Myths in Psychology are beliefs that are widely spread and inconsistent with the empirical evidence available within this field of knowledge. They are characterized by being relatively stable, resistant to change, and prevalent both among the non-academic population and among students and professionals within this discipline. The aim of this study was to analyse the prevalence of these myths among Spanish psychology students and the influence of three variables: the type of university, face-to-face (UAM) and online (UNED), the academic year in which participants were enrolled and familiarity with scientific dissemination. Results show that participants from the face-to-face university, enrolled in higher academic years and that reports familiarity with scientific dissemination believe less in myths than those from the online university, enrolled in lower years and that report no familiarity with scientific dissemination.

Abstract

19 Myths in Psychology are beliefs that are widely spread and inconsistent with the empirical evidence
20 available within this field of knowledge. They are characterized by being relatively stable, resistant to
21 change, and prevalent both among the non-academic population and among students and professionals
22 within this discipline. The aim of this study was to analyse the prevalence of these myths among Spanish
23 psychology students and the influence of three variables: the type of university, face-to-face (UAM) and
24 online (UNED), the academic year in which participants were enrolled and familiarity with scientific
25 dissemination. Results show that participants from the face-to-face university, enrolled in higher
26 academic years and that reports familiarity with scientific dissemination believe less in myths than those
27 from the online university, enrolled in lower years and that report no familiarity with scientific
28 dissemination.

29 **Keywords:** myths in psychology, higher education, academic year, scientific dissemination.

30 Myths in Psychology are defined as beliefs about human behavior that are inconsistent with the
31 available scientific evidence but that exhibit great social support (Lilienfeld et al., 2010;
32 Stanovich, 1992). Contrary to certain expectations, these misconceptions are not only believed
33 by people outside of Psychology, but also prevail among professionals within this discipline
34 (Fasce & Adrián-Ventura, 2020; Furnham & Hughes, 2014; Galassi & Gersh, 1993; Hooper,
35 2006; Houben et al., 2019; Lilienfeld et al., 2013; Torres, Boccacini & Miller 2006). Although
36 some studies show that university studies reduce the belief in myths (Bensley, Lilienfeld &
37 Powell, 2014; Hughes et al., 2015; Sibicky, Klein & Embrescia, 2020), it has also been shown
38 that having university studies does not eliminate the belief in myths nor are these beliefs fully
39 replaced with explanations from scientific psychology (Hughes et al., 2015; Lyddy & Hughes,
40 2012; Root & Stanley, 2017). On many occasions, students who begin their studies in
41 Psychology have imprecise and contradictory information about human behavior (Hughes,
42 Lyddy & Lambe, 2013). The resistance to change that characterizes these ideas is due to a
43 history of intermittent and repeated exposure to these false facts through socializing agents such
44 as the media, family or peers (Furnham & Hughes, 2014; Kowalski & Taylor, 2004). This favors
45 the creation of a confirmation bias when presented with new information (Furnham & Hughes,
46 2014; Kowalski & Taylor, 2004). In this way, most popular knowledge is not disproven and
47 cannot be replaced by more adjusted beliefs (Lilienfeld et al., 2010; Stanovich, 1992), which
48 leads, in many cases, to its consequences reaching the professional practice of those students
49 who complete this stage of education (Furnham & Hughes, 2014).

50 Believing that some erroneous statements in psychology are true is not a trivial phenomenon and
51 can lead to serious negative effects, such as the implementation of harmful practices in
52 educational or clinical areas, for example (Lilienfeld et al., 2010). The belief in myths also

53 hinders the development of learning content related to the discipline and critical thinking within
54 and outside of Psychology (Lilienfeld et al., 2010). It can even legitimize existing inequalities in
55 society, such as the differences between men and women, the stigma towards people with mental
56 health problems, or the consequences that derive from the naturalistic fallacy (i.e., where
57 everything natural is desirable and, therefore, unchangeable) (Lester, Strunk & Hoover, 2020;
58 Lilienfeld et al., 2010).

59 The study of misconceptions in Psychology began in the second decade of the 20th century (e.g.,
60 Nixon, 1925, see also Tupper & Williams, 1986). Since then, numerous studies have been
61 carried out, either by reviewing myths in different general areas of Psychology (e.g., Lilienfeld et
62 al., 2010) or by focusing on more specific aspects of the discipline, such as myths about
63 schizophrenia (Furnham & Bower, 1992), ontological development and neuropsychology
64 (Furnham, 2018; Furnham & Grover, 2019), intelligence (Warne, Astle & Hill, 2018) or
65 behavior analysis (Lamal, 1995). However, the study of myths is not limited to behavioral
66 science. The prevalence of myths has been studied in fields such as Education (Ferrero, Garaizar
67 & Vadillo, 2016), Medicine (Kaufman et al., 2013) or public health policies (Viehbeck,
68 Petticrew & Cummins, 2015), as well as in science as a knowledge system (McComas, 1996),
69 and the practical consequences that they entail, such as those caused by the myths of
70 mathematics in their students (Powell & Nelson, 2021).

71

72 **Relevant factors in the belief in myths in Psychology**

73 Several studies show that the progression of the students in psychology education. measured with
74 variables such as the academic year or the course credits earned, is related to the prevalence of

75 myths in the field of Psychology. For example, a positive relationship has been found between
76 academic history and the recognition of myths as such, in addition to a greater predisposition to
77 abandon this type of beliefs (Bensley, Lilienfeld & Powell, 2014; Gardner & Brown, 2013;
78 Gardner & Dalsing, 1986; Gaze, 2014). This effect has been found in pre-post (e.g., Taylor &
79 Kowalsky, 2004, 2009), cross-sectional (e.g., Amsel, Baird, & Ashley, 2011; Gardner & Dalsing,
80 1986) and longitudinal design (McCarthy & Frantz, 2016).

81 Some studies suggest that psychology students are better at recognizing the myths in this
82 discipline than the general population or students from other university degrees (Bensley,
83 Lilienfeld & Powell, 2014; Furnham & Hughes, 2014; Gardner & Dalsing, 1986; Hughes et al.,
84 2015; Sibicky, Klein & Embrescia, 2020). Reaching a higher academic year could indicate a
85 greater interest in the discipline, and with it, a greater desire to further delve into psychology
86 (Furnham & Hughes, 2014). However, although there is a decrease in the belief in myths
87 according to academic year these preconceptions do not always disappear completely
88 (Aleksandrova-Howell et al., 2020; Brown, 1983; Gaze, 2014). For example, Gardner and
89 Dalsing (1986) found that a change only occurs when the person has participated in psychology-
90 related courses to the subject of between 19 and 70 hours. In other cases, such as that of
91 Vaughan's study (1977), it was found that university students from different degrees started, on
92 average, defending 40% of a series of misconceptions about Psychology. Upon completion of an
93 Introductory Psychology Course at university, participants reduced their misconceptions by only
94 5.5% (Vaughan, 1977). Although none of the studies explicitly state the contents of these
95 introductory courses, which may be a relevant limitation, the results that indicate a relative
96 reduction of these misconceptions seem to be replicated in other studies (McCarthy & Frantz,
97 2016; Root & Stanley, 2017). This accumulation of evidence on the decline in myth belief is an

98 indication of the benefits, although limited, that formal education seems to grant as the student
99 progresses through the degree (Furnham & Hughes, 2014; Gardner & Dalsing, 1986; Hughes et
100 al., 2015).

