Background Diabetic kidney disease (DKD) is the leading cause of death in people with type 2 diabetes mellitus (T2DM). The main objective of this study is to find the potential biomarkers for diabetic kidney disease. **Materials and Methods** Two datasets (GSE86300 and GSE184836) retrieved from GEO database were used, combined with our RNA sequencing (RNA-seq) results of DKD mice (C57 BLKS-26W db/db) and nondiabetic (db/m) mice for further analysis. After processing the expression matrix of the 3 sets of data using R software "Limma", differential expression analysis was performed. The significantly differentially expressed genes (DEGs) ($|\log FC| > 1$, $p\text{-value} < 0.05$) were visualized by heatmaps and volcano plots respectively. Next, the co-expression genes expressed in the 3 groups of DEGs were obtained by constructing a Venn diagram. In addition, Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis were further analyzed the related functions and enrichment pathways of these co-expression genes. Then, qRT-PCR was used to verify the expression levels of co-expression genes in the kidney of DKD and control mice. Finally, protein-protein interaction network (PPI), GO, KEGG analysis and Pearson correlation test were performed on the experimentally validated genes, in order to clarify the possible mechanism of them in DKD disease. **Results** Our RNA-seq results identified a total of 124 DEGs, including 58 up-regulated and 66 down-regulated DEGs. At the same time, 181 up-regulated and 151 down-regulated DEGs were obtained in GEO database GSE86300, and 107 up-regulated and 208 down-regulated DEGs were obtained in GSE184836. Venn diagram showed that 10 co-expression DEGs among the 3 groups of DEGs. GO analysis showed that BP was mainly enriched in steroid metabolism, lipid localization, cellular ketone metabolism, fatty acid metabolism, organic hydroxy compounds, response to fatty acid, and lipid transport. KEGG pathway analysis showed that the 3 major enriched pathways were cholesterol

metabolism, steroid hormone biosynthesis, and bile secretion. After qRT-PCR validation, we obtained 8 genes that were significant differentially expressed in the kidney tissues of DKD mice compared with control mice. (The mRNA expression levels of Ugt8a, Apoh, Akr1c14, Lpl, Slc1a4, and Cd36 were declined, whereas Abcc4 and Ltc4s were elevated.)

Conclusion Our study, based on RNA-seq results, GEO databases and qRT-PCR, identified 8 significant dysregulated DEGs, which play an important role in lipid metabolism and provide novel targets for diagnosis and treatment of DKD.

Abstract

Background Diabetic kidney disease (DKD) is the leading cause of death in people with type 2 diabetes mellitus (T2DM). The main objective of this study is to find the potential biomarkers for diabetic kidney disease.

Materials and Methods Two datasets (GSE86300 and GSE184836) retrieved from GEO database were used, combined with our RNA sequencing (RNA-seq) results of DKD mice (C57 BLKS-26W db/db) and nondiabetic (db/m) mice for further analysis. After processing the expression matrix of the 3 sets of data using R software "Limma", differential expression analysis was performed. The significantly differentially expressed genes (DEGs) ($|\log FC| > 1$, p -value < 0.05) were visualized by heatmaps and volcano plots respectively. Next, the co-expression genes expressed in the 3 groups of DEGs were obtained by constructing a Venn diagram. In addition, Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis were further analyzed the related functions and enrichment pathways of these co-expression genes. Then, qRT-PCR was used to verify the expression levels of co-expression genes in the kidney of DKD and control mice. Finally, protein-protein interaction network (PPI), GO, KEGG analysis and Pearson correlation test were performed on the experimentally validated genes, in order to clarify the possible mechanism of them in DKD disease.

Results Our RNA-seq results identified a total of 124 DEGs, including 58 up-regulated and 66 down-regulated DEGs. At the same time, 181 up-regulated and 151 down-regulated DEGs were obtained in GEO database GSE86300, and 107 up-regulated and 208 down-regulated DEGs were obtained in GSE184836. Venn diagram showed that 10 co-expression DEGs among the 3 groups of DEGs. GO analysis showed that BP was mainly enriched in steroid metabolism, lipid localization, cellular ketone metabolism, fatty acid metabolism, organic hydroxy compounds, response to fatty acid, and lipid transport. KEGG pathway analysis showed that the 3 major enriched pathways were cholesterol metabolism, steroid hormone biosynthesis, and bile secretion. After qRT-PCR validation, we obtained 8 genes that were significant differentially expressed in the kidney tissues of DKD mice compared with control mice. (The mRNA expression levels of Ugt8a, Apoh, Akr1c14, Lpl, Slc1a4, and Cd36 were declined, whereas Abcc4 and Ltc4s were elevated.)

Conclusion Our study, based on RNA-seq results, GEO databases and qRT-PCR, identified 8 significant dysregulated DEGs, which play an important role in lipid metabolism and provide novel targets for diagnosis and treatment of DKD.

