Background: Personality is the major predictor of people's subjective well-being (i.e., positive affect, negative affect, and life satisfaction). Recent research in countries with high-income and strong self-transcendent values shows that well-being depends on multidimensional configurations of temperament and character traits (i.e., Joint Personality Networks) that regulate the way people learn to adapt their habits to be in accord with their goals and values, rather than individual traits. To evaluate the prevalence and the associations of different Joint Personality (temperament-character) Networks with well-being in a low-income country with weak self-transcendent values, we tested their association in Bulgarian adults, a population known to have strong secular-rationalist values but weak self-transcendent values.

Method: The sample consisted of 443 individuals from Bulgaria (68.70% females) with a mean age of 34 years ($SD = 15.05$). Participants self-reported personality (Temperament and Character Inventory), affect (Positive Affect Negative Affect Schedule), and life satisfaction (Satisfaction with Life Scale). The personality scores were used for profiling through latent profile analysis and latent class analysis based on temperament configurations (i.e., Temperament Profiles) of high/low scores of Novelty Seeking (N/n), Harm Avoidance (H/h), Reward Dependence (R/r), and Persistence (P/s); and character configurations (i.e., Character Profiles) of high/low scores of Self-Directedness (S/s), Cooperativeness (C/c), and Self-Transcendence (T/t).

Results: We found two Temperament Profiles and two Character Profiles that clustered into two distinctive Joint Personality Networks. All individuals in Joint Personality Network 1 had a Reliable (nhRP) Temperament Profile in combination with an Organized (SCT) Character Profile (i.e., a stable temperament and a healthy character configuration). About 71.9% in Joint Personality Network 2 had an

Apathetic (sct) Character Profile in combination with Methodical (nHrp) or Reliable (nhRP) Temperament Profiles, while 28.1% had a Methodical (nHrp) Temperament Profile in combination with an Organized Character Profile (SCt). Few people with high self-expressive values (i.e., high in all three character traits) were found. Individuals with a Joint Personality Network 1 with strong secular-rationalist values reported higher levels of positive affect and life satisfaction ($p < .001$), while individuals with a Joint Personality Network 2 reported higher levels of negative affect ($p < .001$).

Conclusions: Although a stable temperament and a healthy character were separately important for well-being, it was clear that it was the interaction between such temperament and character configuration what yielded greater levels of subjective well-being. Nevertheless, future research needs to investigate this interaction further to evaluate other cultures with variable configurations of personality traits and values.

Abstract

31 **Background:** Personality is the major predictor of people's subjective well-being (i.e., positive
32 affect, negative affect, and life satisfaction). Recent research in countries with high-income and
33 strong self-transcendent values shows that well-being depends on multidimensional configurations
34 of temperament and character traits (i.e., Joint Personality Networks) that regulate the way people
35 learn to adapt their habits to be in accord with their goals and values, rather than individual traits.
36 To evaluate the prevalence and the associations of different Joint Personality (temperament-
37 character) Networks with well-being in a low-income country with weak self-transcendent values,
38 we tested their association in Bulgarian adults, a population known to have strong secular-
39 rationalist values but weak self-transcendent values.

40 **Method:** The sample consisted of 443 individuals from Bulgaria (68.70% females) with a mean
41 age of 34 years ($SD = 15.05$). Participants self-reported personality (Temperament and Character
42 Inventory), affect (Positive Affect Negative Affect Schedule), and life satisfaction (Satisfaction
43 with Life Scale). The personality scores were used for profiling through latent profile analysis and
44 latent class analysis based on temperament configurations (i.e., Temperament Profiles) of high/low
45 scores of Novelty Seeking (N/n), Harm Avoidance (H/h), Reward Dependence (R/r), and
46 Persistence (P/s); and character configurations (i.e., Character Profiles) of high/low scores of Self-
47 Directedness (S/s), Cooperativeness (C/c), and Self-Transcendence (T/t).

48 **Results:** We found two Temperament Profiles and two Character Profiles that clustered into two
49 distinctive Joint Personality Networks. All individuals in Joint Personality Network 1 had a
50 Reliable (nhRP) Temperament Profile in combination with an Organized (SCt) Character Profile
51 (i.e., a stable temperament and a healthy character configuration). About 71.9% in Joint
52 Personality Network 2 had an Apathetic (sct) Character Profile in combination with Methodical
53 (nHrp) or Reliable (nhRP) Temperament Profiles, while 28.1% had a Methodical (nHrp)
54 Temperament Profile in combination with an Organized Character Profile (SCt). Few people with
55 high self-expressive values (i.e., high in all three character traits) were found. Individuals with a
56 Joint Personality Network 1 with strong secular-rationalist values reported higher levels of positive
57 affect and life satisfaction ($p < .001$), while individuals with a Joint Personality Network 2 reported
58 higher levels of negative affect ($p < .001$).

