category. Most microplastic particles were white. Polystyrene and polyethylene were found to be the most common forms of plastic present. Microplastic pollution was observed not only on the surface of the nesting grounds but also at the bottom of the nests at approximately 60 cm depth, which may be harmful to the incubation of sea turtle eggs. Based on the present findings, removing plastic litter on beaches is suggested to reduce the threat of microplastic pollution to marine life, including sea turtles. This is particularly the case for small pieces of plastic. Furthermore, the foam used in aquaculture should be recovered and replaced before it becomes fragmented owing to age. In addition, regional cooperation between stakeholders in the South China Sea should be strengthened to collectively promote the reduction and cleanup of marine litter.

32 1. Introduction

33 Marine plastic pollution is a common worldwide environmental problem (Martin et al.,
34 2019). Plastic fragments in the ocean are easily broken down into many miniature fragments or
35 particles as a result of long-term physical and chemical action (Andrady, 2011; Hopewell et al.,
36 2009). Microplastics are defined as plastic fragments or particles that have a diameter of less
37 than ~~5mm~~ (Arthur et al., 2009). It is estimated that approximately 51 trillion plastic particles are
38 present in the world's oceans (Tirkey et al., 2021; Wessel et al., 2016). Microplastics in the
39 environment can migrate over long distances through external forces such as wind, rivers, and
40 ocean currents. They can pollute some of the most remote corners of the earth, from mountain
41 lakes to deep-sea sediments (Gago et al., 2018; Moreira et al., 2016; Nelms et al., 2017).
42 Microplastics are a new pollutant in the current marine environment and are gaining increasing
43 global attention (Andrady, 2011). However, most studies focus on offshore waters, with ~~research~~
44 ~~focused~~ on remote areas such as deep seas, polar regions, islands and reefs ~~still being extremely~~
45 ~~limited~~ (Auta et al., 2017; Imhof et al., 2017).

46 Sea turtles are highly loyal to their nesting grounds, with most adult ~~female sea turtles~~
47 returning to the beach where they were born to lay their eggs (Triessnig et al., 2012). The
48 presence of microplastics on ~~the beach~~ can have a negative effect on the reproductive cycle of
49 sea turtles (Beckwith et al., 2018; Duncan et al., 2018). Sea turtles have temperature-dependent
50 sex determination, meaning that the sex ~~determination for this species~~ depends on the incubation
51 temperature. ~~This is determined by the nest temperature during the~~ mid-stage of the incubation
52 period (Mrosovsky & Yntema, 1980). The specific heat capacity of plastics is higher than that of

53 sand. Microplastics that have become incorporated into the beach sand will increase the overall
54 temperature of the beach. This will then affect the nest temperature, which will cause a gender
55 imbalance in sea turtles (Andrady, 2011; Beckwith & Fuentes, 2018). Furthermore, microplastics
56 can absorb harmful chemical pollutants. This can affect the embryonic development of sea turtles
57 through osmosis, which can decrease hatching success (Bergeron, 1994; Yang et al., 2011).
58 Duncan et al. (2018) first discovered microplastics at a depth of 60 cm (nest depth) in nesting
59 areas for sea turtles in Mediterranean Cyprus, which considered that the presence of
60 microplastics may affect the hatching success rate and sex ratio of sea turtles, threatening their
61 population sustainability.

62 The populations of sea turtles in China have dropped sharply owing to massive illegal trade
63 and habitat loss, resulting in the loss of almost all nesting beaches (Lin et al., 2021). The Xisha
64 Islands in the South China Sea are currently the largest nesting grounds for green turtles in China.
65 A total of 100 green turtle nests were recorded per year from 2016 to 2019 (Jia et al., 2019;
66 Wang et al., 2019). These islands are the last surviving relatively intact land area in China where
67 sea turtle reproduction still occurs. This is due to the remoteness of the islands from the mainland
68 and low human population owing to low levels of development. The green turtle population in
69 the Xisha Islands has a unique genetic makeup, representing a newly defined population
70 (Gaillard et al., 2019). It is therefore vital to protect this distinct turtle population and their
71 nesting grounds to ensure the survival of these turtles into the future.

72 In this study, the abundance of microplastics in the nesting grounds of green turtles at
73 Qilianyu, Northeastern Xisha Islands is evaluated. The characteristics and possible sources of

74 microplastic pollutants are also described. ~~Revised management practices are also proposed,~~ in
75 line with survey results. These data will help fill gaps in knowledge about microplastic pollution
76 in ~~green turtle~~ habitats in ~~China~~. ~~Furthermore, it~~ will provide basic information and references
77 for the protection, management, and ecological restoration of beaches as sea turtle nesting
78 grounds in the South China Sea.

79 **2. Materials and methods**

80 **2.1 Study area**

81 ~~The Qilianyu cluster (16°55'N 17°00' N, 112°12'E 112°21' E)~~ is located in the
82 northeastern Xisha Islands in the South China Sea, approximately 330 km from Hainan Island.
83 The eight small islands are connected by reefs, with a total area of approximately 1.32 km². The
84 current permanent population is approximately 200, primarily living on Zhaoshu Island. ~~With the~~
85 ~~exception of Zhaoshu Island and North Island, all other islands in the archipelago are~~
86 ~~uninhabited~~. In this study, sampling points were set up on six islands, including North Island
87 (NI), Middle Island (MI), South Island (SI), North Sand (NS), Middle Sand (MS), and South
88 Sand (SS). These islands have ~~very good quality nesting sites for green turtles~~ and have records
89 of ~~green turtles laying eggs there in recent years~~ (Figure 1).