Key words: DKD; RNA-seq; bioinformatics analysis; differentially expressed genes (DEGs); biomarkers.

1.Introduction

Diabetic mellitus (DM) is a chronic metabolic disease that seriously affects public health. According to the World Health Organization (WHO), about 629 million people will suffer from T2DM by 2045, and the complications may affect various organs throughout the body and have a high mortality and disability rate [1]. Diabetic kidney disease (DKD) is a common chronic complication of DM, which has gradually overtaken glomerulonephritis and hypertension and is the leading cause of death in patients with DM and end-stage renal disease (ESRD) [2]. The main features of progression of DKD are hypertension, increased protein in urine, and decreased estimated glomerular filtration rate (eGFR). Early pathological changes mainly include thickening of the glomerular and tubular basement membrane, which gradually develops into glomerular extracellular matrix (ECM) accumulation and tubular interstitial fibrosis as the disease progresses, eventually causing irreversible

damage to the renal structure. Most experts believe that the pathogenesis of DKD is mainly due to the interaction of renin-angiotensin-aldosterone system (RAAS), advanced glycation end products (AGEs), transforming growth factor- β 1 (TGF- β 1), protein kinase C (PKC), mitogen-activated protein kinases (MAPKs) and reactive oxygen species (ROS), which affect renal function through inflammation and oxidative stress. [3] Although various treatments have been used to improve metabolism, hemodynamic disturbances, and fibrosis, the mortality rate of patients with DKD remains high. Therefore, the key to improving the quality of life and survival rate is to find biomarkers for early diagnosis of DKD and to develop new strategies and prevention of deterioration of renal function.

In recent years, many biomarker molecules have been found to be associated with changes in renal structure and function in DKD patients, such as urine markers, serum/plasma markers, etc [4]. However, it can only be used for the current diagnosis of DKD, fails to diagnose at early stage. With the development of the new generation of high-throughput sequencing technology and bioinformatics techniques, the ability of humans to understand diseases from the root has greatly improved, and more and more disease-related risk genes have been discovered. This promises revolutionary advances in disease diagnosis and treatment in the future [5]. Many microarray-based studies have shown that some small molecules such as non-coding RNAs and mRNAs play important roles in the pathogenesis of DKD. They influence disease occurrence, progression, and prognosis through their interactions and regulation of signaling pathways. For example, studies have shown that leucine rich- α -2 glycoprotein 1 (LRG1) expression is increased in kidneys of diabetic patients and mice, it can be used as a biomarker for early diagnosis of DKD [6]. The expression of SH3YL1 in the serum of DKD patients, in kidney tissues of db/db mice, and in podocytes, is higher than control group, so it also has the potential as a biomarker for the early diagnosis of DKD [7]. By combining clinicopathological data with mRNA analysis of urine from DKD patients, it was found that LYZ, C3, FKBP5, and G6PC are associated with renal tubulointerstitial inflammation and fibrosis, and their expression levels reflect the renal pathological types of DKD patients, and that they can also predict the prognosis of renal function [8]. Some researchers also used bioinformatics methods to analyze multiple datasets in the GEO database and proved that the increased expression of AEBP1 in plasma exosomes of DKD patients may also be a novel biomarker [9].

The pathogenesis of DKD is complex, which is related to oxidative stress, inflammation, autophagy, apoptosis, and other mechanisms. However, its pathogenesis still needs further study. Although many mRNAs are currently thought to play a role in DKD, there are few consistent results across studies. We need to obtain more data by biotechnological methods and increase the number of experiments so that the results of the different genes have higher authenticity and reliability.

Our analysis was conducted following the procedure presented in Fig 1. Kidney tissues from DKD and control mice were isolated and RNA was extracted for RNA-seq, and DEGs were determined. To reduce the false-positive rate of experimental results, the GSE86300 and GSE184836 RNA-seq datasets of kidneys from DKD mice were extracted from the GEO (Gene Expression Omnibus) database. Finally, 10 co-expression genes were determined by the combined analysis of the 3 datasets, qRT-PCR verified that 8 of them had the same expression trend as the above sequencing results.

2. Materials and Methods

2.1 Data source

2.1.1 Transcriptome sequencing of kidney tissues from DKD and Control mice

1) Animal model

Six C57 BLKS-db/db mice and six db/m mice (6-week-old, male) were selected as the model group (body weight 34.35 ± 2.52 g), normal control group (body weight 18.94 ± 1.44 g) respectively. They were purchased from Nanjing Institute of Model Zoology and reared in the barrier system of Animal Experimental Research Centre of Lanzhou University Second Hospital. The feeding temperature is (20 ± 2) °C, the humidity is 40%-70%, the light alternates between light and dark every 12 hours, the ordinary Specific Pathogen Free (SPF) food is fed and the drinking water is free. After these mice were fed for 20 weeks, the mice were euthanized by intraperitoneal injection of 10% chloral hydrate and the kidney tissues were collected. 50 mg of the right kidney was divided into cryogenic vials, frozen with liquid nitrogen and stored in the refrigerator at -80°C. All the experiments involving animals were performed after Lanzhou University Second Hospital Institutional Ethical Committee's approval and under the strict adherence to the National Institutes of Health Guide for laboratory animals' care and use, our ethical review acceptance number is D2019-198.

