Background. Thrombocytopenia, an early common complication in heatstroke (HS), has been widely considered as a mortality predictor of HS. The mechanism underlying thrombocytopenia in HS remains unknown. It is not known whether NOD-like receptor family pyrin domain containing 3 (NLRP3) inflammasome is activated in HS platelet, which, in turn, induces platelet activation and thrombocytopenia. The study tried to clarify the activation of the NOD-like receptor signaling pathway under HS conditions and investigate its roles in mediating HS-induced thrombocytopenia. **Methods.** Rat HS models were established in a certain ambient temperature and humidity. Platelets, isolated from blood, were counted and CD62P, an index of platelet activation, was measured by flow cytometry in all rats. The colocalization of NLRP3 inflammasome in platelet was detected by confocal fluorescence microscopy. Mitochondrial-derived reactive oxygen species (ROS) was detected using the molecular probes. Plasma HMGB1 and IL-1 β levels were measured by ELISA. **Results.** Platelet activation, showed by upregulated CD62P, and thrombocytopenia were observed in HS rats. HS activated the NLRP3 inflammasome, which was induced by elevated levels of ROS, while the upregulated CD62P and thrombocytopenia triggered by NLRP3 inflammasome were attributed to the high mobility group box protein 1 (HMGB1) in plasma. Moreover, inhibition of the NOD-like receptor signaling pathway in rats with HS suppressed platelet activation and the decline of platelet count. Similar results were obtained when the receptor toll-like receptor 4 (TLR4) / advanced glycation end product (RAGE) was blocked. **Conclusions.** The NOD-like receptor signaling pathway induces

platelet activation and thrombocytopenia in HS rats. These findings suggested that the NLRP3 inflammasome might be the potential target for HS treatment.

27 Abstract

28 **Background.** Thrombocytopenia, an early common complication in heatstroke (HS), has been
 29 widely considered as a mortality predictor of HS. The mechanism underlying thrombocytopenia
 30 in HS remains unknown. It is not known whether NOD-like receptor family pyrin domain
 31 containing 3 (NLRP3) inflammasome is activated in HS platelet, which, in turn, induces platelet
 32 activation and thrombocytopenia. This study tried to clarify the activation of the NOD-like
 33 receptor signaling pathway under HS conditions and investigate its roles in mediating HS-
 34 induced thrombocytopenia.

35 **Methods.** Rat HS models were established in a certain ambient temperature and humidity,
 36 Platelets, isolated from blood, were counted and CD62P, an index of platelet activation, was
 37 measured by flow cytometry in all rats. The colocalization of NLRP3 inflammasome in platelet
 38 was detected by confocal fluorescence microscopy. Mitochondrial-derived reactive oxygen
 39 species (ROS) was detected using the molecular probes. Plasma HMGB1 and IL-1 β levels were
 40 measured by ELISA.

41 **Results.** Platelet activation, showed by upregulated CD62P, and thrombocytopenia were
 42 observed in HS rats. HS activated the NLRP3 inflammasome, which was induced by elevated
 43 levels of ROS, while the upregulated CD62P and thrombocytopenia triggered by NLRP3
 44 inflammasome were attributed to the high mobility group box protein 1 (HMGB1) in plasma.
 45 Moreover, inhibition of the NOD-like receptor signaling pathway in rats with HS suppressed
 46 platelet activation and the decline of platelet count. Similar results were obtained when the
 47 receptor toll-like receptor 4 (TLR4) / advanced glycation end product (RAGE) was blocked.

48 **Conclusions.** The NOD-like receptor signaling pathway induces platelet activation and
 49 thrombocytopenia in HS rats. These findings suggested that the NLRP3 inflammasome might be
 50 the potential target for HS treatment.

Background

Heatstroke (HS) is a life-threatening condition characterized by a core body temperature over 40.5°C (Epstein & Yanovich, 2019). which was often complicated with multiple organ dysfunction syndrome (MODS) and even multiple organ failure (MOF), including acute hepatic failure (AHF), acute renal failure, disseminated intravascular coagulation (DIC), (Hifumi et al., 2018). Every few years, the deadly heat wave occurs and leads to thousands of deaths from HS (Gaudio & Grissom, 2016).