101 The type of university can also be a relevant factor to consider. The different types of
102 universities can be differentiated, mainly, through their teaching modality: face-to-face or online
103 (Harmon & Lambrinos, 2006; Zhao et al., 2005). Each teaching modality can attract different
104 types of students. A common practice in the study of myths among the university population has
105 consisted in recruiting students without considering differences according to degree or university
106 in which these higher studies take place (e.g., see Furnham & Bower, 1992; Gardner & Brown,
107 2013; Vaughan, 1977), to maximize external validity. However, there may be more differences
108 than similarities between students from different university backgrounds. For example, the
109 profile of the average student in a face-to-face public university such as the Autonomous
110 University of Madrid (UAM) is usually that of a young adult between the ages of 18 and 24, who
111 is completing their first undergraduate program, without any added family or work
112 responsibilities (Autonomous University of Madrid, 2019). In contrast, the profile of the average
113 student from a public online learning university, such as the National Distance Education
114 University (UNED) responds to that of an adult, with full-time work, greater family
115 responsibilities and previous studies, who seeks to improve their professional skills (García
116 Aretio, 2006). Regarding age, undergraduate students between 23 and 49 years old tend to
117 choose online universities to pursue an undergraduate program (Stewart, Bachman & Johnson,
118 2010). Such students tend to work more hours weekly than those who choose face-to-face
119 education (Dutton, Dutton & Perry, 2002; Jenkins & Downs, 2003; Mattes, Nanney & Coussans-
120 Read, 2003) and tend to have children and family responsibilities (Conklin, 1997; Dutton, Dutton

121 & Perry 2002; Grimes & Antworth, 1996) In this way, each university could contribute a
122 different student profile and, therefore, could show differences in the belief in misconceptions
123 within Psychology. These variations have not been explored in previous studies and could be
124 relevant in the study of myths in Psychology.

125 Familiarity with scientific dissemination is another factor that may influence the belief in myths.
126 It can be understood as "the use of appropriate skills, media, activities and dialogue to produce
127 one or more of the following personal responses to science: awareness, enjoyment, interest,
128 opinion-forming and understanding" of scientific knowledge (Burns, O'Connor & Stocklmayer,
129 2003). There are various formats for its use, but not all of them or their contents are equally
130 adequate. While reading academic literature can help reduce belief in myths (Furnham, Callahan
131 & Rawles, 2003), familiarity with content on the Internet can be harmful (e.g., Putnam, 2011).
132 This is due, at least in part, to the absence of supervision mechanisms that guarantee that the
133 informative material on the internet transmits information following the scientific evidence
134 available (Lewandowsky et al., 2012). Also, non-expert psychologists could have difficulties
135 distinguishing scientific vs pseudo-scientific dissemination (see Lilienfeld, Ammirati and David,
136 2012) which could result not only to not reduce the belief in myths, but increasing it. In
137 addition, scientific dissemination can oversimplify scientific facts to make them more accessible
138 to a non-specialized audience, which can lead to misunderstanding research advances and
139 promoting belief in myths (Lewandowsky et al., 2012; Cassany, López & Martí, 2000). Finally,
140 disseminating false scientific information on social networks can increase its acceptance as
141 correct information simply due to the mere repeated exposure to it, as occurs in other more
142 conventional media (Begg Anas & Farinacci, 1992; Furnham, Callahan & Rawles, 2003).

143 **The methodology used in the evaluation of myth belief**

144 To reduce the prevalence of belief in psychological myths, it is first necessary to adequately
145 detect what these myths are, who believes them and how much they believe in them. This is only
146 possible with valid and reliable evaluation methods. However, many studies in this line of
147 research do not report the psychometric properties of their tools, which may affect the
148 generalization of the results when it comes to reliability and validity (Prieto & Delgado, 2010).

149 When studying the prevalence of myths and misconceptions in Psychology, self-report
150 questionnaires have been the default choice as they are a set of tools that allow participants to
151 express both their (dis)agreement and the extent to which they believe that certain statements are
152 true (Bensley & Lilienfeld, 2017; Bensley, Lilienfeld & Powell, 2014; Hughes, Lyddy & Lambe,
153 2013). In this regard, previous literature discusses the relevance of methodological factors such
154 as the response format, content, and psychometric properties of the questionnaires, as well as the
155 characteristics of the samples used in the estimation of myths (Bensley & Lilienfeld, 2017;
156 Hughes, Lyddy & Lambe, 2013; Taylor & Kowalski, 2012). These methodological factors may
157 have influenced how the research was conducted so far, specifically in terms of potential biases
158 (Taylor & Kowalski, 2012).

159 The dichotomous response format (true/false) has been, for many years, the chosen by
160 researchers (Basterfield et al., 2020; Brown, 1983; Ferrero, Garaizar & Vadillo, 2016; Furnham,
161 Callahan & Rawles, 2003; Gardner & Dalsing, 1986; Hughes, Lyddy & Lambe, 2013; Kowalski
162 & Taylor, 2004; Lamal, 1995; Taylor & Kowalski, 2004, 2012; Torres, Boccacini & Miller,
163 2006; Vaughan, 1977). This format is associated with a series of limitations (Bensley &
164 Lilienfeld, 2017; Griggs & Ransdell, 1987; Hughes, Lyddy & Lambe, 2013). One of them is the
165 acquiescence bias, where participants always respond with an affirmative answer (Bensley &
166 Lilienfeld, 2017), thus recommending that the formulation of the statements should be divided

167 into direct and inverse items to prevent response patterns (Taylor & Kowalski, 2004; Griggs &
168 Ransdell, 1987). If all items represent myths and are worded in such a way that the correct
169 answer is “true”, the direct consequence is the overestimation of misconceptions in students as a
170 methodological artifact (Bensley & Lilienfeld, 2015; Griggs & Ransdell, 1987; Taylor &
171 Kowalski, 2012). However, not all studies have carried out this reversal process on items’
172 wording (e.g., see Gardner & Dalsing, 1986; Vaughan, 1977). When the presentation of the items
173 is balanced (i.e., it is established that approximately half of the items are direct and the other,
174 inverse), the resulting prevalence of believing in myths is lower (Brown, 1983).

175 Another limitation of the T/F format is the impossibility of distinguishing between those
176 responses that represent believing in myths and those that are the product of randomly answering
177 one of the two possible responses (Taylor & Kowalski, 2004). One way to control this
178 shortcoming has been to add “I don't know” as a third response option (Furnham, 2018;
179 Furnham, Callahan & Rawles, 2003; Gardner & Brown, 2013; Gardner & Dalsing, 1986;
180 Hughes, Lyddy & Lambe, 2013; Lamal, 1995). Although this can add some bias when evaluating
181 those who are not motivated to answer, its introduction makes it possible to discriminate what
182 the students do not know from what they assume as facts and obtain an answer instead of,
183 perhaps, not answering the item - blank (Furnham & Hughes, 2014; Furnham, Callahan &
184 Rawles, 2003). The introduction of ‘I don’t know’ response option comprises around 12-13% of
185 the responses (Gardner & Brown, 2013; Gardner & Dalsing, 1986) and reduces the estimate of
186 the prevalence of myths by 8%, which generates a closer and more realistic view of the
187 phenomenon (Gardner & Dalsing, 1986). However, there are still limitations to be solved
188 (Hughes, Lyddy & Lambe, 2013).