2) RNA extraction from kidney tissues

Approximately 50 mg of each kidney tissue sample was placed in grinding tubes, and 1 ml of Trizol was added to each tube and ground completely. Then the samples were allowed to stand for 5 minutes at room temperature, and 0.2 ml of chloroform was added to each tube and shaken vigorously for 15 seconds. After the samples stand at room temperature for 3 minutes, the supernatant was centrifuged at high speed (12000 rpm, 4°C) for 15 minutes and transferred to a Rnase-free centrifuge tube. Next, add 0.5 mL isopropyl alcohol, mix gently and let stand at room temperature for 10 minutes, centrifuge for 10 minutes (12000 rpm, 4°C), wash the precipitate with 1 mL 75% ethanol, centrifuge for 5 minutes (7500 rpm, 4°C), remove the liquid, dry at room temperature for 10 minutes. 150uL diethyl pyrocarbonate (DEPC) H₂O was added and gently mix. At last, the precipitate was left at 55°C for 10 minutes to dissolve and stored temporarily at -80°C for further sequencing.

3) RNA-sequencing (RNA-seq)

In this study, we need to consider and deal with the difference expression caused by the biological variability, by far the most commonly used and most effective way is to set up biological replicates, biological replicates can not only test the relevance of the biology of repeatability, it can also assess the reliability of differentially expressed genes and assist in screening abnormal samples. Pearson's correlation coefficient was taken as the evaluation index of biological repetition correlation (the closer it is to 1, the stronger the correlation between two repeated samples is) (Supplementary fig.1). All biological repeat samples under the same conditions were extracted and built with the same person and batch, sequenced with same Run and Lane, and conducted a detailed analysis of the abnormal samples. Meanwhile, we set the Power value as 0.9, α value as 0.05 and then used the R language RNAseqPower package to calculate the sample size was 2.44, which could achieve 1.5 times of change, proving that the number of mice in each group selected as 3 is validate in our experiment.

Illumina's high-throughput sequencing platform was used to perform transcriptome sequencing on kidney tissue samples from DKD mice and Control mice. Clean data were obtained by filtering data from the Illumina high-throughput sequencing platform sequenced with the indicated reference genome. Subsequently, insertion fragment length test, random test, library quality assessment, alternative splicing analysis, novel gene discovery and gene structure optimization were performed. Finally, the number of mapped reads and transcript length were normalized in the sample. Fragments Per Kilobase Million (FPKM) was used as an indicator to measure gene expression levels. The expression matrix of FPKM can be obtained.

2.1.2 GEO database

GEO database was built by the National Center for Biotechnology Information (NCBI) and is a gene expression

database and online genome resource that collects high-throughput gene expression data uploaded from research institutes around the world. Diabetic nephropathy or diabetic kidney disease was entered as search objects. Gene expression microarray datasets GSE86300 and GSE184836 were selected and downloaded. The criteria for selecting the datasets were as follows: DKD and Control mice models with detailed gene expression information. The GSE86300 dataset, based on the GPL7546 platform, includes 10 DKD kidney tissue samples and 10 Control kidney tissue samples. The GSE184836 dataset, based on the GPL21103 platform, includes 6 DKD kidney tissue samples and 6 Control kidney tissue samples. The detailed information on these microarray datasets is listed in Supplemental Table 1.

2.2 Data processing methods

2.2.1 Differential expression analysis

All differential analyses of the 3 datasets were performed using the Limma packages in R/Bioconductor software. Genes in DKD renal tissue were up- or down-regulated compared with control groups, p -value less than 0.05 and $|\log_2 \text{fold change (FC)}|$ greater than 1 were considered statistically significant in differential analysis of the 3 datasets, $\log_2 \text{FC} > 1$ was regarded as up-regulated genes and $\log_2 \text{FC} < -1$ was down-regulated.

2.2.2 Volcano plots and heatmaps

Significant DEGs ($|\log_2 \text{FC}| > 1$, p -value < 0.05) were visualized using heatmaps and volcano curves. Both visualizations are completed on the "Weishengxin" website (<http://www.bioinformatics.com.cn/>).

2.2.3 Venn diagram

Determine the common genes of 3 datasets by creating a Venn diagram. The Venn diagram is completed on the "Weishengxin" website.