59 **Conclusions:** Although a stable temperament and a healthy character were separately important
60 for well-being, it was clear that it was the interaction between such temperament and character
61 configuration what yielded greater levels of subjective well-being. Nevertheless, future research
62 needs to investigate this interaction further to evaluate other cultures with variable configurations
63 of personality traits and values.

68

Introduction

69 Personality is the major factor and predictor of people's subjective well-being. Some researchers
70 have argued that it is so because personality is related to the way people emotionally react (e.g.,
71 how intensively, duration) to life experiences (Kim-Prieto et al., 2005). However, personality is
72 more than emotional responses to life events or temperamental dispositions, which do not account
73 for environmental learning experiences regulated by our character (i.e., our goals and values)
74 (Cloninger, 2004). Consideration of only a person's temperament limits the concept of personality
75 to traits that are emotion-based and moderately stable (McAdams, 2001). Instead, the science of
76 human well-being (Cloninger, 2004; Cloninger & Cloninger, 2020) needs to: (a) account for both
77 between- and within-individual differences in nonintentional (i.e., temperament) and intentional
78 (i.e., character) domains of personality (Cervone, 2005)—people do not only differ between each
79 other, which describes how people generally are in relation to others; but also differ within
80 themselves in the way their temperament and character traits are organized, as we need to
81 understand in order to predict how and why people behave as they do; (b) consider the large
82 evidence of intraindividual variability across personality profiles (Ryan & Sackett, 2012), (c)
83 account for the dynamics of personality development as a set of learning systems that adapt in a
84 predictable and integrative manner over time (Cloninger et al, 1997; Zwir et al, 2020ab, 2022),
85 and (d) consider recent molecular studies showing that the basic unit of personality are
86 multidimensional profiles of temperament and character, not single traits (Cloninger & Zwir, 2018;
87 Zwir et al., 2020ab, 2022).

88 In this context, Cloninger's biopsychosocial model (Cloninger et al., 1993) decomposes
89 personality in two domains comprised of seven personality dimensions that are based on robust
90 research on the differences in the major brain systems for procedural versus propositional learning.

91 According to Cloninger (2004), the temperament domain reflects the basic organization of
92 independently different brain systems for the activation, maintenance, and inhibition of behavior
93 in response to stimuli. The four temperament dimensions are defined in terms of individual
94 differences in behavioral learning mechanisms shared by all animals, explaining responses to
95 novelty and signals of reward or relief of punishment (Novelty Seeking), responses to signals of
96 punishment or non-reward (Harm Avoidance), responses to social and attachment rewards
97 (Reward Dependence), and the maintained response to previously rewarded behavior with
98 intermittent reinforcement (Persistence). In contrast, the character domain involves individual
99 differences in self-concepts about goals and values (Cloninger, 2004), which depend on brain
100 systems that developed later in evolution (Cloninger, 2009; Zwir et al., 2021). Character is
101 comprised of three dimensions: Self-Directedness (based on the concept of the self as an
102 autonomous individual) allows the individual to engage in purposeful actions because the
103 individual has a “sense of following a meaningful direction in one’s life” (Cloninger, 2004, p.
104 120); Cooperativeness (based on the concept of the social self) allows the individual to be tolerant
105 and flexible about choices regarding goals because thought and behavior are based on mutual
106 interests with other persons; and Self-Transcendence (based on the concept of the self with values
107 derived from awareness of being an integral aspect of a larger whole, such as humanity, nature,
108 and possibly the universe and its source) allows the individual to intuitively recognize the values
109 and meaning in all things (see Table 1 for a detailed description of the different personality
110 dimensions). In short, character allows us to act intentionally and interpret the meaning of what
111 we experience, which in turn allows us to self-regulate our emotional reactions and even our habits
112 (Cloninger, 2004; Moreira et al., 2021a). Due to its distinction between nonintentional (i.e.,
113 temperament) and intentional (i.e., character) domains of personality, Cloninger’s biopsychosocial

114 model is appropriate for assessment of both within-person learning processes and between-person
115 differences (Cervone, 2005)—that is, the way people differ from others but also the processes that
116 motivate and regulate adaptive processes occurring within the individual.