189 As an alternative to dichotomous T/F scales, the use of Likert-type scales is proposed in this type
190 of research (Gardner & Brown, 2013; Gardner & Dalsing, 1986; Furnham & Hughes, 2014). By
191 representing different levels of response, it is possible to discriminate with greater certainty the
192 degree of confidence that the participant has in the veracity of the statements. Several authors
193 (Furnham & Hughes, 2014; Gardner & Brown, 2013) use questionnaires with scales that frame a
194 gradient of options from "*completely false*" to "*completely true*", allowing for a greater range of
195 answers and not reducing it to a dichotomous choice. Thus, what is being measured is what the
196 participants believe in a more nuanced way than with the dichotomous response format. One
197 problem with this kind of scale is how participants use the central scores. One way is that they
198 use it to report that they do not know if statement is true or false. However, also participants could
199 used it to report that the sentence is half true. In our view, it is important to give participants the
200 option to report that they don't know about the sentence. Because this reason, we labelled the
201 central value of the scale as "don't know". As commented above, that allow a more accurate
202 measure of the participants' beliefs.

203 Others more critical with the methodology have highlighted the content of the questionnaires.
204 The inclusion of myths that are unrepresentative or irrelevant to the discipline, that are not
205 covered by introductory texts, or those that cannot be identified as such, given the available
206 evidence, can bias, in the same way, the estimation of the belief in myths (Bensley & Lilienfeld,
207 2017; Gardner & Dalsing, 1986; Griggs & Ransdell, 1987; Taylor & Kowalski, 2012).

208 Regarding the samples used, the general sample size in this type of study ranges between 100
209 and 200 participants (eg, see Bensley & Lilienfeld, 2015; Brown, 1983; Furnham & Bower,
210 1992; Gardner & Brown, 2013; Taylor & Kowalski, 2012; Vaughan, 1977). In studies that
211 involve the use of questionnaires, the use of a sample size of between 200 and 400 participants is

212 recommended to carry out an adequate psychometric analysis (Abad et al., 2011). However, their
213 characteristic, so far, has been their low homogeneity in terms of participants' population
214 (Bensley & Lilienfeld, 2015, 2017; Furnham & Hughes, 2014). The participants in this type of
215 research are usually university students from different fields of knowledge who enrol in some
216 Introductory Psychology courses (e.g., see Furnham & Hughes, 2014; Gardner & Brown, 2013;
217 Kowalski & Taylor, 2009). This may favor the generalization of the results to the general
218 population, which is a relevant objective, but makes it difficult to study the evaluation of these
219 ideas among psychology students throughout their academic career - and it is relevant to know
220 what happens within formal education. A consequence of this could be the variability presented
221 in the systematic reviews carried out so far. Hughes, Lyddy and Lambe (2013) suggest that
222 students who begin Introductory Psychology courses accept between 28% and 71% of these
223 myths. Other studies indicate a recognition that ranges between 30% to 39% of misconceptions
224 (Taylor & Kowalski, 2012).

225 Despite the extensive research on myths in Psychology in other countries -see, for example,
226 Russia (Aleksandrova-Howell et al., 2020), North America (Basterfield et al., 2020; Bensley &
227 Lilienfeld, 2017; Brown, 1983; Gardner & Brown, 2013), United Kingdom (Furnham, Callahan
228 & Rawles, 2003; Furnham & Hughes, 2014; Furnham & Grover, 2019), India (Kishore et al.,
229 2011)-, a study of the same characteristics has not yet been carried out in Spain.

230

The present study

231 The present study aims to provide empirical evidence regarding the belief in myths related to
232 Psychology among students enrolled in the Psychology undergraduate program, considering the
233 previously mentioned variables: the academic year, the university in which they are enrolled and
234 the familiarity with scientific dissemination. To do so, an adaptation of one of the available

235 methodological tools with a Likert scale format and with adequate psychometric guarantees is
236 used, in addition to a large sample size to ensure the representativeness of the phenomenon.

237 **Method**

238 **Participants**

239 A sample composed of 916 students from the Degree in Psychology from two Spanish
240 universities was used: Autonomous University of Madrid (UAM) (face-to-face, $n = 364$, 86%
241 women, aged between 17 and 55 years, $M = 20.03$, $SD = 3.58$) and National Distance
242 Education University (UNED) (online, $n = 552$, 77% women, aged between 18 to 78 years; $M =$
243 35.8 , $SD = 11.6$) (see Table 1 in the supplemental materials to consult the number of participants
244 by year and university).

245 **Procedure and Materials**

246 Data were collected through participation in the *PsInvestiga* participant recruitment system at the
247 UAM ($n = 238$) and dissemination by institutional email in both universities ($n = 678$). All
248 participants completed an online informed consent before the questionnaire.

249 An online questionnaire was sent to participants . This questionnaire measured the demographic
250 data and the belief in Psychology myths. Participants had to fill out the questionnaire
251 individually and their responses were completely anonymous. Before carrying out the task, the
252 student was informed of its purpose and the voluntary nature of their participation. A *demo* of the
253 questionnaire used can be found at this link: <https://forms.gle/6J1EkTT7S9G1iLBH7>. The
254 realization of this project, as well as the treatment of the collected data, has been approved by
255 both the Research Ethics Committee of the Autonomous University of Madrid (code CEI-95-
256 1758) and by the Ethics Subcommittee of the Faculty of Psychology from the same university.

257 **Demographic measures.** We collected the following data of each participant: age, gender, any
258 other degree previously obtained, the university in which he/she is currently studying
259 Psychology, the highest year of the degree being studied and his/her familiarity with scientific
260 dissemination. Finally, through an open-ended question, participants specified examples of
261 dissemination sources they consult.

262 **Myths in Psychology.** An adaptation of the 55-item questionnaire developed by Gardner and
263 Brown (2013) was carried out. The authors received permission to use this instrument from the
264 copyright holders. Five items were eliminated as they were considered to have little relevance or
265 representativeness for the study and 24 new items were added so that the final questionnaire
266 consisted of 74 items (see Table 2 in the supplemental materials for items excluded and included
267 in the questionnaire). The 74 items, both those used by Gardner and Brown (2013) and those
268 added by authors, were Psychology extracted statements taken from the book *50 Great Myths of*
269 *Popular Psychology* (Lilienfeld et al., 2010) accompanied by a five-point Likert-type scale,
270 ranging from 1 (*completely sure it is false*) to 5 (*completely sure it is true*), with 3 as the central
271 category (*I don't know*). To control for response bias, some items were reversed: 55.4% of the
272 items (41) were direct and the remaining 44.6% (33) were reversed. Therefore, some items were
273 formulated directly with the statement that is false according to scientific evidence and, in others,
274 the wording indicated the statement was supported by the available evidence. The content of the
275 test sampled different areas of Psychology in a balanced way. When it was presented in Spanish,
276 the standard procedure was followed for its adaptation to the language: translation from English
277 to Spanish by one of the authors, reverse translation by another co-author -from Spanish to
278 English- and a final check carried out by a native expert (independent from the study) to ensure
279 that the two English versions (the original and the back translation) were equivalent. A

280 psychometric analysis of this tool revealed a Cronbach's alpha indicator of 0.85, which indicates
281 acceptable reliability (Abad et al., 2011).

282 **Design and data processing**

283 In the present study, a cross-sectional descriptive between-subjects design was used, where the
284 dependent variable was the total score of the "Myths in Psychology" scale. This variable is
285 calculated through the sum of all the scores of each participant's responses with the recoded
286 items (those in which such transformation is required). The higher the scores on the
287 questionnaire, the greater the belief in the myths of this discipline. Three independent variables
288 were taken into account: academic year (with four levels: 1, 2, 3, & 4), type of university (with
289 two levels: face-to-face and online) and familiarity with scientific dissemination (with two
290 levels: Yes / No).

291 To explore the effect of the academic year achieved and of the profile of the Psychology student
292 on the belief in myths, a two-factor ANOVA was performed for independent samples (4x2) on
293 the DV "total score" with "year" and "type of university" as factors. On the other hand, a
294 Student's t-test was performed to analyze the effect of the familiarity with scientific
295 dissemination on the prevalence of these beliefs. It was not incorporated into the previous
296 analysis of variance because of the limitations associated with the number of participants who
297 indicated familiarity with scientific dissemination and the impact it has on the assumptions of the
298 statistical model.