2.2.4 Functional enrichment analysis.

Gene Ontology (GO) annotation and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis were performed for DEGs. GO Annotation included analysis of biological processes (BP), cell components (CC), and molecular functions (MF). KEGG is an online database for pathway analysis of a large amount of genetic information. GO functional annotation analysis and KEGG pathway enrichment analysis were performed in the website "Weishengxin". The significant enrichment threshold was set as p -value < 0.05 , ten functions and pathways with the lowest p -values were selected as the top 10.

2.2.5 Quantitative real-time polymerase chain reaction (qRT-PCR)

Total RNA was extracted from fresh mice kidneys of DKD and control groups using the TRIZOL method. Total RNA (1 ug) was transcribed into cDNA using the GoScript™ Reverse Transcription System according to the manufacturer's protocol (Promega). qRT-PCR was performed on the ABI7500 system using the GoTaq® qPCR Master Mix (Promega). All data were normalized to β -actin expression. Relative RNA expression was calculated using the $2^{-\Delta\Delta CT}$ method. Detailed information of primers was listed in Supplemental Table 2.

2.2.6 PPI network analysis and Pearson correlation test.

The protein-protein interaction (PPI) network was created from the "string" database for target genes. The goal is to discover the interaction of target genes and their interactions with other proteins. The expression matrix of the 3 datasets was merged after removing batch effect and the Pearson correlation test was adopted for evaluation of the interactions between DKD related genes at the mRNA level using R.

2.3 Statistical analysis

All values are expressed as the mean \pm SEM. Statistical analysis was performed using the statistical package SPSS for Windows Version 7.51 (SPSS, Inc, Chicago, IL, USA). Results were analyzed using Student t test for

multiple comparisons. Statistical significance was detected at the 0.05 level.

3.Results

3.1 Differential expression gene

Based on our RNA-seq results, a total of 124 differentially expressed mRNAs were identified, including 58 up-regulated genes and 66 down-regulated genes. After screening the genes with differential expression in GSE86300, 331 genes with differential expression were determined, including 181 up-regulated genes and 151 down-regulated genes. In GSE184836 DEGs, there were 315 differentially expressed genes, including 107 up-regulated genes and 208 down-regulated genes. The 3 datasets were analyzed according to the criteria $|\log_2 FC| > 1$ and $p\text{-value} < 0.05$. To visualize the differentially expressed genes, we constructed heatmaps (Fig. 2A,C,E) and volcano curves (Figs. 2B,D,F) and then created a Venn diagram to obtain 10 co-expression genes among the 3 datasets (Fig. 2G).

3.2 Enrichment analysis

GO functional annotation and KEGG pathway enrichment analysis were performed for the DEGs from the 3 datasets. The GO analysis results of our RNA-seq showed that the BP analysis was mainly enriched in the steroid metabolic process, lipid localization, cellular ketone metabolic process, fatty acid metabolic process, organic hydroxy compound metabolic process, response to fatty acid and lipid transport, while CC is mainly concentrated in chylomicron, very-low-density lipoprotein particle and triglyceride-rich plasma lipoprotein particle. The top 3 of MF are oxidoreductase activity, monooxygenase activity, alditol: NADP+ 1-oxidoreductase activity respectively (Fig. 3A). KEGG pathway analysis showed that the top 3 enrichment pathways of the DEGs are cholesterol metabolism, steroid hormone biosynthesis and bile secretion (Fig. 3B). GSE86300 analysis showed that the BP of DEGs was mainly in the fatty acid metabolism, steroid metabolism, and regulation of lipoprotein lipase activity (Fig. 3C). At the same time, KEGG analysis showed they were mainly in the cholesterol metabolism, complement and coagulation cascades, and legionellosis pathway (Fig. 3D). GSE184836 analysis indicated that organic hydroxy compound metabolic process, steroid metabolic process, fatty acid metabolic process as the top 3 BP (Fig. 3E). Meanwhile, KEGG analysis manifested that butanoate metabolism, malaria and pyruvate metabolism as the top 3 (Fig. 3F).

3.3 Venn diagram

10 overlapping genes, namely, Ltc4s, Cd36, Slc1a4, Slc22a19, Lpl, Akr1c14, Apoh, Fmo5, Abcc4, Ugt8 were identified from the 3 datasets by creating a Venn diagram. The expression levels and trends of the above 10 genes in 3 databases were listed in Table 1.