90 **2.2 Sample collection and separation**

91 The geographic coordinates of the sample points were recorded using a global positioning
92 system. Sediment samples within an area of 25 cm × 25 cm and a depth of 0–2 cm ~~were collected~~
93 from both the strand line and the turtle nesting line (TNL) for six nesting grounds. This sampling
94 process was repeated three times at each nesting ground. Additional samples were collected from

95 the TNL using a custom-made cylindrical galvanised steel core with a diameter of 20 cm.
96 Samples were collected at depths of 0–60 cm (0–2 cm, <2–20 cm, <20–40 cm, and <40–60 cm).
97 ~~This was to further~~ explore the presence and extent of microplastic pollution at the depth where
98 sea turtles nest at approximately 60 cm (Duncan et al., 2018).

99 The saturated sodium chloride density method described by Zhang et al. (2021) was used to
100 separate the microplastics from the sediment. For each sample, 250 cm³ was weighed and placed
101 in a beaker. A total of 500 mL of saturated sodium chloride solution was added. The mixture was
102 then stirred for 2 minutes, after which it was left to settle for 10 minutes. The supernatant was
103 then passed through a ~~300-mesh~~ sieve. The remaining ~~compositions from the~~ beaker were added
104 to sodium iodide solution and stirred for 2 minutes, after which the mixture was left to settle for
105 10 minutes. After density separation had taken place, the sample was transferred to a 100 mL
106 beaker. A solution of 10% potassium hydroxide was added, and the mixture was left to digest for
107 two days. Finally, the supernatant solution was decanted and filtered through a 0.45 µm glass
108 fiber membrane (GF/F, 47 mm Ø, Whatman, Shanghai, China). This was done using a vacuum
109 filtration device (GM-0.33A, Zhengzhou, China), while waiting for the one-step analysis.

110 **2.3 Observation and identification of microplastics**

111 All samples on the filter membrane were observed under a stereo microscope (SMZ-168
112 SERIES, MOTIC, Xiamen, China), and images were obtained with a SONY DSC-RX10M2
113 digital camera. The microplastics were classified and counted according to their morphological
114 characteristics, color, and size (Zhang et al., 2021).

115 Samples suspected to be microplastics that were representative of each group were
116 randomly selected, and their surface structures were tested for polymer types using a Fourier

117 transform infrared spectrophotometer (IRTracer-100, SHIMADZU, Japan). The detector spectral
118 range was 600–4,000 cm^{-1} , co-adding 16 scans at a resolution of 8 cm^{-1} (Zhang et al., 2021). The
119 resulting atlas was compared to the IR polymer spectral library, with only readings at a
120 confidence level of 70% or higher being considered reliable and accepted.

121 **2.4 Experiment quality control**

122 All containers were rinsed at least three times with Milli-Q water and then dried before the
123 start of the experiments. All plastic equipment was replaced with non-plastic if possible. If this
124 was not possible, they were rinsed three times with Milli-Q water and then inspected to ensure
125 that no plastic fragments were generated during sample processing. In addition, all containers
126 were always covered with aluminum foil to avoid contamination. Nitrile gloves and cotton lab
127 coats were ~~constantly~~ worn throughout the experiment, with lab windows ~~also~~ remaining closed.
128 Three procedural blanks were set to minimize contamination from the environment.

129 **2.5 Statistical analysis**

130 Statistical analysis was performed using Excel and SPSS 19.0 statistical software. All data
131 were tested for normal distribution and variance homogeneity before the statistical analysis. One-
132 way analysis of variance was used to analyze the difference in microplastic abundance between
133 the six nesting grounds. The relevant data are shown as mean \pm standard deviation. $P < 0.05$ was
134 considered a significant difference, and $P < 0.01$ was considered a highly significant difference
135 according to the two-tailed test.

136 **3. Results**

137 **3.1 Distribution and abundance of microplastics pollution at Qilianyu**

138 The quantity of microplastics found in the nesting grounds at Qilianyu ranged from 92—
139 782 thousand pieces·m⁻³ or 368—3128 pieces·m⁻², with an average abundance of 338.44 ±
140 315.69 thousand pieces·m⁻³ or 1353.78 ± 853.68 pieces·m⁻². The distribution of microplastics
141 across the six islands had a degree of spatial variation (Figure 2). MS was the nesting ground that
142 was most severely polluted with microplastics, followed by NS, SI, and NI, respectively (*df* = 17;
143 *F* = 7.202; *P* = 0.002). In contrast, MI and SS were ~~found to be~~ less polluted in comparison to the
144 other sampling sites. The abundance of microplastics in the sediment samples exhibited a gradual
145 increase from northwest to southeast, with the exception of MI and SS.