During the past few decades, evidences suggest that multi-organ damage correlates with the development of systemic inflammatory response syndrome (SIRS) that is stimulated by cytokines and other immune modulators in HS (Epstein & Yanovich, 2019). Platelets, mainly involved in hemostasis and thrombosis, also play important roles as inflammatory cells in innate and adaptive immune responses, which is possibly involved in the SIRS in HS (Hifumi et al., 2018;Vieira-de-Abreu et al., 2012; Semple et al., 2011). Importantly, thrombocytopenia, one of the most common complications frequently occurring early within 24 h after HS onset, has been taken as a good predictor of HS-related mortality (Fan et al., 2015). However, how about the pathophysiological responses of platelet and the pathogenesis of thrombocytopenia are to be elucidated in HS.

NOD-like receptor family pyrin domain containing 3 (NLRP3) inflammasome has been extensively investigated in the processes of dysbalanced inflammation and coagulation cascade (Qiao et al., 2018). NLRP3 inflammasome contributed to platelet activation and aggregation, and thrombosis via activating caspase-1 within inflammasome complexes (Murthy et al., 2017; Qiao et al., 2018). Hottz et al. found NLRP3 inflammasome was activated to release increased interleukin-1 β (IL-1 β) in activated platelets, with increased expression of P-selectin (CD62P), which is associated with thrombocytopenia in patients with dengue fever (Hottz et al., 2013). IL-1 β , an important inflammatory factor mediated by NLRP3-dependent caspase-1 activation, is linked to increased endothelial permeability (Bozza et al., 2008), thrombosis, and dysregulated

hemostasis in dengue fever ([Qiao et al., 2018](#)). What's more, significantly increased IL-1 β levels have been found in HS ([Geng et al., 2015](#)).

High mobility group box protein 1 (HMGB1), a typical damage-related molecular pattern molecule, is often transferred from the nucleus to the cytoplasm and can be extracellularly released under many stimuli ([Kang et al., 2014](#)). We have previously demonstrated that early elevated plasma levels of HMGB1 prognosed the severity and mortality in patients with HS ([Tong et al., 2011](#)). More importantly, Gen et al. found that HS induced liver dysfunction via HMGB1-induced activation of NLRP3 inflammasome and IL-1 β release ([Geng et al., 2015](#)). It is well known that HMGB1 plays roles in regulating platelet activation, microparticle secretion and adhesion, and thrombus formation ([Vogel et al., 2015](#); [Vallance et al., 2017](#)). Moreover, mice lacking HMGB1 in platelets exhibited increased bleeding time, reduced thrombus formation, platelet aggregation, inflammation, and organ damage during experimental trauma/hemorrhagic shock ([Vogel et al., 2015](#)). Unfortunately, whether HMGB1-induced activation of NLRP3 inflammasome is involved in platelet activation and thrombocytopenia in HS is to be elucidated.

In this study, using a rat model of HS, we tried to investigate whether HMGB1-induced activation of NLRP3 inflammasome occurs via its receptors including toll-like receptor 4 (TLR4) and the receptor for advanced glycation end product (RAGE) signaling pathway, and contributes to platelet activation and thrombocytopenia.

Materials & Methods

Experimental animals

Because estrogen has certain effects on HS pathogenesis and organ injury ([Chen et al., 2006](#)), only adult male, pathogen-free Sprague-Dawley (SD) rats (Experimental Animal Center of the General Hospital of Southern Theatre Command, license number for animal experimentation: SCXK, GuangDong 2016-0041), weighing 220 to 250 g, were used in this study. The rats received humane care according to the criteria outlined in the Guide for the Care and Use of Laboratory Animals (National Institutes of Health publication 86-23, 1985 revision). We adhered to the guidelines for animal care of the General Hospital of Southern Theatre Command. The animal ethics committee of the General Hospital of Southern Theatre Command of PLA approved this study.