3.4 Identification of 10 overlapping genes expression by qRT-PCR

The mRNA levels of the 10 overlapping genes were verified by qRT-PCR in DKD and control mice kidney tissues, meanwhile, the results indicated that the mRNA levels of Ugt8a, Apoh, Akr1c14, Lpl, Slc1a4 and Cd36 were down-regulated, while Abcc4 and Ltc4s were up-regulated, these changes were statistically significant ($p < 0.05$). In addition, qRT-PCR results of Fmo5 showed that its expression was up-regulated in DKD kidney tissues, which is contrary to the sequencing results. And the expression of Slc22a19 showed no statistical significance in the DKD group compared with the Control ($p > 0.05$) (Fig 4). In conclusion, the mRNA expression levels of these 8 genes verified by qRT-PCR were consistent with the sequencing results (Ugt8a, Apoh, Akr1c14, Lpl, Slc1a4, Cd36, Abcc4, Ltc4s).

3.5 Protein interaction analysis

The “string” database was used for PPI analysis. The results of PPI analysis of the above verified 8 genes were

similar to those of functional annotation of GO and KEGG Pathway Enrichment Analysis (Fig. 5A-B). The 8 genes apparently showed mainly correlation with lipid metabolism, and of these 8 genes, 3 had an obvious interaction relationship, namely Cd36, Apoh, and Lpl (Fig. 5C). Similarly, the enrichment analysis of the BP of 8 genes revealed that the above 3 genes were all enriched in the triglyceride metabolic process. Additional information of the 8 verified genes related to BP analysis is listed in Table2. In addition, through the Pearson correlation test, there were prominently positive or negative correlations between the DKD related genes at the mRNA levels (Fig. 5D).

4. Discussion

In recent years, the consequences of diabetes complications have gradually attracted people's attention. With the increasing incidence of DKD, it brings a heavy medical burden to society. Nowadays, the clinical diagnosis of DKD mainly depends on the protein content in urine, and the treatment aims to reduce the protein content in urine. With the development of sequencing technology, we now realize that genes play a key role in the diagnosis, occurrence, progression and treatment of DKD. Thus, many mRNAs and non-coding RNAs associated with DKD have been discovered and supported by a large number of studies.

In our study, we found 8 genes whose expression levels were significantly altered in the kidney tissues of DKD mice. Cd36, Ugt8a (UDP-galactosyltransferase 8A), Apoh (apolipoprotein H), Akr1c14 (aldoketo reductase family 1, member C14), Lpl (lipoprotein lipase), and Slc1a4 (solute carrier family 1 member 4) were downregulated, whereas the expression levels of Abcc4 and Ltc4s were upregulated. Enrichment analysis of genes with distinct expression differences showed that these genes were involved in the biological processes of KEGG pathways such as steroid metabolism, lipid localization, cellular ketone metabolism, fatty acid metabolism, cholesterol metabolism, steroid hormone biosynthesis and bile secretion. Analysis of the 8 genes verified by qRT-PCR indicated that the function of these genes was mainly related to lipid metabolism.

The glucose and lipid metabolism disorder has become a very common metabolic defect, and is also an important factor leading to DKD. Researchers have confirmed that dyslipidemia and the increased free fatty acids (FFA) are risk factors for insulin resistance and glucolipid toxicity is an important cause of T2DM^[10]. Lipid toxicity is mainly involved in renal damage related to lipid toxicity through the activation of inflammation, oxidative stress, mitochondrial dysfunction and apoptosis^[11], and increased lipophagy ameliorates renal damage, lipid deposition, oxidative stress and apoptosis in the kidney^[12].

There are a number of studies on CD36, it is believed to be involved in fatty acid uptake, apoptosis, angiogenesis, phagocytosis, inflammation and atherosclerosis^[13]. Some scholars have proposed that high glucose exacerbates fatty acid uptake and deposition through increased expression of the class B scavenger receptor CD36 via the AKT-PPAR γ pathway and that CD36 in plasma may be a biomarker for T2DM^[14, 15]. CD36 knockdown prevents renal tubular injury, tubulointerstitial inflammation, and oxidative stress in 16 weeks db/db mice^[16]. In addition to these, data suggests that CD36 deficiency aggravates hepatic lipid accumulation and reduced VLDL secretion in ob/ob mice^[17]. And the loss of CD36 in mice leads to phenotypes such as lymphatic drainage, visceral fat, and glucose intolerance, which increases the risk for T2DM^[18].