146  Although many ~~investigations and studies into~~ beach microplastic pollution exist, the
147 particle size survey range is not ~~uniform. This makes~~ it difficult to compare the variation in
148 abundance of microplastics at the regional level. Therefore, only broad comparisons ~~were~~ made
149 for the same particle sizes across different studies. When comparing the abundance of beach
150 microplastics with other areas (Table S1), ~~results showed that~~ the abundance of microplastics
151 (0.05–5 mm in size) in nesting grounds of ~~green turtles~~ at Qilianyu was lower than in Hainan
152 Island, Hong Kong, and Guangdong Province,  but similar to Ganquan and Quanfu Island in the
153 Xisha Islands. Moreover, microplastics with a particle size range of 0.05–0.33 mm accounted for
154 27.79 % of all particles in this study. The actual abundance of microplastics at Qilianyu is
155 therefore considerably lower than that found in Guangdong and  Hong Kong. It is likely that the
156 lower abundance of microplastics at Qilianyu in the Xisha Islands is associated with increasing
157 distance from the mainland.

158 3.2 Morphological characteristics of microplastics

159 When ~~they were separated, the~~ microplastics were shown to have different morphological
160 characteristics. Figure S1 shows the shape category of the microplastics found in the samples.
161 Among the microparticles observed, plastic blocks formed the largest proportion at 58.74 %,
162 followed by foams at 36.01 % and fibers at 4.76 %. Meanwhile, microbeads and films were
163 ~~found to be~~ relatively rare, accounting for only 0.75 % of the total microplastic particles (Figure
164 3).

165 The most common color of the sampled microplastics was white. ~~This included both~~
166 ~~transparent and white microplastics (68.71 %).~~ Among these, white foam was the most common
167 type. The second most common color was black (23.87 %), Multicolored microplastics such as
168 yellow, green, gray, and blue were relatively rare, ~~as shown in Figure 4.~~ The average size of the
169 microplastics at Qilianyu is indicated in Figure 5. Small microplastic particles (<1 mm)
170 comprised the majority of the microplastics (90.22 %).

171 3.3 Polymer compositions of microplastics

172 The polymer compositions of the microplastics included polyethylene (PE), polypropylene
173 (PP), and polystyrene (PS) (Figure S2). The most common polymer compositions were PS
174 (40.74 %) and PE (40.74 %). ~~Foams comprised PS, fibers and microbeads comprised PE, and~~
175 ~~plastic blocks primarily included PE or PP~~ (Figure 6).

176 3.4 Changes in microplastic density with increasing sampling depth

177 ~~Results showed that as~~ the sampling depth increased, the average density of the
178 microplastics decreased. When the depths were 0–2, <2–20, <20–40, and <40–60 cm, the

179 average microplastic densities were 418.89 ± 270.41 , 415.11 ± 301.35 , 277.85 ± 140.14 and
180 264.67 ± 200.40 thousand pieces·m⁻³. However, there was no significant difference between
181 microplastic densities at each depth ($df = 66$; $F = 2.043$; $P = 0.117 > 0.05$) (Figure 7). This
182 ~~indicated~~ that microplastic pollution was not limited to the ~~surface of green turtle nests but can~~
183 ~~also be found deeper underground. This means~~ that microplastics can come into close contact
184 with the turtle eggs, which usually lie at a depth of 60 cm.

185 4. Discussion

186 4.1 Current status of microplastic pollution at Qilianyu

187 Beaches are gathering points for ocean microplastics and key areas of environmental
188 pollution (Nelms et al., 2016; Poeta et al., 2014). Although ~~the island is~~ relatively remote from
189 the mainland, the nesting grounds ~~of the green turtles at Qilianyu have still been exposed to~~
190 microplastic pollution. Microplastic pollution is closely related to regional population activities
191 and economic development (Fang et al., 2021). The overall abundance of microplastics (size
192 range 0.05–5 mm) at Qilianyu was lower than that at other places such as Hainan and
193 Guangdong, China. This is likely ~~the small population~~ of the islands, implying that it is less
194 severely affected by land-sourced plastic litter. However, microplastics are stable and can exist
195 in the environment for a long time. Therefore, their abundance may increase with time. Measures
196 need to be taken to prevent the microplastic pollution increase in Qilianyu.

197 4.2 Sources of microplastic pollution for Qilianyu

198 The types of microplastics found at the nesting grounds at Qilianyu were primarily plastic
199 blocks and foams, with the main compositions being PS and PE. ~~However~~, Huang et al. (2020)

200 showed that the types of microplastics found in the sea water of the Xisha Islands are primarily
201 fibers and films, with the composition predominantly being ~~polyethylene~~ terephthalate (56.2%)
202 and PP (20.3%). The different types and compositions found indicate that microplastics in beach
203 sediment at Qilianyu ~~may not be directly derived~~ from local sea water but instead  come primarily
204 from beach debris.

205 ~~Previous investigations have found that the greatest proportion of beach debris at Qilianyu~~
206 ~~is plastic and foam (Zhang et al., 2020)~~ (Figure S3). Plastic blocks and foam can easily break in a
207 beach ~~environment. This is more common under higher temperatures as a result of weathering~~
208 ~~and degradation~~ (Fok & Cheung, 2015; Fok et al., 2017). Owing to its tropical climate, Qilianyu
209 experiences strong direct solar radiation, accounting for 60–70% of the world’s solar radiation.
210 The average annual average temperature is approximately 27.4 °C (Xu et al., 2018), which is
211 conducive to the breakdown of plastic. Furthermore, the highest percentage of the microplastics
212 at Qilianyu were white in color, followed by black. In line with the results of 24 investigations
213 analyzed by Hidalgo-Ruz et al. (2012), this is likely to be because of the weathering and fading
214 of plastics in beach or ocean environments. Therefore, it is likely that most of the microplastics
215 found ~~as part the current study~~ were from broken plastic debris on the beach. Items such as
216 plastic bottle caps being broken into small plastic particles on the beach were commonly seen
217 during field work (Figure S4).