Rat model of HS

Rats housed for 6 h at ambient temperature (25°C \pm 0.5°C) with a humidity of 35% \pm 5%,

126 rats were randomly divided into 21 groups, with 6 rats per group. Animals have free access to standard food and water. To induce HS, rats were placed in a prewarmed incubator maintained at $39.5^{\circ}\text{C} \pm 0.2^{\circ}\text{C}$ with a relative humidity of $60.0\% \pm 5.0\%$. The rectal temperature (Tr) was monitored at 10-min intervals using a thermocouple (BW-TH1101; Biowill, Shanghai, China), which was inserted 5.5 cm into the rectum of each rat. The time point at which the Tr reached 43°C was considered a reference point of HS onset (*Geng et al., 2015*). The rats were removed from the incubator after HS onset, transferred to room temperature ($22.0^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$), and fed with adequate food and water. The rats in control group were sham-heated at a temperature of $25^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$ and a humidity level of $35\% \pm 5\%$. Ethyl pyruvate (EP, 50 mg/kg body weight, MCE, USA) was injected intraperitoneally (i.p.) to inhibit HMGB1 release, or the same volume phosphate buffered solution (PBS) were injected as a negative control before rats subjected to heat stress. A neutralizing antibody specific for rats against HMGB1 (3 mg/kg body weight, Santa Cruz Biotechnology, Santa Cruz, CA, USA) was immediately injected i.p. into the rats before heat stress. In some rats, TLR4 neutralizing antibody specific for rats (8 $\mu\text{g}/\text{kg}$ body weight, Abcam, Cambridge, MA, USA), RAGE neutralizing antibody (80 $\mu\text{g}/\text{kg}$ body weight, R&D, USA), or both were injected i.p. before rats subjected to heat stress. Other rats were injected i.p. with Ac-Tyr-Val-Ala-Asp-chloromethylketone (ac-YVAD-cmk, 0.3 mg/kg body weight, Enzo Biochem Inc, New York, USA) which is the caspase-1 inhibitor or PBS containing 2.8% dimethyl sulfoxide (DMSO) as a control before rats subjected to heat stress. Some rats were given MCC950 (20 mg/kg body weight, Selleckchem, Houston, TX, USA), a specific blocker of NLRP3, 1 h before heat stress. Some rats were injected i.p. with the antioxidant N-acetylcysteine (NAC, 300 mg/kg body weight, MCE) immediately before heat stress. At the end of the experiment, rats were anesthetized by inhalation of isoflurane, and sacrificed to collect blood from abdominal aorta.

Platelet count

50 μL of whole blood was collected into a sodium citrate anticoagulation tube to measure the platelet count using a blood cell analyzer (BC-3000, Mairui, Shenzhen, China).

143 *Platelet isolation*

144 Platelets were isolated as described previously ([Qiao et al., 2018](#)). Briefly, 3 mL of
145 anticoagulant blood samples were centrifuged at 150 g for 15 min to obtain platelet-rich plasma
146 (PRP), and about 3/4 of the PRP was carefully pipetted into 2 volumes of modified Tyrode
147 buffer (12 mM NaHCO₃, 138 mM NaCl, 5.5 mM glucose, 2.9 mM KCl, 2 mM MgCl₂, 0.42 mM
148 NaH₂PO₄, 10 mM HEPES, pH 7.4). The mixture was centrifuged at 37°C at 500 g for 8 min in
149 the presence of PGE1 (0.1 µg/mL, Cayman Chemical) and apyrase (1 U/mL, Sigma-Aldrich),
150 washed twice with CGS buffer (120 mM sodium chloride, 12.9 mM trisodium citrate, 30 mM D-
151 glucose, pH 6.5), and resuspended in modified Tyrode buffer.

152 *Transmission electron microscopy examination*

153 One volume of PRP prepared above was added into 45 volumes of 3% glutaraldehyde and
154 to stand for 4 h. The samples were centrifuged at 800g for 10 minutes and the supernatant was
155 discarded. The pellet was washed with 0.1 M phosphate buffer for twice, postfixed with 1%
156 osmium tetroxide at 4°C for 1 h, and dehydrated in a graded ethanol series and embedded in
157 Epon. Epon-embedded platelets were cut into sections (70-80 nm) with an Ultracut UCT
158 ultramicrotome, transferred to copper grids, and stained with uranyl acetate and lead citrate. The
159 sections were then observed with transmission electron microscope (TEM) (H-7560, Hitachi,
160 Japan).