In addition, studies have shown that in C57BL/6J mice, Lpl was mainly expressed intracellular and restricted to the proximal tubule^[19]. In the DKD group, renal LPL mRNA expression was significantly decreased, and down-regulation of renal LPL increased the level of triglyceride (TG) in renal tissue^[20]. Apoh is involved in a variety of physiological processes, including lipoprotein metabolism, coagulation, and antiphospholipid autoantibody production^[21]. It is also associated with BMI in diabetics and cardiovascular risk factors and is considered an

anti-obesity factor^[22]. Ugt8a encodes galactosylceramide synthase, and alteration in expression levels can lead to impaired lipid metabolism. The role of Ugt8a in regulating lipid metabolism in the nervous system has been confirmed by a number of studies^[23], and some experts have suggested that the elevated Ugt8 levels may be a protective compensatory response in DKD to prevent podocyte degeneration by enhancing their survival^[24]. The protein encoded by Ltc4s is an enzyme that catalyzes the synthesis of leukotriene C4 by linking leukotriene A4 to reduced glutathione. Leukotrienes are thought to mediate anaphylaxis and inflammatory conditions^[25]. Unilateral ureteral obstruction (UUO), folate nephropathy and orthologous mouse model were established and Ltc4s synthase was knocked down, it was found that fibrosis was reduced and renal function was improved in the Ltc4s knockout model^[26]. Akr1c14, a metabolic enzyme involved in the reduction of aldehydes and ketones and glycoside metabolic process, has been shown to be downregulated in adipocytes in models of adipose tissue inflammation and thus is thought to play a role in the maintenance of normal adipocyte metabolism^[27]. Abcc4 was highly expressed in the kidney of mice. Aberrant hypomethylation of Abcc4 was detected in C57BLKS/J db/db mice^[28], studies have also shown that the expression of Mrp4/Abcc4 is increased in metabolic tissues such as liver and kidney in obese and diabetic patients^[29]. Slc1a4 is highly expressed in the central nervous system, and relevant studies are still lacking. Further studies on the mechanism of action of Slc1a4 in DKD are needed in the future.

The present study identified novel molecular targets by integrating our RNA-seq and microarray datasets in GEO, we found 8 genes differentially expressed in the kidney tissues of DKD mice and verified by qRT-PCR. Through GO, KEGG and PPI analysis, 3 genes caught our attention: Lpl, Apoh and Cd36, these 3 genes were not only differentially expressed in DKD mice kidney tissue, but also closely related to triglyceride metabolism, the results of the “String” database analysis indicated that these 3 genes may have mutual regulation, and we can see the other proteins that interact with them, for example, they may interact with Angptl4, Apoa1, Apoa2 and Apob. ANGPTL4 has been studied as a potent inhibitor of Lpl that regulates cellular uptake of triglycerides and promotes fatty acid oxidation^[30], Binod^[31] found that the expression of Cd36 increased in Angptl4^{-/-} macrophages. Apo a and Apo b are mainly studied in obesity and cardiovascular diseases, studies suggest that ApoA1, Apo B, and Apo B/ApoA1 ratio have been regarded as the predictors of microvascular and macrovascular complications of diabetes. We have seen less research on kidney disease, but we speculate from our current study that it may play an important role in kidney disease, more experiments will investigate the mechanism in the future.

However, the present study has certain limitations. First, we did not perform a joint analysis of biochemical indicators of mice, which is a defect of this study. Second, the DKD mice models are less representative than kidney samples from DKD patients because they may have only moderate renal abnormalities. Third, the array data came from the later stage of DKD, and therefore, the expression levels of certain genes may not be identical to those in the early stage. For instance, the protein levels of CD36 have been reported to be upregulated in this disease, while this gene was downregulated in our study. In addition, the novel potential target genes should be further verified in experimental studies. The present results were obtained using a bioinformatics screening to identify several novel DEGs between DKD and control groups, and which suggested that these 8 genes have vital roles in the pathological process of lipid metabolism in DKD. Importantly, the information provided in this study was not limited to the 8 verified genes, but maybe included certain other typical DEGs. The current results provide a worthy resource for future research on DKD.

5. Conclusion

Our study, based on RNA-seq results, the GEO database and qRT-PCR, identified 8 significant dysregulated DEGs, which play an important role in lipid metabolism and provide novel targets for diagnosis and treatment of DKD.