218 Furthermore, Zhang et al. (2020) confirmed that the geographic source of beach litter at
219 Qilianyu was primarily from ~~abroad, primarily from~~ Southeast Asian countries, such as Vietnam
220 and Malaysia. Therefore, it is likely that the microplastics in the nesting grounds for the green

221 turtles at Qilianyu were produced from plastic litter from abroad that drifted there with the ocean
222 currents, washed ashore, and then was broken into smaller fragments on the beach.

223 **4.3 Potential threats of microplastic pollution to sea turtles at Qilianyu**

224 Consistent with previous research results (Mohamed Nor & Obbard, 2014; Peng et al., 2017;
225 Vianello et al., 2013), the microplastics found in the nesting grounds on Qilianyu were
226 predominantly small particles (0.05–1 mm). However, the smaller the microplastic particle size,
227 the larger their specific surface area. ~~Implying that they~~ can absorb more pollutants, which may
228 cause greater harm in the hatching of green turtles (Duncan et al., 2018).

229 The presence of microplastics is extensive in the sea turtle nesting grounds at Qilianyu, with
230 them even coming into close contact with their eggs. Owing to the effects of climate change and
231 the presence of microplastics, the beach temperature at Qilianyu has ~~been increasing~~ annually.
232 Temperatures have increased by 1 to 2 °C in 2021 in comparison with data collected in 2018 (T.
233 Zhang and L. Lin, unpublished data.). An increased incubation temperature may change the sex
234 ratio of ~~any~~ sea turtles ~~which~~ are born locally. **In addition, the microplastic surfaces can**
235 **accumulate heavy metals and organic pollutants (Bergeron, 1994; Yang et al., 2011).** Jian et al.
236 (2020) indicated that heavy metals can enter the embryo through penetration of the shell
237 membrane. Therefore, we ~~opined~~ that microplastics near ~~the green turtle~~ nests may adversely
238 affect the development of turtle embryos. However, the degree of harm to the hatching of ~~green~~
239 ~~turtle~~ eggs due to microplastics at Qilianyu is not yet clear. Therefore, research and ~~monitoring~~
240 ~~in this field~~ needs to be strengthened going forward. Important areas for future research include
241 the impact of microplastic enrichment on turtle hatching temperature, and the impact of attached

242 microplastic surface pollutants on sea turtle hatching.

243 **4.4 Management Suggestions**

244 Foketal et al. (2017) ~~opined~~ that cleaning up plastic litter on beaches may reduce the
245 generation of microplastics there. However, the current beach litter cleaning at Qilianyu
246 primarily removes large plastic litter of a size > 10 cm. The overall amount of large litter has
247 been reduced to a low level by regular cleaning efforts. However, a large amount of small litter
248 (1–10 cm) still remains after cleaning has taken place. The proportion of smaller pieces of litter
249 being removed requires improvement (Zhang et al., 2020). In addition, during the peak period for
250 sea turtle nesting, the accumulation rate of plastic litter on the ~~green turtle~~ nesting ground beach
251 at North Island of Qilianyu was $1.01 \text{ pieces} \cdot \text{m}^{-2} \cdot \text{month}^{-1}$. This was higher than that found by
252 other studies (D. Q. Li and L. Lin, unpublished data.). This plastic litter should be cleaned up ~~in~~
253 ~~time~~ to prevent it from breaking down to form microplastics. Therefore, it is suggested that the
254 strength and frequency of beach litter cleaning should increase. ~~This should particularly focus on~~
255 ~~the removal of small plastic particles and foam, with cleaning frequency being increased from~~
256 ~~once a week to once every 2–3 days.~~ In view of the increasing number of foam plastics, it is
257 ~~suggested~~ that the foam used for local commercial activities such as aquaculture and seafood
258 transportation should be recovered and replaced before aging and ~~fragmentation~~ into smaller
259 ~~pieces of plastic litter occurs.~~

260 Considering the litter at Qilianyu ~~being~~ primarily from abroad, regional cooperation
261 between stakeholders in the South China Sea should be strengthened, with joint promotion taking
262 place about the appropriate treatment of marine litter. This will help to reduce the generation of

263 large plastic litter and prevent large plastics from breaking down to form ~~more~~ microplastics, to
264 the benefit of the conservation of ~~the green turtle~~ populations of the South China ~~sea~~.

Figure 1

Figure 1. Map of study area and sampling points.