161 *Flow cytometric analyses*

162 Freshly isolated platelets (10⁶ to 10⁷) were resuspended in 1 mL of modified Tyrode buffer,
163 and treated with 0.2% triton before to measure intracellular cytokines. A minimum of 10,000
164 events per gate was acquired using a flow cytometer (BD LSR Fortessa). P-selectin (CD62P)
165 was determined using the anti-CD62P monoclonal antibody (1:1000, Biolegend, USA), and
166 TLR2 (toll-like receptor 2), TLR4, and RAGE were assessed with antibodies targeted to TLR2
167 (1:500, Abcam), TLR4 (1:1000, Abcam), and RAGE (1:1000, Abcam). NLRP3 expression was
168 evaluated by an NLRP3 antibody (1:1000, Abcam), and activation of caspase-1 was assessed by
169 the fluorescent probe green fluorescent-labeled inhibitor of caspase-1 (FLICA, 1:100,
170 Immunochemistry Technologies, Bloomington, MN), which irreversibly binds to activated
171 caspase-1. IL-1β was evaluated by the anti-IL-1β antibody (1:1000, Biorbyt). Mitochondrial-
172 derived reactive oxygen species (ROS) were detected using the molecular probes Mito-SOX (for
173 mitochondria O₂•⁻, 1:1000, Invitrogen), DHE (for cytoplasmic O₂•⁻, 1:1000, Invitrogen), and
174 DCF-DA (for H₂O₂, 1:1000, Invitrogen). All indices were doubly labeled with a phycoerythrin-
175 or fluorescein isothiocyanate-conjugated CD61 monoclonal antibody (1:1000, Biolegend) to
176 label platelets. The results were analyzed using FlowJo software 7.6.

177 *Confocal fluorescence microscopy*

Immunofluorescence for NLRP3 and apoptosis-associated speck-like protein containing a caspase-recruitment domain (ASC) was performed according to previous research (Feng et al., 2018). Platelets attached on a poly-L-lysine-coated coverslip were fixed with pre-cooled methanol for 20 min, washed twice with PBS (135 mM NaCl, 4.7 mM KCl, 10 mM Na₂HPO₄, 2 mM NaH₂PO₄, pH 7.4), and blocked with 10% fetal calf serum (FCS) in PBS. Then, platelets were incubated with goat anti-rat NLRP3 antibody (1:1000, Abcam) or rabbit anti-rat ASC antibody (1:500, Santa Cruz) for 30 min, washed twice with PBS, and labeled with corresponding Dlight 488 and Dlight 594 conjugated secondary antibodies (1:1000, Invitrogen) for 30 min respectively. Preparations were analyzed under a laser scanning confocal microscope (Fluo View FV1000, Olympus), and FV1000 operations software was used for recording.

Plasma HMGB1 and IL-1 β levels measurement

According to the manufacturer's instructions, plasma HMGB1 levels were measured by a commercially available HMGB1 enzyme-linked immunosorbent assay kit (Shino-Test Corporation, Sagamihara, Japan), and IL-1 β levels were measured by a commercially available IL-1 β enzyme-linked immunosorbent assay kit (Invitrogen, America).

Statistical analysis

All data were presented as the mean \pm SD unless stated otherwise. All data followed a normal distribution except for one group, which was analyzed with Kruskal-Wallis. For the data followed a normal distribution, statistical significance was determined with the least significant difference t-test or one-way analysis of variance (ANOVA). IBM SPSS Statistics 26 software was used for data. $P < 0.05$ was considered statistically significant.

Results

HS induces platelet activation and thrombocytopenia in HS rats

The platelet count began to decline at 3 h after HS onset (Fig. 1A), whereas the expressions of IL-1 β (Fig. 1D) and CD62P (Fig. 1E) in platelets increased progressively during the same period after HS onset. All changes were peaked at 9 h after HS onset. The platelet parameters such as mean platelet volume (MPV) and platelet distribution width (PDW) were assessed. MPV (Fig. 1B) and PDW (Fig. 1C) at 3 h and 6 h after HS maintained in normal ranges, with no statistical differences comparing to the sham group. However, both MPV and PDW at 9 h after HS increased significantly compared to those in the control group after 9 h of HS ($P < 0.01$). Therefore, for the remaining experiments, we observed heat-stressed animals only at the time

209 point of 9 h after HS onset.