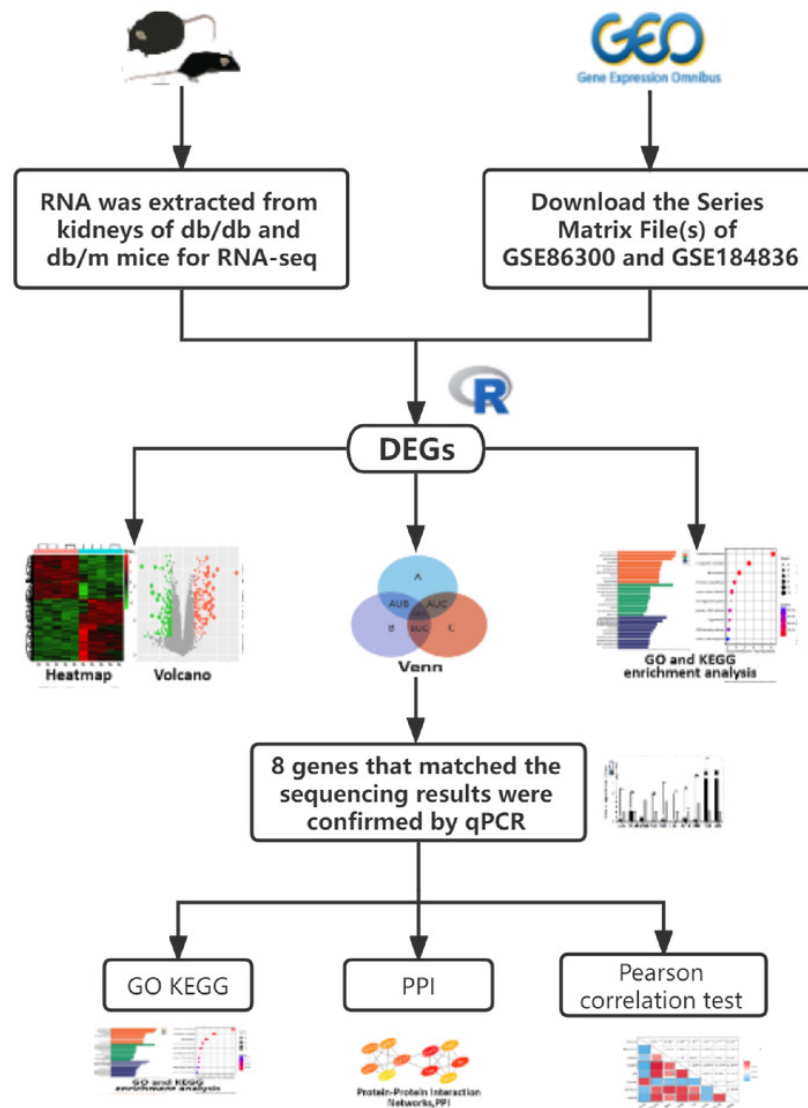

Figure 1. The workflow of this study

Figure 2

figure 2

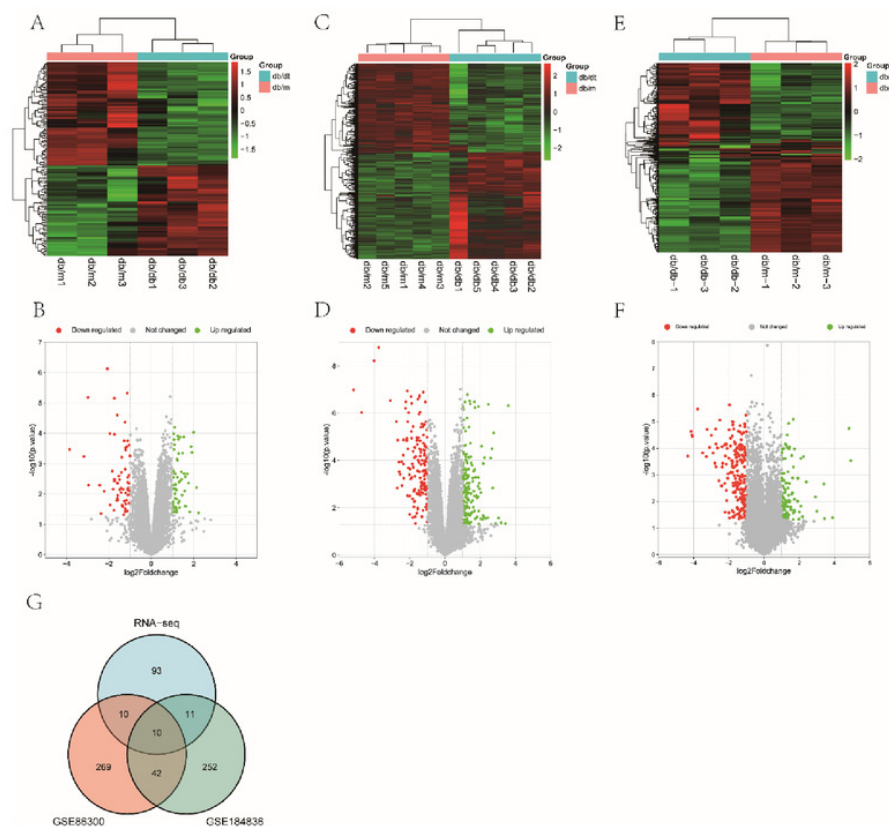

Figure 2 Differential expression analysis of our RNA-seq and two GEO datasets (GSE86300 and GSE184836). (a) Heatmap of DEGs in our RNA-seq. (b) Volcano map of our RNA-seq. A total of 58 upregulated and 66 downregulated DEGs were identified between the DKD and the Control group. (c) Heatmap of DEGs in GSE86300. (d) Volcano map of DEGs in GSE86300. A total of 181 up-regulated and 151 down-regulated DEGs were identified between the DKD and the Control group. (e) Heatmap of DEGs in GSE184836. (f) Volcano map of DEGs in GSE184836. A total of 107 up-regulated and 208 down-regulated DEGs were identified between the DKD and the control group. (g) Venn diagram of three DEGs groups. A total of 10 co-expression genes were obtained. In volcano map, green bubbles mean up-regulated genes, red bubbles mean down-regulated genes, and gray bubbles mean non-significant genes. In heatmap, red mean up-regulated genes, green mean down-regulated genes. ($|\log_2 FC| > 1$ and p -value < 0.05)