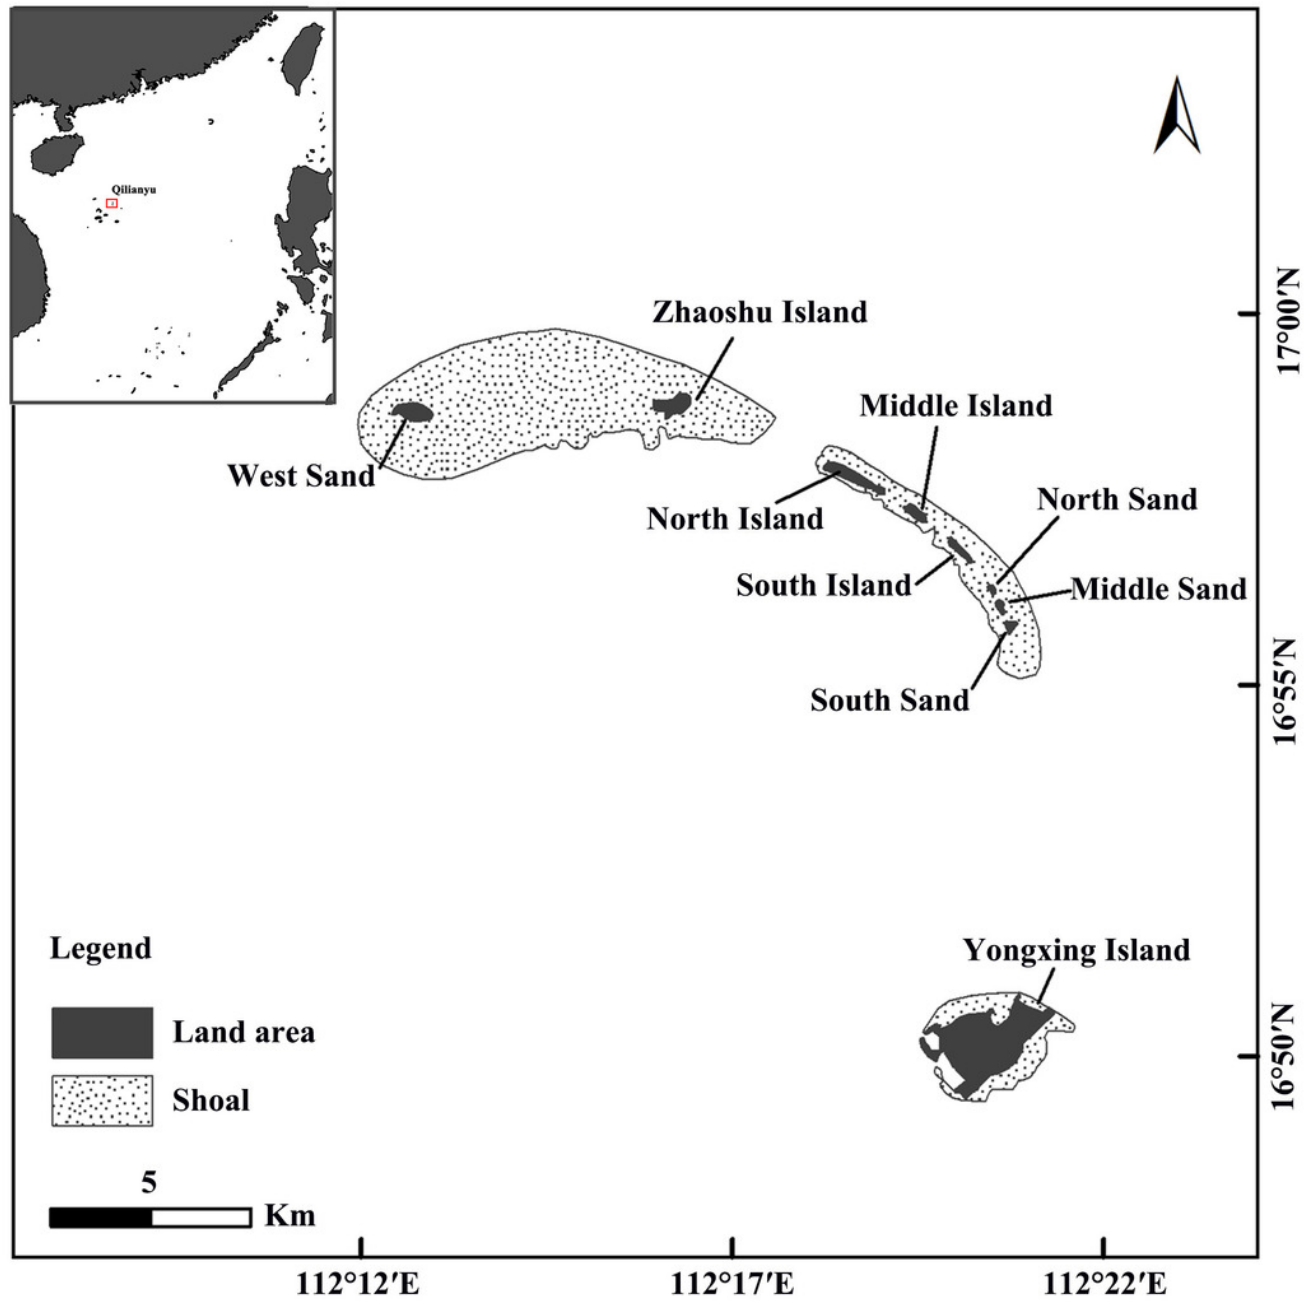

Figure 2

Figure 2. Microplastic abundance in surface sediments of six nesting grounds at Qilianyu. Different lowercase letters in the figure indicate significant differences at the $P < 0.05$ level. 