210 *NLRP3 inflammasome activation in platelets in HS rats*

211 The association of NLRP3 and ASC as well as caspase-1 represents activation of the
212 inflammasome. The colocalization of NLRP3 (green) and ASC (red) in platelets was observed
213 under a confocal microscopy (Fig. 2C). In addition, flow cytometric analyses showed that
214 NLRP3 (Fig. 2A) and cleaved caspase-1 (Fig. 2B) increased at 3 h and reached the peak levels at
215 9 h after HS onset. All results indicate the HS-inducing NLRP3 inflammasome activation in
216 platelets.

217 *NLRP3 inflammasome mediates platelet activation and thrombocytopenia in HS rats*

218 To investigate whether HS-activated NLRP3 inflammasome mediates platelet activation
219 and thrombocytopenia, we injected rats i.p. with MCC950, a specific inhibitor of the NLRP3
220 inflammasome, before the rats subjected to heat stress. The results showed that inhibited NLRP3
221 inflammasome significantly down-regulated the levels of cleaved caspase-1 (Fig. 3A), IL-1 β
222 secretion (Fig. 3B) and CD62P expression (Fig. 3C) and reduced the drop of platelet count (Fig.
223 3D) at 9 h after HS onset. Moreover, pharmacological inhibition of caspase-1 activity with ac-
224 YVAD-cmk also markedly down-regulated the IL-1 β secretion (Fig. 3E) and CD62P expression
225 (Fig. 3F) as well as the drop of platelet count (Fig. 3G) at 9 h after HS onset.

226 *HMGB1 activates platelet NLRP3 inflammasome in HS rats*

227 Previous studies found that early increased extracellular HMGB1 levels in HS were
228 negatively correlated with its prognosis ([Tong et al., 2013](#)). HMGB1 activates the NLRP3
229 inflammasome in liver cells, which in turn promotes hepatocyte pyroptosis ([Geng et al., 2015](#)).
230 Consistent with previous studies ([Tong et al., 2011](#)), we found that plasma HMGB1
231 concentrations in HS rats were gradually increased (Fig. 4A). We also unraveled the role of
232 HMGB1 in inducing NLRP3 inflammasome activation, platelet activation, and
233 thrombocytopenia in HS. We injected rats i.p. with EP to inhibit HMGB1 release and used anti-
234 HMGB1 neutralizing antibody to block the effect of HMGB1 before submitting rats to HS.

235 EP inhibiting or neutralizing antibody against HMGB1 significantly reduced the expression
236 of NLRP3 (Fig. 4B) and cleaved caspase-1 (Fig. 4C) at 9 h after HS onset. Notably, levels of
237 secreted IL-1 β (Fig. 4D), expression of CD62P (Fig. 4E), and thrombocytopenia (Fig. 4F) at 9 h
238 after HS onset were significantly alleviated after pretreatment with EP and anti-HMGB1
239 antibody. These results indicate that HMGB1 plays an important role in activating NLRP3

inflammasome and possibly participates in platelet activation and thrombocytopenia in HS.

In the early stages of sterile inflammation, HMGB1 activates the NLRP3 inflammasome through TLR4 or RAGE receptors (Xu et al., 2013). As shown in Figures 4G-I, expressions of TLR2, TLR4, and RAGE in platelets were gradually increased after HS onset. To define the receptors that mediate HMGB1-induced NLRP3 inflammasome activation, we applied anti-TLR4 and anti-RAGE neutralizing antibodies before heat exposure. Either anti-TLR4 or anti-RAGE neutralizing antibody significantly inhibited HS-induced NLRP3 (Fig. 4J) and cleaved caspase-1 (Fig. 4K) expression in platelets at 9 h after HS onset. In addition, the combination of anti-TLR4 and anti-RAGE neutralizing antibody induced greater inhibition of NLRP3 and cleavage of caspase-1 expression. Synchronous changes were also observed in HMGB1-induced upregulated expression of IL-1 β (Fig. 4L), and thrombocytopenia (Fig. 4N) at 9 h after HS. Anti-TLR4 or anti-RAGE neutralizing antibody inhibited HS-induced CD62P expression, while combination of anti-TLR4 and anti-RAGE neutralizing antibody made no significantly effect compared with single neutralizing antibody (Fig. 4M). These data indicate that HMGB1 activates NLRP3 inflammasome via both TLR4 and RAGE receptors, which is possibly associated with platelet activation and thrombocytopenia in HS.