299 Following the recommendations on the dissemination of scientific data (e.g., see Björk et al.,
300 2010; Frankenhuis & Nettle, 2018), the database obtained and used in this study is published on
301 the Open Science Framework platform and is available to any researcher who wishes to consult
302 them at the following link: <https://osf.io/tazg9/>.

303

Results

304 **Descriptives.** The descriptive statistics for the items of the *Myths in Psychology* questionnaire
305 can be found in Table 1, recoded and ordered from highest to lowest score. The graphs of the
306 relative frequencies of items in the total sample can be found in Figures 1-4 in the supplemental
307 materials. The mean of the assessment at item-level across the total sample was 2.62 ($SD = 0.16$).
308 If the data were differentiated according to the type of university, in the face-to-face one there
309 was a value of 2.39 ($SD = 0.82$) and, in the online one 2.79 ($SD = 0.15$).

310 As mentioned, each participant could evaluate each item on a 1-5 scale. We identified means
311 around 4 and 5 [>3.5] (*I think it is true* and *Completely sure it is true*) as misconceptions that are
312 accepted by participants. In the other hand, means around 1 and 2 [<2.5] (*Completely sure it is*
313 *false* and *I think it is false*) are considered as detected myths. Therefore, the total sample believed
314 in a total of 9 misconceptions (12.16%); the participants from face-to-face university in 10
315 (13.51%) and the students of online, in 13 (17.56%). Most of the responses revolved around the
316 central score, "I don't know" [2.5-3.5]: for 30 items (40.54%) in the total sample, for 22
317 (29.73%) in face-to-face and for 38 (51.36%) in online. On the other hand, in the total sample, a
318 total of 35 myths (47.3%) were recognized as such; with 42 (56.76%) at face-to-face, and 23
319 (31.08%) at online (see Table 1).

320 The range of total scores in the questionnaire goes from 74 (score 1 in all myths) to 370 (score 5
321 in all myths). The higher the score, the most belief in myths. For the total sample was obtained a
322 mean score of 194.82 points ($SD = 25.11$, $min. = 128$, $max. = 275$) (Figure 1). If the information
323 was analyzed according to the type of university, online presented a higher score ($M = 206.391$,
324 $SD = 22.15$, $min. = 138$, $max. = 275$), in relation to that obtained in face-to-face ($M = 177.274$,
325 $SD = 18.25$, $min. = 128$, $max. = 240$). Higher scores were found among first year students ($M =$

326 202.16; $SD = 24.84$) compared to those in the final year of the Degree ($M = 181.55$; $SD = 20.95$)
327 (see Table 3 in the supplemental materials to consult the means of the total score, according to
328 university and the academic year).

329 **Effects of type of university and academic year on belief in myths in Psychology.**

330 There was a statistically significant main effect of the type of university factor associated with a
331 large effect size, following Cohen's criteria (1988), $F(1,908) = 65.908$, $p < 0.01$, $\eta_G^2 = 0.216$.
332 This effect shows that face-to-face students believe to a lesser extent in this kind of myths, as the
333 mean total score of this university was lower ($M = 177.27$) than that found among the online
334 students ($M = 206.39$).

335 Although with small effect size, a statistically significant effect was found for the academic year
336 variable, which indicates that beliefs differ according to the year in which the participants are
337 enrolled $F(3,908) = 27.256$, $p < 0.01$, $\eta_G^2 = 0.083$. Multiple *post hoc* comparisons with the
338 Bonferroni correction indicated significant differences between the first and the rest of the
339 academic years ($p < 0.01$), as well as between the second and the first year and between the
340 second and the fourth year ($p < 0.01$) (see Figure 2).

341 There was a statistically significant effect of the interaction between these two variables. The
342 influence of the academic year on belief in myths was different for students from the two
343 universities participating in the sample, participants from the face-to-face university were less
344 prone than online one to believe in myths, while the latter benefited more from formal education.
345 Although the effect size found was small ($F(3,908) = 8.944$, $p < 0.01$, $\eta_G^2 = 0.029$) (Figure 2).

346 The summary of the ANOVA results can be found in Table 4 in the supplemental materials.

347 **Effect of familiarity with scientific dissemination**

348 A total of 23.62% ($n = 86$) of the face-to-face university participants claimed familiarity with
349 scientific dissemination. At the online, this figure rose to 27.17% ($n = 150$). In total, 236
350 participants (25.76%) reported performing this activity (see Table 5 in the supplemental
351 materials for a scientific dissemination sources classification).

352 The performance of a Student's *t*-test for independent samples with an associated statistic $t_{425,05} =$
353 3,301 ($p < 0.001$; $IC95\% = [2.470, 9.742]$) indicates that there was a statistically significant
354 effect of familiarity with scientific dissemination compared to non-familiarity with the belief in
355 myths of Psychology. This effect favors those who claim to do so, by obtaining a lower mean in
356 the total score (Figure 3 and Table 6 in the supplemental materials). However, the effect size
357 found was small (Cohen's $d = 0.244$).

358

Discussion

359 The present study aimed to analyze the prevalence of psychology-related myths in Psychology
360 students in Spain and the influence of three variables on this prevalence: the academic year they
361 are enrolled in, the university in which they study (associated with different characteristic student
362 profiles) and their familiarity with scientific dissemination. The data analyzed sustained that,
363 within the sample used, the variables of academic year, type of university and familiarity with
364 scientific dissemination had a statistically significant effect on the belief in myths in Psychology.
365 The chosen sample size favored the external validity of the study and the generalization of its
366 results to similar populations. According to the data we obtained, it could be concluded that
367 students were capable of recognizing most of the myths that appeared in the questionnaire as
368 such, while they still lacked certain limited knowledge regarding certain aspects of the discipline.
369 Thereby, belief in misconceptions regarding Psychology in the chosen sample cannot be

370 considered high, compared to the values indicated in Hughes, Lyddy and Lambe's review (2013)
371 or compared to the original study by Gardner and Brown (2013).

372 The effects found concerning to the academic year within the Degree in Psychology and the
373 familiarity with scientific dissemination were statistically significant. However, the reported
374 effect sizes were small. This refers to a limitation of the benefits of the different educational
375 tools (formal, as is the case of the degree; informal, in the case of scientific dissemination),
376 which is consistent with the previous literature (e.g., see Furnham & Hughes, 2014; Hughes,
377 Lyddy & Lambe, 2013). Likewise, the trend that was already reflected in the scientific literature
378 was noted - that as the academic year progressed, the proportion of myths decreased (e.g.,
379 Gardner & Dalsing, 1986).

380 The effect of the type of university was also statistically significant, with an associated effect
381 size larger than that of the other two factors. Similarly, the academic year had a differential effect
382 on the belief in these myths depending on the university where the psychology studies were
383 carried out. Thus, the reduction in the prevalence of myths that was perceived through the
384 academic year was more prominent at online university. Perhaps it is because these students
385 started from a much higher level of misconceptions. This may be due to the different
386 demographic characteristics that separate these students into different groups as, for example,
387 age. While the face-to-face university, UAM, sample was composed of young people studying
388 their first university degree, the online, UNED, sample showed a mean age difference of one
389 decade. Also, participants from online use to have qualitatively higher familiar and working
390 responsibilities compared to face-to-face participants. City or country of residence could also
391 affect to these results, whereas face-to-face students are living in Madrid or near cities, the online
392 ones are spread all over the world. However, we are aware that our data by themselves cannot

393 explain these differences and more research must be conducted to study them and to find out
394 their causes.