~~Different lowercase letters in the figure indicate significant differences at the $P < 0.05$ level.~~

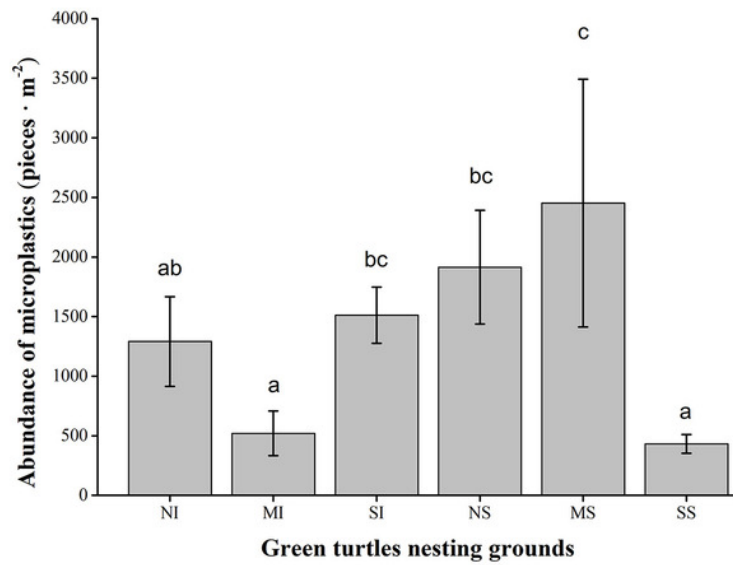

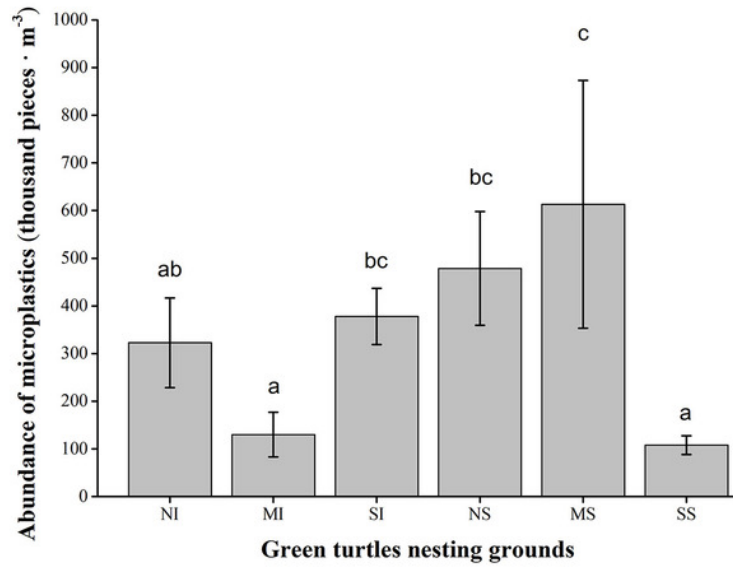

Figure 3

Figure 3. Composition (%) of microplastics with different shapes (n = 18).

The solid horizontal lines from the top to the bottom of each box plot indicate the maximum value, 75% quartile, median, 25% quartile, and minimum value. Empty boxes indicate average values, and solid circles are outliers.