117 Table 1 should be about here

118 Hence, when individuals are asked to assess their subjective well-being, the recollection of
119 a happy life is not exclusively and unconsciously dictated by how their temperament leads them
120 to emotionally react (Cloninger, 2004). In fact, our recent genomic research shows that most of
121 the genes associated with character are long-non-coding RNA genes that regulate the expression
122 of protein-coding genes, coordinate the co-expression of sets of genes, and influence epigenetic
123 processes. In contrast, most of the genes associated with temperament are protein-coding genes
124 involved in cellular processes of synaptic plasticity, associative conditioning, and related processes
125 of stress reactivity and neurotransmission (Zwir et al., 2020ab). Moreover, the genes encoding
126 human character are associated with one brain network for higher cognitive processes involving
127 intentional self-control and another brain network for self-awareness, whereas the genes encoding
128 human temperament are enriched in highly conserved molecular pathways that are present in all
129 animals and that are activated in experimental animals by associative conditioning in response to
130 extracellular stimuli (Cloninger & Cloninger, 2020). In other words, despite the fact that human
131 personality is moderately heritable (e.g., Gillespie et al., 2003; Ando et al., 2004; Garcia et al.,
132 2013), the path to well-being and a resilient life depends on processes of learning, development,
133 and integration of character development, such as self-actualization and identity formation that are
134 optimized by the self-awareness of human beings, which allows the unique capacities of human
135 self-aware consciousness (Cloninger & Cloninger, 2020). Put in another way, we inherit the way
136 we learn, so nature and nurture are both always important.

137 We have replicated these molecular findings in three large independent genome-wide
138 association studies from Finland, Germany, and South Korea (Zwir et al., 2020ab, 2022).
139 Moreover, in these three independent samples, we uncovered three clusters of similar numbers of
140 people with distinct combinations of Temperament and Character Profiles, which we refer to as
141 Joint Personality (temperament-character) Networks. In short, temperament and character traits
142 are expressions of the activity of three genetic-environmental networks that regulate healthy
143 longevity and dissociable systems of learning and memory by nearly disjoint sets of genetic and
144 environmental influences. Indeed, since personality is a complex adaptive system or a whole-
145 system unit, it should be best studied by analyzing patterns of information rather than single traits
146 (Cloninger et al., 1997; see also Bergman & Wångby, 2014).

147 These three Joint Personality Networks were subsequently confirmed in a Portuguese
148 sample of adolescents, where individuals with a stable or reliable Temperament Profile (low in
149 Novelty Seeking, low in Harm Avoidance, high in Reward Dependence, and high in Persistence)
150 in conjunction with a healthy or Creative Character Profile (high in all three character dimensions)
151 reported fewer clinical problems and greater engagement with school (Moreira et al., 2021b).
152 Among adults, individuals with a Creative (high in all three character traits) or an Organized
153 Character Profile (high in Self-Directedness and Cooperativeness but low in Self-Transcendence)
154 consistently report the highest levels of well-being, healthy longevity, optimal cardiovascular
155 health, including healthy lifestyle as well as reduced risk for chronic diseases (Cloninger, 2004).
156 Having a Creative Character Profile is also linked with better heart rate variability or vagal tone in
157 24-hour recordings of heart rhythms (Zohar et al., 2013). To the best of our knowledge, the three
158 Joint Personality Networks have been replicated in our molecular studies (Zwir et al., 2020ab,
159 2022) and the Portuguese study (Moreira et al., 2021b). In addition, these Joint Personality

160 (temperament-character) Networks closely resemble groups identified in large-scale longitudinal
161 studies of social values: cultural creatives (i.e., post-materialists with strong self-expressive,
162 prosocial, and self-transcendent values corresponding to those with Reliable-Creative Personality
163 Networks), materialists (i.e., with secular-rationalist values corresponding to those with Reliable-
164 Organized Personality Networks), and traditionalists (i.e., those whose values and behavior depend
165 mainly on authority-dependent conventions and habits corresponding to those with temperaments
166 weakly regulated by character) (Ray & Anderson 2000; Inglehart 2018a). We initially identified
167 the three networks in countries with different cultural values and environmental conditions
168 (Finland, Germany, and South Korea). We have replicated our findings in a lower income country
169 (Portugal), but recognize that there is a need to examine other cultures, such as Bulgaria, which
170 has been shown in the World Values Survey to have strong secular-rationalist values typical of
171 egocentric people with a Reliable-Organized Personality Network, but have weak self-expressive,
172 prosocial, and self-transcendent values, which is unlike people in the Reliable-Creative Personality
173 Network (Inglehart, 2018a). The levels of well-being in groups of people with materialist or
174 secular-rationalist values are intermediate to those of people with creative cultural values and those
175 with traditional values (Zwir et al., 2022; Inglehart 2018ab), so Bulgaria represents an interesting
176 contrast to other countries in which we have assessed the associations between well-being and
177 Joint Personality Networks.