HMGB1 activates platelet NLRP3 inflammasome by upregulating ROS in HS rats

ROS mainly includes the superoxide anion (O₂⁻), hydrogen peroxide (H₂O₂), and the hydroxyl radical (HO⁻) (Leytin et al., 2012). Many studies confirmed HMGB1 could up-regulate ROS (Tsung et al., 2007; Pietraforte et al., 2014), which was the key to activate NLRP3 inflammasome (Dostert et al., 2008; Zhou et al., 2011). To study the changes of ROS in platelets and the effects of ROS on the HMGB1-induced NLRP3 inflammasome in HS, we used a fluorescence probe to detect the expression of mitochondrial O₂⁻, cytoplasmic O₂⁻, and H₂O₂ in platelets in HS rats. We found that mitochondrial O₂⁻ (Fig. 5A), cytoplasmic O₂⁻ (Fig. 5B), and H₂O₂ (Fig. 5C) increased at 3 h after HS onset. Inhibiting HMGB1 significantly reduced the level of ROS, which indicated that HMGB1 was involved in high-level of ROS in HS (Fig. 5D-F).

To explore the relationship between ROS and the NLRP3 inflammasome activation, we pretreated rats with the antioxidant NAC. In platelets, NAC significantly inhibited the expression of NLRP3 (Fig. 5G) and cleaved caspase-1 (Fig. 5H) at 9 h after HS onset. Similar results were observed for secreted IL-1 β (Fig. 5I), CD62P expression (Fig. 5J), and thrombocytopenia (Fig. 5K). These results indicate that ROS is responsible for platelet NLRP3 inflammasome-induced activation and thrombocytopenia in HS.

273 Discussion

274 In the current study, we investigated the NOD-like receptor signaling pathway of platelet in
 275 HS rats, and explored the mechanisms involved in platelet activation and thrombocytopenia. The
 276 main results of our investigation were as following: (1) HS activated the NOD-like receptor
 277 signaling pathway, which induced thrombocytopenia and platelet activation in HS rats. (2) High
 278 levels of extracellular HMGB1, through TLR4 and RAGE pathway, induced NLRP3
 279 inflammasome activation via ROS possibly in HS rats.

280 MPV and PDW are indices of average platelet volume and variation in platelet size
 281 respectively, both of which are markers of platelet activation and thrombocytopenia
 282 ([Pogorzelska et al., 2020](#)). In this experiment, we found that MPV and PDW did not change at 3
 283 h but were increased significantly at 9 h after HS onset. Previous study showed no evidence of
 284 megakaryocyte damage ([Gader et al., 1992](#)). We found platelet aggregation gradually decreased
 285 after HS onset (Fig.SA), which consists with the results that hyperthermia inhibit platelet
 286 aggregation ([Etulain et al., 2011](#)), indicating that peripheral platelet destruction may be a
 287 possible explanation of the thrombocytopenia of HS.

288 Zhuang et al. found that heat stress facilitated the procession of Px-caspase-1 (a caspase
 289 gene) expression, an important effector molecule of the NLRP3 inflammasome ([Zhuang et al.,](#)
 290 [2011](#)). Murthy et al. found that NLRP3 inflammasome affects platelet activation, aggregation,
 291 and thrombosis ([Murthy et al., 2017](#)). Additionally, one team in our institute previously found
 292 that HMGB1-activated NLRP3 inflammasome in liver cells during HS was associated with liver
 293 damage ([Geng et al., 2015](#)). Therefore, it is speculated that the HMGB1-activated NLRP3
 294 inflammasome possibly mediates platelet activation and thrombocytopenia in HS. We observed
 295 that the expressions of NLRP3, ASC, and cleaved caspase-1 in platelets of HS rats were
 296 increased at early stage after HS onset and remained increased thereafter (Fig. 2A, B, C). All
 297 these results reflect the assembly and activation of NLRP3 inflammasome in HS. Consistent with
 298 the results of a previous study ([Murthy et al., 2017](#)), we found that inhibiti NLRP3 and
 299 cleavage of caspase-1 alleviated platelet activation and thrombocytopenia (Fig. 3), indicating that
 300 the NLRP3 inflammasome played an important role in platelet activation and thrombocytopenia
 301 possibly.