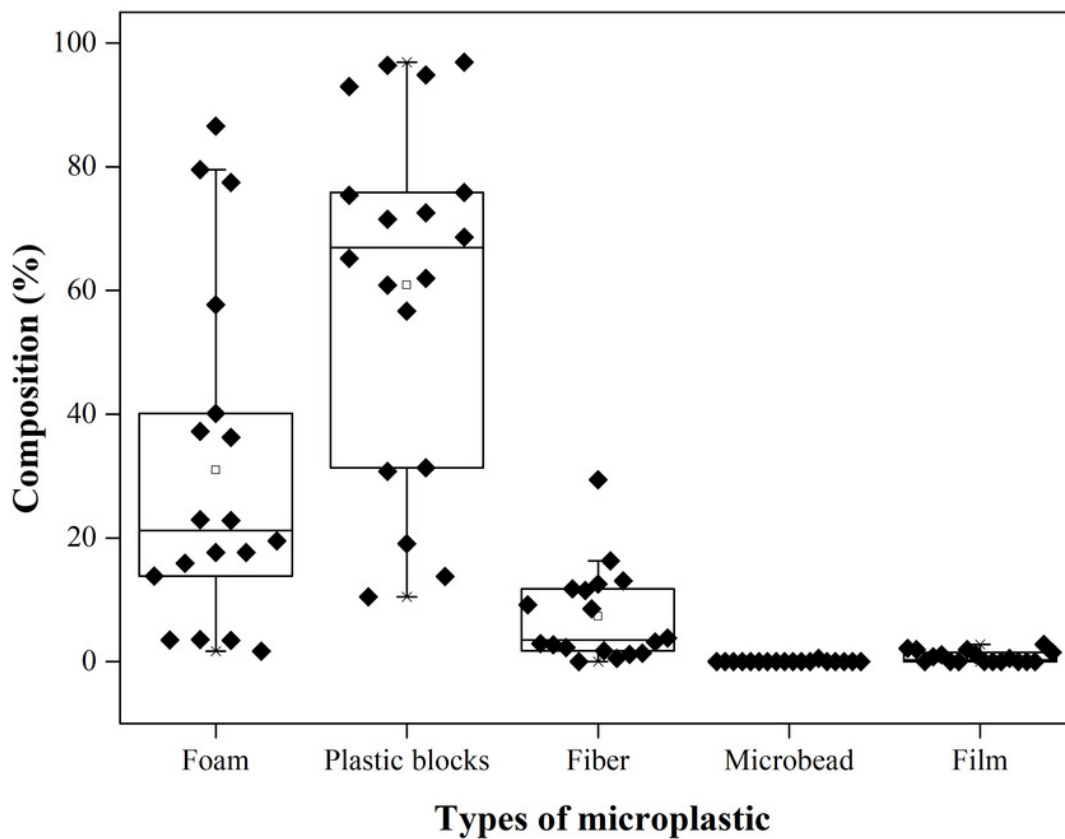

Figure 4

Figure 4. Composition (%) of microplastics with different colors (n = 18).

The solid horizontal lines from the top to the bottom of each box plot indicate the maximum value, 75% quartile, median, 25% quartile, and minimum value. Empty boxes indicate average values, and solid circles are outliers.

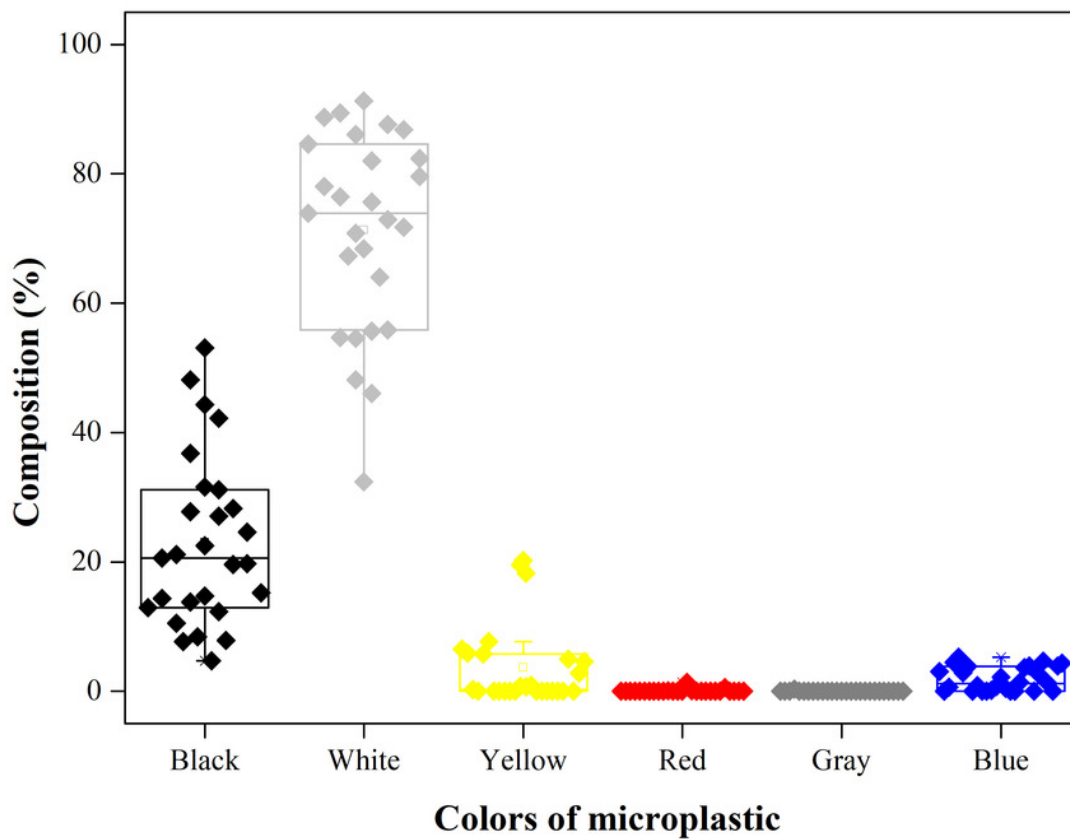

Figure 5

Figure 5. Composition (%) of microplastics with different grain sizes (n = 18).

The solid horizontal lines from the top to the bottom of each box plot indicate the maximum value, 75% quartile, median, 25% quartile, and minimum value. Empty boxes indicate average values, and solid circles are outliers.