178 In this line of thinking, we investigated the prevalence of different Temperament and
179 Character profiles and Joint Personality (temperament-character) Networks and differences in
180 subjective well-being (i.e., positive affect, negative affect, and life satisfaction) between
181 individuals in a population of Bulgarian adults. Importantly, since a culture's distinctive values
182 are often a product of its history, our Bulgarian sample is phenomenologically relevant to the

183 Balkan's history of repeated colonization, which might have ingrained people in Bulgaria with the
184 specific capacity for balancing different and even conflicting values—"Balkan people survived
185 colonization by learning to live 'at the edge of compromise' between their own values and the
186 values of their colonizers", that is, Balkan pluralism (Stoyanov & Fulford, 2021, pp. 171). In fact,
187 as mentioned, Bulgarians have been found to have strong secular-rationalist values and weak self-
188 expressive values in the World Values Survey (Inglehart, 2018ab) so we hypothesized that people
189 with Reliable-Organized Personality Networks would be frequent whereas those with Reliable-
190 Creative Personality Networks would be few in number. In other words, we expected that our
191 Bulgarian sample would be characterized by a very self-directed and cooperative but pragmatic
192 and skeptical outlook on the world (i.e., high Self-Directedness, high Cooperativeness, and low in
193 Self-Transcendence).

194

Method

195 Ethical Statement

196 The study was approved by the National Ethics Committee of the Bulgarian Association of Health
197 Care Professionals (Protocol No. 2/10.05.2021).

198 Participants

199 The sample consisted of 443 individuals from Bulgaria (age range 18 to 65; about 68.70% females)
200 with a mean age of 34 years ($SD = 15.05$). Subjects provided verbal consent to participate in the
201 study. In contrast to the linear analyses originally conducted with the same data (see Angelova,
202 2020), we used person-oriented analyses by first clustering individuals in distinct Temperament
203 Profiles and Character Profiles (see the Supplementary Material for details). Second, we combined
204 individuals' Temperament and Character Profiles to cluster them in Joint Personality
205 (temperament-character) Networks that represent personality as a complex adaptive system.

206 **Measures**

207 ***Personality***

208 We used the validated official Bulgarian version (Tilov et al., 2012) of the Temperament and
209 Character Inventory (Cloninger et al., 1993) to measure the four temperament traits and the three
210 character traits in Cloninger's biopsychosocial model of personality: Novelty Seeking (e.g., "I
211 often try new things just for fun or thrills, even if most people think it is a waste of time"), Harm
212 Avoidance (e.g., "I often feel tense and worried in unfamiliar situations, even when others feel
213 there is little to worry about"), Reward Dependence (e.g., "I like to discuss my experiences and
214 feelings openly with friends instead of keeping them to myself"), Persistence (e.g., "I often push
215 myself to the point of exhaustion or try to do more than I really can"), Self-Directedness (e.g., "In
216 most situations my natural responses are based on good habits that I have developed"),
217 Cooperativeness (e.g., "I often consider other persons' feelings as much as my own"), and Self-
218 Transcendence (e.g., "I sometimes feel so connected to nature that everything seems to be part of
219 one living organism"). The version used here contains 140 items using a 5-point Likert scale (1 =
220 *strongly disagree*, 5 = *strongly agree*) and had good reliability with the following *Cronbach's*
221 *alphas*: .64 for Novelty Seeking, .84 for Harm Avoidance, .75 for Reward Dependence, .89 for
222 Persistence, .86 for Self-Directedness, .81 for Cooperativeness, and .81 for Self-Transcendence
223 (Angelova, 2020).

224 ***Subjective Well-Being***

225 We used the Positive Affect Negative Affect Schedule – Short Form (Watson et al., 1988) to
226 operationalize the affective component of subjective well-being. This is a 20-item scale designed
227 to measure positive affect and negative affect as independent dimensions. Participants are
228 instructed to rate to what extent they have experienced 10 positive (e.g., strong, proud, interested)

229 and 10 negative emotions (e.g., afraid, ashamed, nervous) during the last weeks, using a 5-point
230 Likert scale (1 = *very slightly*, 5 = *extremely*). In the present study, the positive affect scale showed
231 a *Cronbach's alpha* of .85 and the negative affect scale showed a *Cronbach's alpha* of .88
232 (Angelova, 2020).