395 Previous studies suggest that, in general, the higher the level of studies, the less belief in myths
396 (Furnham & Hughes, 2014; Gardner & Dalsing, 1986). With these data, it could be postulated
397 that online students should believe less in myths. However, these studies have been carried out in
398 comparison with the general population, and not within the Psychology student body itself.
399 Having accumulated prior knowledge of different areas or the priority that the studies they are
400 studying have in their day to day can be examples of other variables that are influencing the
401 belief of myths, ensuring a higher score on this type of scales.

402 It is necessary to emphasize that the effect of formal education that we found is quite limited.
403 Possible explanations for this phenomenon would lie in the analysis of what happens in the
404 classroom. The refutational techniques on popularized ideas about Psychology have proven to be
405 effective in this case; however, they are underused or absent (Bensley & Lilienfeld, 2015;
406 Gardner & Dalsing, 1986). The illustration that is made in some subjects of Psychology as a set
407 of isolated plots of knowledge, without any relation to each other, can also be counterproductive.
408 This is consistent with what some studies pointed out: after discussing misconceptions in class,
409 belief in them decreases, but re-emerges when moving to a different topic (Lyddy & Hughes,
410 2012). It is the so-called *rebound effect* (Lewandowsky et al., 2012). That is, the explanations
411 that are given do not acquire the degree of generalization necessary for them to produce stable
412 modifications over time in the beliefs of the students. In addition, it is possible that belief in
413 myths could be enhanced within the universities. Some authors indicate that problems when
414 teaching introductory courses on the philosophy of science that supports Psychology can
415 influence the subsequent development of misconceptions in this regard (García García et al.,

416 2006). By not knowing the scope, implications, and characteristics of this discipline, it is difficult
417 to distinguish between what is valid and what is not.

418 In this study, familiarity with scientific dissemination proved to have a positive but limited
419 effect. Only a small proportion of the sample claimed to carry out such activity and it was more
420 frequent among the online participants. Two characteristics shared by some sources of
421 dissemination considered is that they are accessible and practical, which favors their propensity.
422 The journals that have the title "Psychology" and other complementary words, widely
423 disseminated without their recognition being due to the scientific quality of their contents, may
424 present partial truths or biased statements that, although well directed, are not completely correct.
425 As they are not reviewed by accredited specialists in the field, there is no possible filter. Part of
426 the reduced effect size found could be explained by this. As reported in Lewandowsky et al.
427 (2012), the fact that now people stopped having a passive role and have begun to create content
428 in the media (often online) can spread misinformation, rather than having an exclusively positive
429 side. Also, social media allow the possibility of creating a community between users with the
430 same interests is added. While the debates that take place online can be enriching, the effect that
431 can be obtained is the opposite when handling information that is not verified. Some studies have
432 already explored the possible advantages of using social networks such as Twitter in the
433 academic world (e.g., see Letierce et al., 2010). Students must be provided with the appropriate
434 tools that will allow them to make the most of these information options.

435 The present study has also some limitations to consider. Firstly, the item presentation order was
436 predefined by experimenters and the same for all participants. This could cause some undesirable
437 effects such as fatigue or practice effects, that affect to participants' responses. Future studies
438 may consider to randomize or counterbalance the order of item presentation to avoid these

439 effects and their influence on the measure of the believe in myths. Also, future studies could
440 measure, not only the belief in myths, but also the participants' knowledge of true ideas about
441 human behavior. That will allow researchers to compare these two approaches and explore if
442 there is a relation between them.

443 Another limitation of our study is related with the measure of the scientific dissemination
444 variable, what could negatively affect our results and make them less precises. While the
445 university and the academic year are easy to answer questions, measuring the familiarity with
446 scientific dissemination is less so. For example, participants may don't know what scientific
447 dissemination is or have an incorrect idea of it. Also, participants could be not able to distinguish
448 scientific vs pseudo-scientific dissemination, which not only will decrease the belief in myths but
449 could it makes increase. Finally, we did not distinguish how much participants are familiar with
450 scientific dissemination. Although our results pointed out that those participants that reported
451 scientific dissemination believing less in myths than those that do not in both universities, to
452 assess this factor more precisely and to delve deeper into how these two variables -being familiar
453 with scientific dissemination and how much so- are related, probably using more than one
454 question to do so, to obtain a more sensible measure.

455 As far we know, the authors of the original test we used did not analyze its construct and
456 convergent validity, neither we do. In order to provide more reliable information, this could be
457 analyzed and reported. Finally, it is recommendable to estimate the sample size needed to
458 achieve adequate statistical power. Here we did not estimate it, but we tried to obtain the most
459 participants as possible. Future research could calculate the minimun necessary sample size
460 following the recommendations for this kind of research (e.g., Hair et al. 2010).

461

462

Conclusions

463 The results of the present study offer a sample of the belief in myths in Psychology among
464 students of this discipline in Spain. Thus, there is no clear defense of myths as true statements by
465 psychology students, although a large number of responses were found to be around the mean
466 value of the scale ("*I don't know*"). The main conclusions of the study could be summarized in
467 these three: a) Students enrolled in higher academic years tend to believe less in myths than those
468 who coursing initial years; b) Familiarity with scientific dissemination is paired to a decrement in
469 the belief in myths, although its benefits seem restricted in scope; c) Prevalence of belief in
470 myths varies according to the characteristics of the universities of origin, in such a way that
471 students enrolled in a online university belief more than those who belong to a face-to-face one.
472 Another interesting finding is that participants of online university experience a greater reduction
473 in belief in this type of misconceptions through year, but they do not reach the level from which
474 students enrolled in face-to-face universities start.

475 It is known that accepting myths in psychology as true correlates with accepting other
476 misconceptions in other fields, such as the belief in paranormal events or in pseudoscientific
477 practices as true practices (Bensley, Lilienfeld & Powell, 2014). Given that this type of study is
478 beginning to be carried out in Spain, future lines of research should explore other possible
479 variables, beyond those analyzed in this study, for their connection with the belief in these types
480 of ideas. Identifying the myths currently held by students is the first step in establishing effective
481 interventions. Treating these misconceptions early is necessary to train professionals who, on the
482 applied side, provide the most effective services for their users and that, on the theoretical side,
483 do not compromise the advancement of behavioral science with these obstacles.

484

485 **Acknowledgements**

486

487 Special thanks to Miguel A. Vadillo and Marta Ferrero for their participation in the research
488 design, the adaptation of the questionnaire used, and for making the work so enjoyable.

694 Figure 1. Histogram of the total score obtained in the questionnaire.

695 Figure 2. Effect of the interaction between university and academic year on the total score of the
696 questionnaire.

697 Figure 3. Effect of the familiarity with scientific dissemination on the total score (by type of
698 university).

Figure 1

Figure 1. Histogram of the total score obtained in the questionnaire.