Figure 3

figure 3

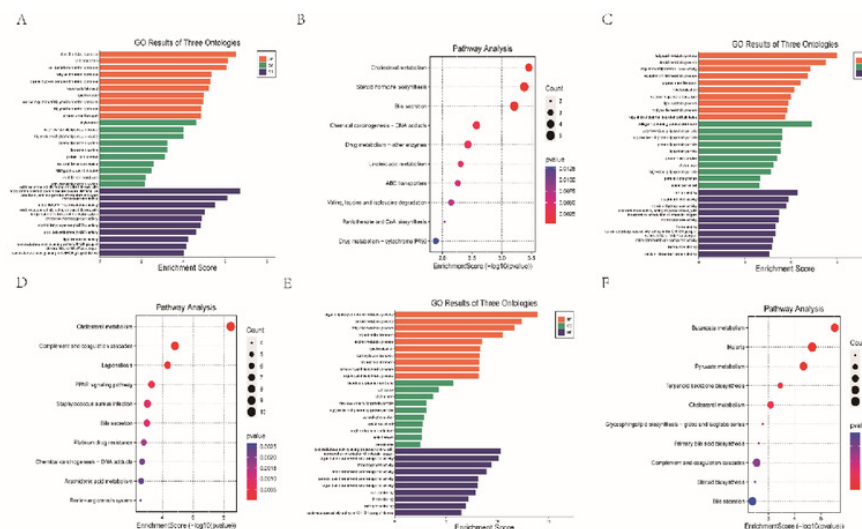

Figure 3. Bar graph of GO Annotation and dot plot of KEGG pathway enrichment analysis of DEGs. (a, b) Our RNA-seq (Top 10). (c, d) GSE86300 (Top 10). (e, f) GSE184836 (Top 10). In the dot plot, the color represents the p -value, and the size of the spots represents the gene number.

Figure 4

figure 4

Figure 4. The relative mRNA expression of 10 overlapping genes in DKD and control group determined by qRT-PCR. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Figure 5

figure 5

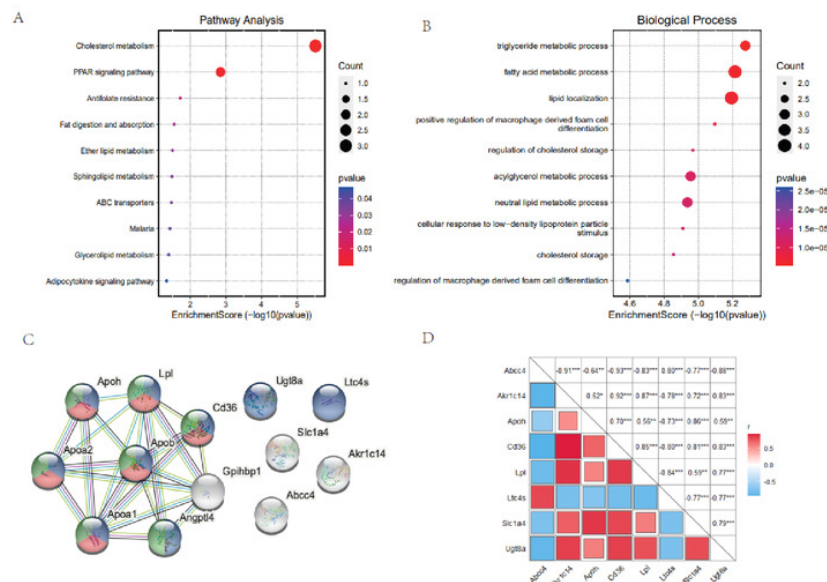

Figure 5 (a) Dot plot of KEGG pathway enrichment analysis of verified 8 genes, in the dot plot, the color represents the p-value, and the size of the spots represents the gene number. (b) Bar plot of GO enrichment analysis of verified 8 genes. (c) PPI network of verified 8 DEGs, which also showed that several other genes were involved. In the PPI analysis, green represents the cholesterol metabolic pathway, red represents the triglyceride metabolic process and blue represents the lipid metabolic process, white has no meaning. (d) Pearson correlation test between 8 DKD related genes, blue represents negative correlation, while red represents positive correlation.