233 Moreover, we used the Satisfaction with Life Scale (Diener et al., 1985) to operationalize
234 the cognitive component of subjective well-being. This scale has five statements (e.g., “In most
235 ways my life is close to my ideal”) that respondents are asked to rate their level of agreement to
236 using a seven-point Likert scale (1 = *strongly disagree*, 7 = *strongly agree*). The Satisfaction with
237 Life Scale showed a *Cronbach's alpha* of .83 in the present study (Angelova, 2020).

238 Hence, subjective well-being was operationalized as composed of three individual
239 variables: positive affect, negative affect, and life satisfaction. Each subjective well-being variable
240 was calculated using the mean of total scores of each of the scales.

241 **Statistical Procedure**

242 For the first phase, explorative analyses, we calculated zero-order correlations between the
243 temperament and character dimensions and the subjective well-being dimensions (see also
244 Angelova, 2020). For the second phase, we used latent profile analysis (LPA) to identify and
245 cluster the study sample into (a) Temperament Profiles, and (b) Character Profiles (see the detailed
246 procedure in the Supplementary Material). These models were estimated using standardized mean
247 scores for each of the four temperament and three character dimensions, respectively (continuous
248 variables). For the third phase, our main set of analyses, we used latent class analysis (LCA) to
249 cluster individuals into Joint Personality (temperament-character) Networks. This model was
250 estimated by combining participants' assigned Temperament Profiles and Character Profiles
251 (categorical variables). For both the LPA and LCA, we determined the optimum number of latent

252 profiles or networks by comparing the fit of a series of models with increasing numbers of profiles.
253 Model fit was compared using the Akaike Information Criterion (Akaike, 1974), Bayesian
254 Information Criterion (BIC; Schwarz, 1978), sample-size adjusted BIC (Sclove, 1987), and
255 entropy (Celeux & Soromenho, 1996). For LPA, we also used an Analytic Hierarchy Process
256 (Akogul & Erisoglu, 2017) to help determine the optimal number of profiles. In both the second
257 and third phases, using standardized scores for all measures (*z-scores*), we conducted a series of
258 MANOVA:s to test differences in personality and subjective well-being (for the full analyses of
259 the second phase, Temperament Profiles and Character Profiles, please see the Supplementary
260 Material). The use of *z-scores* allowed us to compare the relevant variables (personality
261 dimensions or subjective well-being constructs) within each profile or network (e.g., to test if Harm
262 Avoidance among individuals with a specific profile differs from their own levels of Novelty
263 Seeking, if positive affect among individuals with a specific profile differs from their own levels
264 of life satisfaction, and etcetera).

265

Results

266 Phase 1: Correlations between Personality Traits and Subjective Well-Being

267 Table 2 displays the zero-order correlations between temperament and character traits and
268 subjective well-being. Regarding Temperament, as expected, Harm Avoidance was negatively
269 associated to positive affect ($r = -.40, p < .001$) and life satisfaction ($r = -.29, p < .001$), but
270 positively related to negative affect ($r = .42, p < .001$); and Persistence was positively related to
271 positive affect ($r = .56, p < .001$) and life satisfaction ($r = .31, p < .001$). Regarding Character, also
272 as expected, Self-Directedness was positively associated to positive affect ($r = .37, p < .001$) and
273 life satisfaction ($r = .39, p < .001$), and negatively related to negative affect ($r = -.47, p < .001$);
274 Cooperativeness was also positively associated to positive affect ($r = .37, p < .001$) and life

275 satisfaction ($r = .39, p < .001$), and negatively related to negative affect ($r = -.47, p < .001$); and
276 Self-Transcendence was positively associated to positive affect ($r = .32, p < .001$). The lowest
277 correlation, between personality traits and subjective well-being constructs, was that between
278 Novelty Seeking and negative affect ($r = .01, p = .882$). See also Angelova, 2020.

279 Please insert Table 2 about here

280 **Phase 2: Prevalence of Temperament Profiles and Character Profiles and Differences in** 281 **Subjective Well-Being**

282 Before conducting the latent class analyses (LCA) in phase three of our study, we calculated
283 Temperament Profiles and Character Profiles (phase 2) separately using latent profile analyses
284 (LPA). The LPA revealed two Temperament Profiles (profile 1 which included 18.2% of the
285 participants and profile 2 which included 81.8% of the participants) and two Character Profiles
286 (profile 1 which consisted of 23.1% of participants and profile 2 with 76.9% of the participants).
287 For more details, please see Supplementary Materials, here we only summarize the results and
288 derived conclusions.