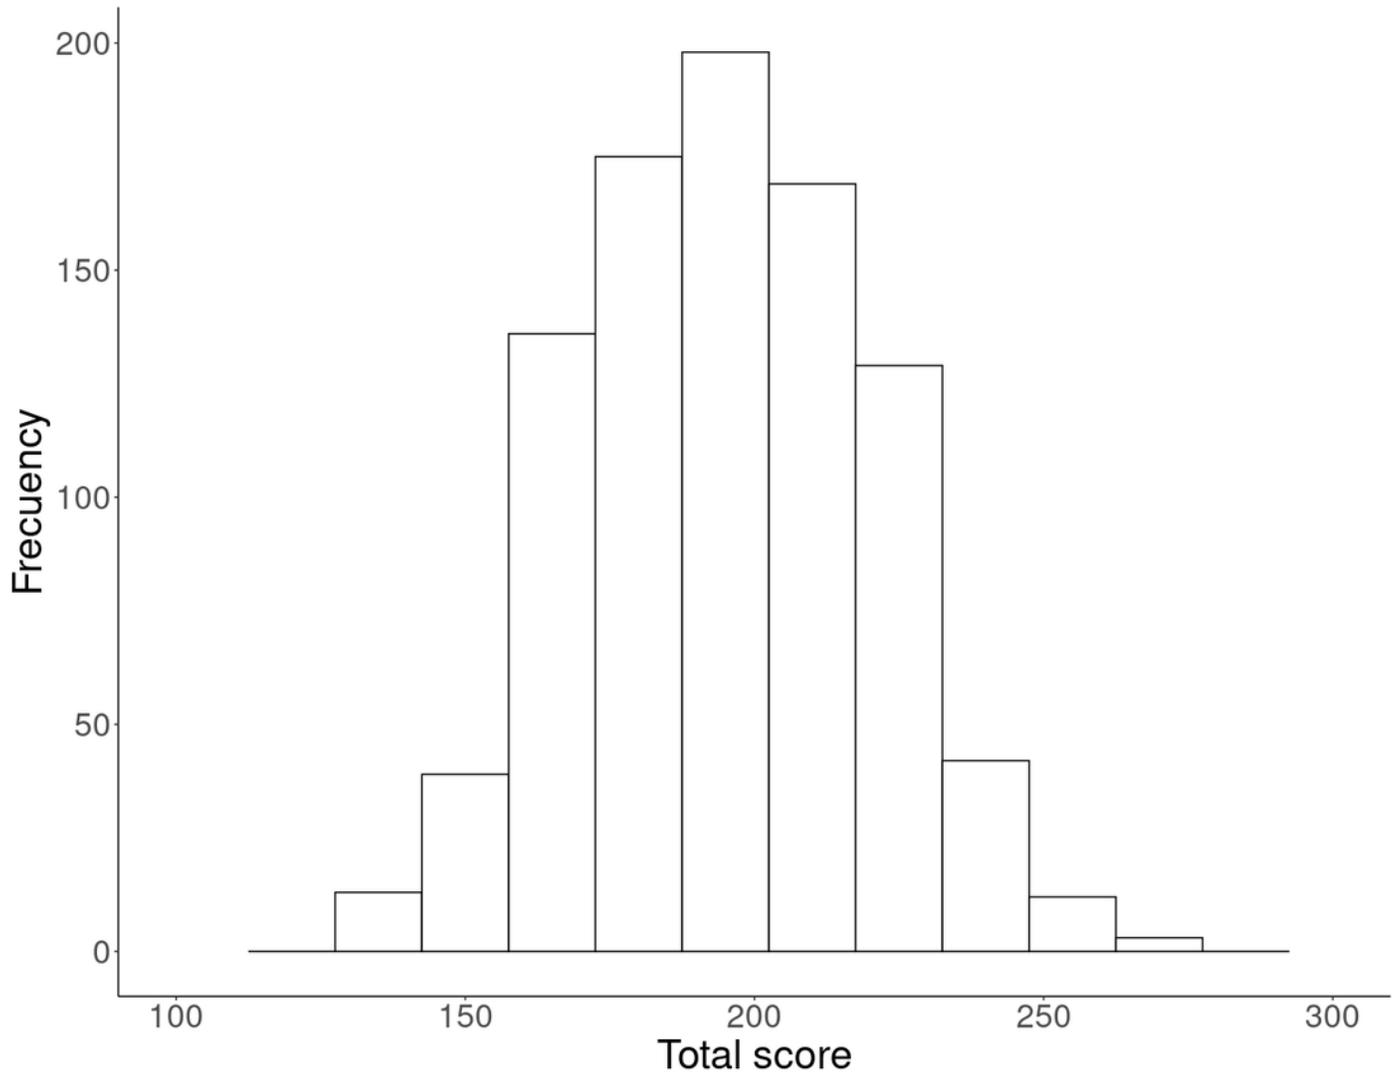

Figure 2

Figure 2

Effect of the interaction between university and academic year on the total score of the questionnaire.

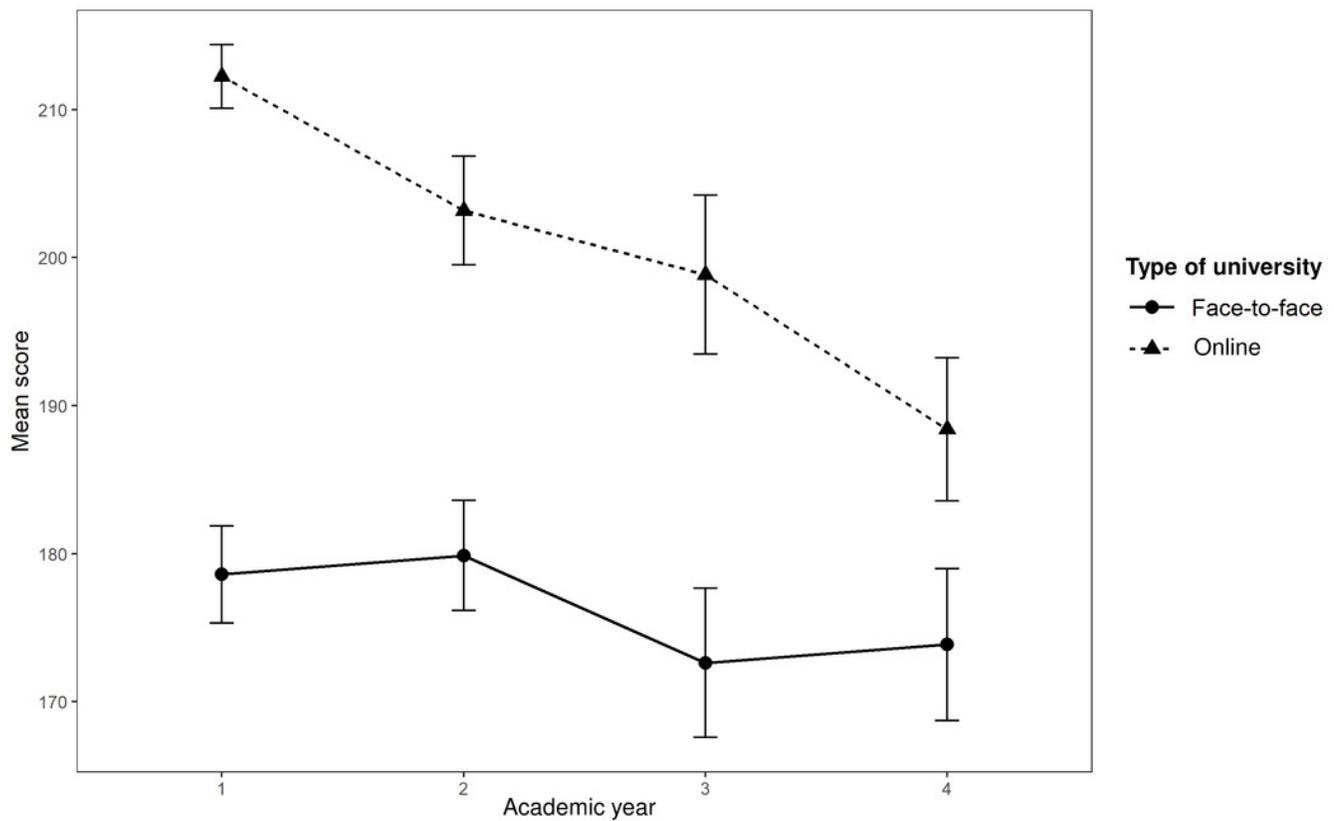

Figure 3

Effect of the familiarity with scientific dissemination on the total score (by university).