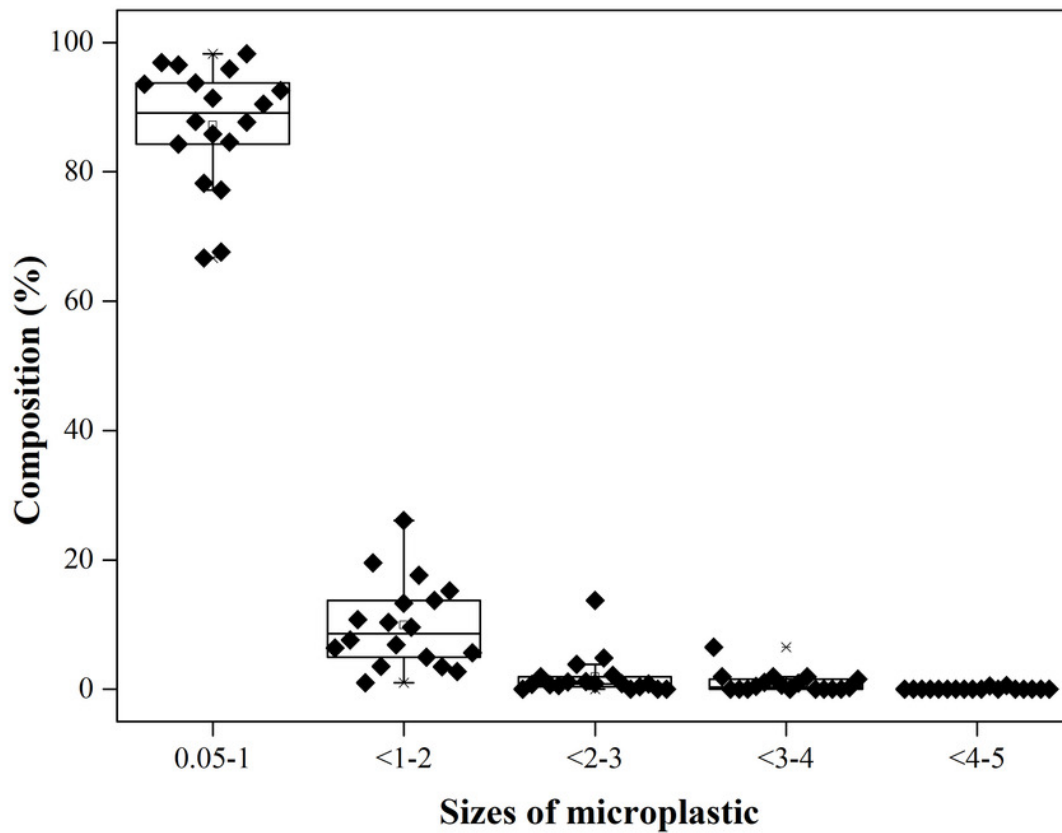

Figure 6

Figure 6. Composition of the selected items from six nesting grounds at Qilianyu.

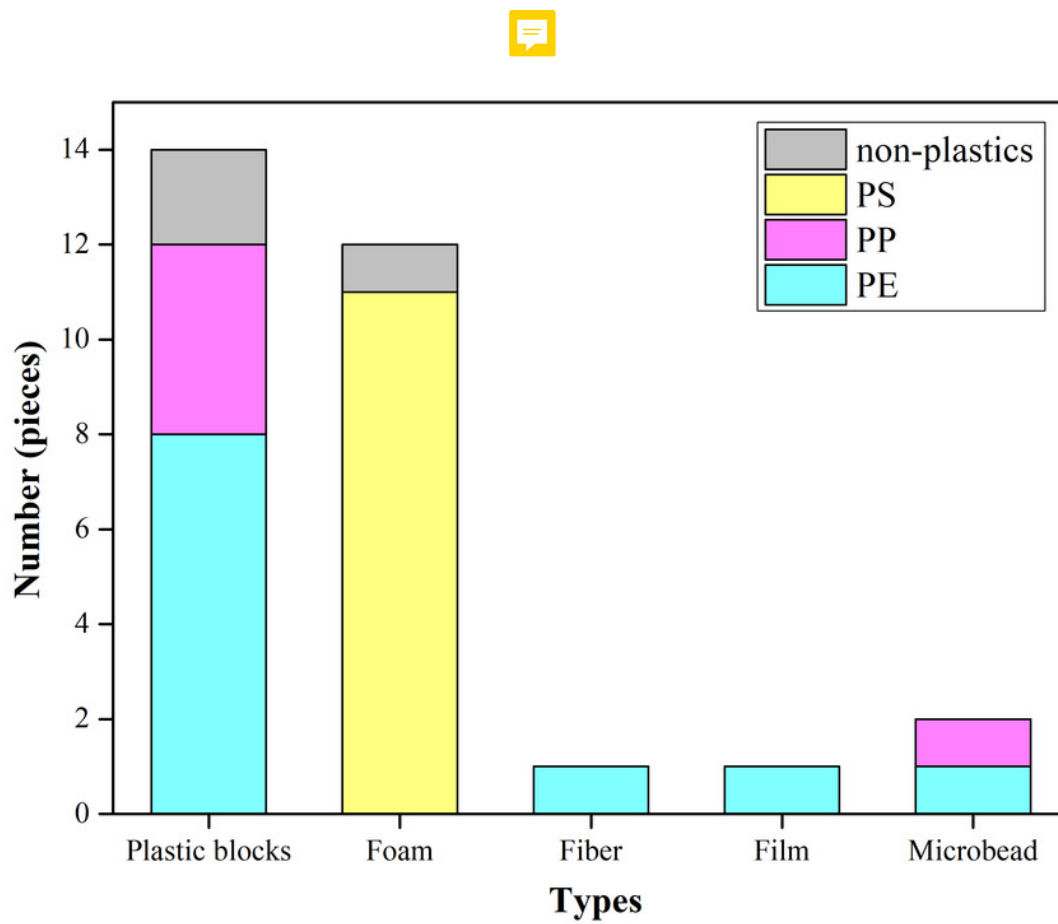

Figure 7

Figure 7. Values of average microplastic abundance at different depths in the nesting grounds of green turtles.