289 Individuals in both Temperament Profiles reported low levels of Novelty Seeking ($n =$ low
290 Novelty Seeking) and were symmetrically different regarding high/low Harm Avoidance ($H =$
291 high Harm Avoidance/ $h =$ low Harm Avoidance), high/low Reward Dependence ($R =$ high Reward
292 Dependence/ $r =$ low Reward Dependence), and high/low Persistence ($P =$ high Persistence/ $p =$ low
293 persistence). We labeled Temperament Profile 1 Methodical because individuals with this profile
294 are highly cautious due to high Harm Avoidance (H), orderly due to low Novelty Seeking (n), and
295 objective due to the combination of high Harm Avoidance and low Reward Dependence (Hr).
296 Hence suggesting that individuals with the Methodical ($nHrp$) Temperament Profile might be
297 described as inhibited ($nH =$ low Novelty Seeking and high Harm Avoidance), aloof ($Hr =$ High

298 Harm Avoidance and low Reward Dependence), privacy-seeking (nr = low Novelty Seeking and
299 Low Reward Dependence), and having difficulties to initiate anything new because of their
300 inhibitions rooted in their tendency to pragmatism and underachievement (p = low Persistence). If
301 such an individual lacks a well-developed Character Profile, they can be perceived and act as
302 obsessional personalities and find situations that require exposure to public attention to be
303 challenging (Cloninger, 2004). They are, however, not afraid of being rejected (Hr = High Harm
304 Avoidance and low Reward Dependence), hence, making them objective. Conversely, we labeled
305 Temperament Profile 2 Reliable because individuals with this Temperament Profile are stable due
306 to low Novelty Seeking and low Harm Avoidance (nh), warmly sociable due to low Harm
307 Avoidance and High Reward Dependence (hR), traditional because of their low Novelty Seeking
308 and high Reward Dependence (nR), and hard-working due to high Persistence (P). Hence, it is
309 highly likely that individuals with a Reliable (nhRP) Temperament Profile can be trusted to carry
310 out what they are expected to do in a predictable and traditional manner and to develop a mature
311 character (Cloninger, 2004). As expected, a post hoc test with Bonferroni correction (see
312 Supplementary Material) showed that positive affect and life satisfaction were higher among
313 individuals with the Reliable (nhRP) Temperament Profile and negative affect was higher among
314 individuals with the Methodical (nHrp) Temperament Profile ($p < .001$).

315 Individuals in both Character Profiles reported low levels of Self-Transcendence (t = low
316 Self-Transcendence) but symmetrically different levels of high/low Self-Directedness (S = high
317 Self-Directedness/ s = low Self-Directedness) and high/low Cooperativeness (C = high
318 Cooperativeness/ c = low cooperativeness). We labeled Character Profile 1 as Apathetic because
319 individuals with this profile tend to feel victimized and helpless (sc = low Self-Directedness and
320 low Cooperativeness), show very poor judgement (st = low Self-Directedness and low Self-

321 Transcendence), and are distrustful (ct = low Cooperativeness and low Self-Transcendence).
322 Indeed, individuals with an Apathetic (sct = low in all three character traits) Character Profile
323 report the lowest levels of overall well-being and health, report experiencing unhealthy emotions
324 such as anxiety and alienation, and have high rates of mental and physical disorders (Cloninger,
325 2004). In other words, they experience the world from an outlook of separateness, which leads to
326 fear, excessive desire, and false pride or self-reproach. Conversely, we labeled Character Profile 2
327 Organized because individuals with such profile are often perceived as mature leaders (SC = high
328 Self-Directedness and high Cooperativeness), logical (St = high Self-Directedness and low Self-
329 Transcendence), and conventional (Ct = high Cooperativeness and low Self-Transcendence). They
330 are, most of the time, happy and healthy, and seldom need health care (Cloninger, 2004). However,
331 when they face difficult existential challenges, such as severe illness or death, they often lack the
332 necessary outlook of unity and connectedness needed to be resilient through such situations due to
333 low levels of Self-Transcendence (t). As expected, a post hoc test with Bonferroni correction (see
334 Supplementary Material) showed that life satisfaction was higher among individuals with the
335 Organized (SCT) Profile and negative affect was higher among individuals with the Apathetic (sct)
336 Profile ($p < .001$). Positive affect, however, did not differ between individuals with these two
337 Character Profiles. Thus, accentuating that an Organized (SCT) Profile is necessary, but not
338 sufficient for experiencing a happy life.

339 **Phase 3: Joint Personality (temperament-character) Networks**

340 In phase 3, our main set of analyses, we conducted a LCA to investigate the interaction of the
341 distinct Temperament Profiles and Character Profiles as Joint Personality (temperament-character)
342 Networks. We tested four different models with 1 and up to 4 networks (Table 3). All values for
343 Model 2, with two networks, had the best fit to our model (AIC = 840.770, BIC = 861.237, SABIC

344 = 845.370, VLMRT = .0006, LMRT = .0008, and BLRT = <.001). Model 2 consisted of Joint
345 Personality Network 1 which included 68.6% of the participants and Joint Personality Network 2
346 with 31.4% of the participants (see more details in the Supplementary Material).