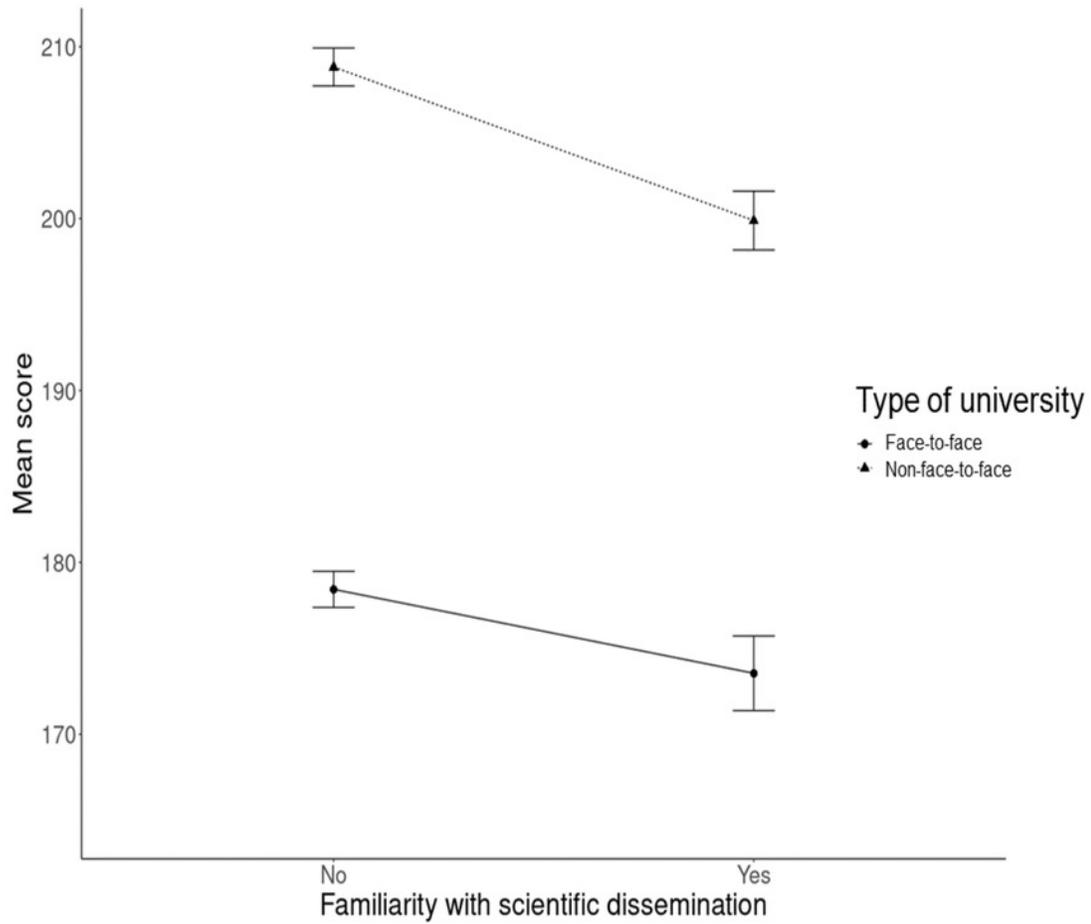

Table 1 (on next page)

Table 1

Means and standard deviations (in parentheses) of the questionnaire items as a function of the total and separated by university. Ordered from highest to lowest by the score obtained in the total sample. Inverse test items are included, recoded, so that a higher mean indicates greater belief in the misconception.

1 Table 1.
 2 Means and standard deviations (in parentheses) of the questionnaire items as a function of the total and separated by
 3 university. Ordered from highest to lowest by the score obtained in the total sample. Inverse test items are included,
 4 recoded, so that a higher mean indicates greater belief in the misconception.

ITEM	Total	Face- to-face	Online
	Mean (SD)	Mean (SD)	Mean (SD)
13. Individuals commonly DON'T repress the memories of traumatic experiences. (*)	4.27 (1.04)	4.03 (1.14)	4.44 (0.94)
25. Students learn best when teaching styles are matched to their learning styles.	4.22 (0.9)	4.10 (0.88)	4.30 (0.90)
12. When dying, people DON'T pass through a universal series of psychological stages. (*)	4.12 (1.07)	3.83 (1.13)	4.32 (0.98)
5. Subliminal messages can't persuade people to perform some behaviors. (*)	4.1 (1.2)	3.95 (1.23)	4.29 (1.16)
17. Some people have true photographic memories.	4.07 (1.02)	3.75 (1.12)	4.29 (0.89)
58. Most people who experience severe trauma, (e.g., as in military combat) DON'T develop posttraumatic stress disorder (PTSD). (*)	3.96 (1.07)	3.80 (1.11)	4.07 (1.04)
68. More experienced therapists are generally NO more effective than those with little experience. (*)	3.77 (1.09)	3.76 (1.06)	3.77 (1.11)
28. Hypnotized people are aware of their surroundings and can recall the details of conversations overheard during hypnosis. (*)	3.7 (1.12)	3.32 <i>(1.15)</i>	2.90 <i>(1.07)</i>
72. Electroconvulsive therapy is rarely administered today.	3.67 (1.10)	3.7 (1.09)	3.66 (1.12)
26. Direct instruction is superior to discovery learning. (*)	3.49 <i>(1.2)</i>	3.41 <i>(1.14)</i>	3.54 (1.24)
46. People's attitudes are NOT highly predictive of their behaviors. (*)	3.48 <i>(1.21)</i>	3.25 <i>(1.26)</i>	3.62 (1.16)
21. There is a modest correlation between brain size and IQ in humans. (*)	3.44 <i>(1.24)</i>	3.55 (1.31)	3.36 <i>(1.18)</i>
67. Crowding consistently leads to more aggression.	3.43 <i>(1.08)</i>	3.61 (1.03)	3.30 <i>(1.10)</i>
38. Positive thinking is better than negative thinking for all people.	3.38	2.95	3.67