HMGB1, a class of non-histone chromosomal binding protein presenting in eukaryotic cells, has been extensively studied as an important molecule activating NLRP3 inflammasome (Park et al., 2006). Our previous studies showed that plasma HMGB1, significantly elevated at an early stage in HS patients, was associated with more critical disease and poor prognosis (Tong et al., 2011). Inhibiting HMGB1 release or blocking HMGB1 alleviated liver sinusoidal endothelial damage (Tong et al., 2013) and reduced thrombosis in HS (Murthy et al., 2017). In this experiment, we also found that inhibiting HMGB1 by EP and anti-HMGB1 neutralizing antibody down-regulated the activation of the NLRP3 inflammasome, platelet activation, and thrombocytopenia. Previous studies have showed that HMGB1 promotes inflammation via the main receptors including TLR2, TLR4 and RAGE receptors (Park et al., 2006), TLR4-dependent upregulation of the platelet NLRP3 inflammasome promotes platelet aggregation (Vogel et al., 2019). Because there was no anti-TLR2 neutralizing antibody for rats, we only tested the effects of TLR4 and RAGE receptors. Different to the results of a prior study that visfatin-induced disruption on junction proteins of mouse vascular endothelial cells was conducted through the HMGB1-RAGE rather than the HMGB1-TLR4 pathway (Chen et al., 2015), our results indicate that both TLR4 and RAGE receptor-specific antibodies can inhibit NLRP3 inflammasome activation, platelet activation and thrombocytopenia. Also, anti-TLR4 antibody pretreatment significantly shortened the heat exposure time of rats (Fig.SB). These results suggest that HMGB1 activates the NLRP3 inflammasome via TLR4 and RAGE receptors and participates in platelet activation and thrombocytopenia possibly.

ROS, taking an important role in the homeostasis of aging and death of platelets (Pietraforte et al., 2014), are involved in platelet activation, adhesion, and aggregation and apoptosis (Leytin et al., 2012). Consistent with previous studies, 3 kinds of ROS in the platelets of rats with HS increased progressively with time (Fig. 5A, B, C) in our experiments. HMGB1 can upregulate intracellular levels of ROS in many diseases including HS (Tang et al., 2011). Similarly, we found inhibition or blockade of HMGB1 could partially inhibit the production of all the 3 kinds of ROS (Fig. 5D, E) in HS rats. It was found that HMGB1-induced elevated intracellular ROS (Abais et al., 2011; Han et al., 2015) could promote NLRP3 inflammasome activation. We found that NAC pretreatment could inhibit the expression of platelet NLRP3 and cleaved caspase-1 as well as platelet activation and thrombocytopenia in HS rats, indicating that ROS could activate NLRP3 inflammasome in platelets and may be involved in thrombocytopenia.

Pyroptosis is a caspase-1 dependent programmed cell death (Geng et al., 2015). In the current study, thrombocytopenia and active caspase-1 showed opposite trends, suggesting that there must be a link between them. Recent studies have shown that pyroptosis is a major cell

death pathway of platelets treated with dengue virus and envelope protein domain III (Lien et al., 2021). Using different methods to validate the pyroptotic results, they they examined cleaved caspase-1, cleaved GSDMD and cell-surface GSDMD levels, IL-1 β and lactic dehydrogenase release (Lien et al., 2021). However, we did not conduct experiments to verify pyroptosis in platelet of HS. whether pyroptosis is a kind of cell death pathway of platelets in the HS rat model need further research. In addition, we did not exclude the effect of direct thermal injury to the platelet. Furthermore, other signaling pathways in platelet may also be activated and involved in the inflammation process. Finally, our results did not fully reflect the effect of NLRP3 inflammasome on HS platelets for using rat models not patients.

Conclusions

In conclusion, this study preliminarily demonstrates that elevated extracellular HMGB1 induced high levels of ROS via both TLR4 and RAGE receptors of platelets, which in turn participates NLRP3 inflammasome activation leading to thrombocytopenia in HS rats. The recognition of this study may aid to develop novel therapeutic agents in future.