347 Please insert Table 3 about here

348 Regarding Temperament Profiles, all the individuals in the Joint Personality Network 1 had
349 a Reliable (nhRP) Temperament Profile. In Joint Personality Network 2, as much as 46.8% of the
350 individuals had a Methodical (nHrp) Temperament Profile and 53.2% had a Reliable (nhRP)
351 Temperament Profile. In other words, the number of individuals with the Methodical (nHrp)
352 Temperament Profile and the Reliable (nhRP) Temperament Profile were almost equal in the Joint
353 Personality Network 2; while all individuals allocated to Joint Personality Network 1 had a
354 Reliable (nhRP) Temperament Profile (see Table 4). Regarding Character Profiles, all the
355 individuals in Joint Personality Network 1 had an Organized (SCt) Character Profile. Conversely,
356 28.1% of the individuals clustered in the Joint Personality Network 2 had an Organized (SCt)
357 Character Profile and 71.9% had an apathetic (sct) Character Profile. This means that individuals
358 allocated in the Joint Personality Network 1 had a significantly higher amount of individuals with
359 an Organized (SCt) Character Profile compared to individuals in the Joint Personality Network 2.
360 In sum, while all individuals in the Joint Personality Network 1 had a stable Reliable (nhRP)
361 Temperament Profile in combination with a healthy Organized (SCt) Character Profile, none of
362 the individuals in Joint Personality Network 2 had this stable and healthy personality
363 configuration; instead 71.9% had an Apathetic (sct) Character Profile in combination with
364 Methodical (nHrp) or Reliable (nhRP) Temperament Profiles and the rest (28.1%) had an
365 Organized Character Profile in combination with a Methodical (nHrp) Temperament Profile (see
366 the Supplementary Material for the details).

367 Please insert Table 4 about here

368 ***Differences in Temperament and Character Dimensions within Individuals with Distinct Joint***

369 ***Personality (Temperament-Character) Networks***

370 We found significant differences in personality dimensions within each Joint Personality Network
371 with a Greenhouse-Geisser correction ($F_{(4.78, 1447, 78)} = 9.12, p < .001, \eta^2 p = 0.03, \text{observed power}$
372 $= 1.0$). However, a Bonferroni adjustment test showed that some mean differences were not
373 significant ($p > .05$). Within Joint Personality Network 1, individuals scored highest in Persistence
374 and lowest in Harm Avoidance. Within Joint Personality Network 2, individuals scored the highest
375 in Harm Avoidance and the lowest in Persistence (see Figure 1). In other words, individuals in
376 Joint Personality Network 1 were driven by, for example, perfectionism, optimism, and risk-
377 taking. Conversely, individuals in Joint Personality Network 2 were driven by, for example,
378 pessimism, fear, shyness, pragmatism, and underachievement.

379 ***Differences in Temperament and Character Dimensions between Individuals with Distinct Joint***

380 ***Personality (Temperament-Character) Networks***

381 The differences in personality dimensions between individuals with distinct Joint Personality
382 Networks were significant ($Wilks' \text{Lambda} = 0.76, F_{(7, 435)} = 20.03, p < .001, \text{observed power} =$
383 1.0). A Bonferroni adjustment test showed that the Joint Personality Networks differed
384 significantly with regards to all temperament and character dimensions except for Novelty Seeking
385 ($p = .045$). Reward Dependence, Persistence, Self-Directedness, Cooperativeness, and Self-
386 Transcendence were higher in the Joint Personality Network 1 compared to the Joint Personality
387 Network 2, while Harm Avoidance was higher in the Joint Personality Network 2 (see Figure 1).
388 Hence, the method (i.e., LCA) for allocating individuals to different networks depending on their
389 temperament profile and character profile seems valid. Nevertheless, we did not find a significant

390 variation regarding Novelty Seeking, most individuals scored low in this temperament trait. Hence,
391 indicating that individuals in both Joint Personality Networks are reserved, rigid, prudent with
392 their economy, and dislike disorderliness. Moreover, even though individuals in these two Joint
393 Personality Networks differed in Self-Directedness and Cooperativeness, individuals in both
394 networks scored low in Self-Transcendence. Thus, most individuals in this sample are self-
395 concerned, individualistic, skeptical, conventional, and cynical.