	<i>(1.31)</i>	<i>(1.28)</i>	(1.25)
15. The memory of everything we've experienced is stored permanently in our brains, even if we can't access all of it.	3.36 <i>(1.39)</i>	2.91 <i>(1.42)</i>	3.66 (1.30)
64. Most people that plead insanity are NOT faking mental illness. (*)	3.32 <i>(1.04)</i>	3.08 <i>(0.95)</i>	3.47 <i>(1.07)</i>
33. Awakening a sleepwalker is NOT dangerous. (*)	3.29 <i>(1.4)</i>	3.16 <i>(1.42)</i>	3.37 <i>(1.36)</i>
7. People become increasingly satisfied with their lives in old age. (*)	3.20 <i>(1.09)</i>	3.22 <i>(1.08)</i>	3.18 <i>(1.10)</i>
50. Most children survive the divorce of their parents without much, if any, long-term psychological damage. (*)	3.20 <i>(1.22)</i>	2.88 <i>(1.23)</i>	3.42 <i>(1.17)</i>
35. Ulcers are caused primarily by stress.	3.15 <i>(1.1)</i>	3.08 <i>(1.04)</i>	3.20 <i>(1.13)</i>
39. Voice stress analyzers can help to detect lying.	3.13 <i>(1.23)</i>	2.53 <i>(1.21)</i>	3.52 <i>(1.08)</i>
23. Irregularly provided feedback best promotes long-term learning. (*)	2.98 <i>(1.25)</i>	3.02 <i>(1.27)</i>	2.95 <i>(1.25)</i>
60. Hallucinations are almost always a sign of serious mental illness.	2.93 <i>(1.29)</i>	2.54 <i>(1.20)</i>	3.19 <i>(1.28)</i>
31. Our brains rest during sleep.	2.91 <i>(1.5)</i>	2.57 <i>(1.41)</i>	3.13 <i>(1.52)</i>
36. Women are NO better than men at accurately guessing the feelings of others. (*)	2.91 <i>(1.34)</i>	2.4 <i>(1.28)</i>	3.26 <i>(1.28)</i>
4. Extrasensory perception is NOT a real phenomenon. (*)	2.88 <i>(1.42)</i>	2.38 <i>(1.43)</i>	3.22 <i>(1.32)</i>
44. The best way to change someone's attitude is to give them a large reward to do so.	2.83 <i>(1.31)</i>	3.08 <i>(1.34)</i>	2.66 <i>(1.27)</i>
42. Expressing anger directly toward another person or object makes us more aggressive. (*)	2.81 <i>(1.17)</i>	3.03 <i>(1.07)</i>	2.67 <i>(1.20)</i>
8. Most adopted children are psychologically healthy.	2.8 <i>(0.99)</i>	2.99 <i>(1.02)</i>	2.71 <i>(0.96)</i>
49. Most people who were physically abused as children DON'T go on to become abusers themselves. (*)	2.8 <i>(1.21)</i>	2.53 <i>(1.22)</i>	2.98 <i>(1.18)</i>
57. All clinically depressed people suffer from extreme sadness.	2.78 <i>(1.32)</i>	2.62 <i>(1.30)</i>	2.89 <i>(1.33)</i>
20. IQ scores are relatively unstable during childhood. (*)	2.77	3.04	2.59

	(1.08)	(1.10)	(1.03)
61. Homicide is more common than suicide.	2.73 (1.24)	2.72 (1.22)	2.74 (1.26)
22. As a general rule, students typically recall only 10% of what they read.	2.71 (1.1)	2.35 (1.04)	2.95 (1.07)
71. Taking a placebo (i.e. sugar pill) can change brain functioning and its chemistry. (*)	2.68 (1.38)	2.66 (1.39)	2.70 (1.37)
24. Negative reinforcement is a type of punishment.	2.65 (1.61)	1.88 (1.37)	3.16 (1.55)
55. People with schizophrenia DON'T have multiple personalities. (*)	2.65 (1.3)	2.31 (1.23)	2.88 (1.30)
11. Playing classic music to infants DON'T boosts their intelligence. (*)	2.63 (1.4)	1.82 (1.19)	3.16 (1.27)
29. It is impossible to lie under hypnosis.	2.52 (1.01)	2.34 (1.03)	2.64 (0.98)
27. Hearing material while we are asleep (sleep learning) can be an effective aid to learning.	2.42 (1.25)	1.8 (1.07)	2.84 (1.20)
63. The words "insanity" and "sanity" are purely legal NOT psychological terms. (*)	2.4 (1.16)	2.23 (1.08)	2.52 (1.19)
73. Expert judgment and intuition are the best means of making clinical decisions.	2.39 (1.22)	2.11 (1.16)	2.58 (1.24)
37. Unfamiliarity breeds contempt: We dislike things we have less exposure to. (*)	2.37 (1.12)	2.19 (1.09)	2.50 (1.13)
45. Men and women communicate in completely different ways.	2.3 (1.18)	1.81 (0.98)	2.61 (1.19)
53. People's responses to inkblots tell us a great deal about their personalities.	2.29 (1.29)	1.52 (0.97)	2.80 (1.22)
43. Groups tend to make less extreme decisions than individuals.	2.28 (1.4)	1.94 (1.23)	2.52 (1.45)
9. Married couples enjoy more marital satisfaction after they have children.	2.23 (0.94)	2.29 (0.95)	2.18 (0.94)
18. Human memory works like a tape recorder, and accurate records events we've experienced.	2.16 (1.23)	1.54 (0.94)	2.57 (1.33)
40. We are most romantically attracted to people who are similar to us. (*)	2.15 (1.15)	1.93 (1.11)	2.30 (1.15)
74. Most modern therapies are NOT based on the teachings of Freud. (*)	2.14	1.92	2.29

	(1.14)	(1.06)	(1.17)
59. Psychiatric hospital admissions and crimes DON'T increase during full moons. (*)	2.12 (1.39)	1.46 (1.07)	2.56 (1.41)
56. There has recently been a massive epidemic of childhood autism.	2.08 (1.10)	2.03 (1.09)	2.11 (1.12)
1. Most people use only about 10% of their brain power.	2.07 (1.38)	1.24 (0.76)	2.62 (1.43)
6. Humans have an invisible body energy that can cause psychological problems when blocked.	2.04 (1.25)	1.44 (0.75)	2.44 (1.36)
62. Most rapes are committed by strangers.	1.99 (1.02)	1.96 (1.04)	2.02 (1.02)
19. Rote memorization is NOT the best way to retain information. (*)	1.97 (1.13)	1.86 (1.05)	2.05 (1.18)
34. The polygraph (lie detector) test is NOT an accurate means of detecting dishonesty. (*)	1.96 (1.16)	1.36 (0.81)	2.35 (1.19)
66. Rehabilitation programs have NO effect on the recidivism rates of criminals.	1.96 (0.96)	1.87 (0.87)	2.02 (1.02)
41. The more people present at an emergency, the greater the chance that someone will intervene.	1.95 (1.34)	1.84 (1.35)	2.03 (1.32)
14. People with amnesia can still recall some details of their earlier lives. (*)	1.88 (0.97)	1.78 (0.93)	1.95 (1.00)
16. With effort, we can remember events back to the time of our birth.	1.86 (1.05)	1.46 (0.72)	2.13 (1.16)
2. Almost all color-blind people can see at least some colors. (*)	1.84 (1.06)	1.85 (1.026)	1.84 (1.08)
47. We CANNOT tell a person's personality by merely looking at their handwriting. (*)	1.84 (1.19)	1.23 (0.72)	2.24 (1.26)
52. The fact that a trait is heritable means we CAN'T change it.	1.83 (1.1)	1.64 (1.02)	1.96 (1.14)
69. Most psychotherapy involves a couch and exploring one's early past.	1.8 (1.15)	1.66 (1.11)	1.89 (1.17)
51. Obese people are more cheerful ("jolly") than thin people.	1.71 (0.92)	1.6 (0.82)	1.87 (0.96)
65. Most psychopaths are violent.	1.68 (0.88)	1.52 (0.77)	1.80 (0.93)
3. Some people are exclusively left-brained while others are right-	1.67	1.27	1.94

brained.	(1.01)	(0.55)	(1.16)
54. Only deeply depressed people commit suicide.	1.64 (0.97)	1.47 (0.9)	1.75 (1.00)
70. Antidepressants are much more effective than psychotherapy for treating depression.	1.63 (0.85)	1.54 (0.81)	1.70 (0.87)
30. Virtually all people dream. (*)	1.6 (0.96)	1.64 (0.93)	1.58 (0.98)
10. Infants establish attachment bonds only to their mothers.	1.45 (0.87)	1.12 (0.44)	1.66 (1.01)
48. Knowing a person's astrological sign predicts their personality traits at better than chance levels.	1.42 (0.84)	1.18 (0.61)	1.59 (0.94)
32. Researchers have demonstrated that dreams possess symbolic meaning.	1.36 (1.3)	1.77 (1.09)	2.75 (1.29)

5