396 Please insert Figure 1 about here

397 ***Differences in Subjective Well-Being (Positive Affect, Negative Affect, and Life Satisfaction)***
398 ***within Individuals with Distinct Joint Personality (Temperament-Character) Networks***

399 In Joint Personality Network 1, the test of within-subject effects with Greenhouse-Geisser
400 correction was significant ($F_{(1.72, 508.60)} = 9.80, p < .001, \eta^2 p = 0.03$). The pairwise comparison with
401 Bonferroni adjustment showed that the difference between positive affect and life satisfaction was
402 not significant ($p = 1.000$)—that is, positive affect and life satisfaction were equally high. Negative
403 affect, however, was significantly lower than both positive affect and life satisfaction ($p < .001$).
404 In other words, confirming that individuals in Joint Personality Network 1 experienced positive
405 emotions more frequently and were more satisfied with their life in relation to their own experience
406 of negative emotions (see Figure 2).

407 Regarding Joint Personality Network 2, the test within subject effects with Greenhouse-
408 Geisser correction was also significant ($F_{(1.72, 287.26)} = 17.28, p < .001, \eta^2 p = 0.11$). Again, there
409 was no difference between positive affect and life satisfaction ($p = 1.000$)—that is, positive affect
410 and life satisfaction were equally low. However, a Bonferroni post hoc adjustment test indicated
411 that in contrast to the differences within the Joint Personality Network 1, negative affect was
412 significantly higher than both positive affect and life satisfaction ($p < .001$) within individuals with

413 the Joint Personality Network 2. Hence, confirming that individuals in Joint Personality Network
414 2 experienced negative emotions more frequently in relation to their own experience of positive
415 emotions and evaluations of life satisfaction (see Figure 2).

416 ***Differences in Subjective Well-Being (Positive Affect, Negative Affect, and Life Satisfaction)***
417 ***between Individuals with Distinct Joint Personality (Temperament-Character) Networks***

418 The last one-way MANOVA showed that there were significant differences between individuals
419 with distinct Joint Personality Networks ($Wilks' Lambda = 0.90$, $F_{(3, 439)} = 15.76$, $p < .001$, $\eta^2 p =$
420 0.10). The test between-subject effects indicated that the differences in life satisfaction, positive
421 affect, and negative affect between individuals in Joint Personality Networks 1 and 2 were
422 significant ($p < .001$). A Bonferroni post hoc correction test showed that individuals with a Joint
423 Personality Network 1 reported higher levels of positive affect and life satisfaction ($p < .001$),
424 while individuals with a Joint Personality Network 2 reported higher levels of negative affect ($p <$
425 $.001$). See Figure 2.

426 Hence, although a stable temperament and healthy character were separately important for
427 well-being, it was clear that it was the interaction between such temperament and character
428 configuration what yielded greater levels of subjective well-being.

429 Please insert Figure 2 about here

430 **Discussion**

431 In this study we investigated the prevalence of different Temperament and Character profiles and
432 found two Joint Personality (temperament-character) Networks in our Bulgarian sample. We also
433 found differences in subjective well-being across individuals with distinctive networks. The Joint
434 Personality Networks incorporated two Temperament Profiles, Methodical (nHrp) and Reliable
435 (nhRP), and two Character Profiles, Apathetic (sct) and Organized (Sct). All individuals in the

436 Joint Personality Network 1 had a Reliable (nhRP) Temperament Profile and an Organized (SCT)
437 Character Profile. They experienced positive affect to a greater extent and were more satisfied with
438 their lives compared to individuals in Joint Personality Network 2. Within the Joint Personality
439 Network 2 individuals belonged to the following profiles: 46.8% had a Methodical (nHrp)
440 Temperament Profile, 53.2% of them had a Reliable (nhRP) Temperament Profile, 28.1% of them
441 had an Organized (SCT) Character Profile and 71.9% had an Apathetic (sct) Character Profile.
442 Compared to individuals in Joint Personality Network 1, these individuals experienced negative
443 affect to a greater extent and lower levels of positive affect and life satisfaction. Our results agree
444 with studies showing that personality combinations are distinctively associated to individual
445 differences in both affective and cognitive aspects of subjective well-being. For example, in a
446 study among middle age New Zealanders (Spittlehouse et al., 2014), individuals with Character
447 Profiles high in both or either Self-Directedness and Cooperativeness reported higher levels of
448 well-being. Thus, implying that self-directed and communal behavior, rather than self-
449 transcendent behavior, is important for our well-being. However, in this same study, it was shown
450 that self-transcendent values or practices (i.e., self-expressive values) contribute to well-being
451 when self-directed (i.e., high Self-Directedness) and communal values (i.e., high Cooperativeness)
452 are not well developed (Spittlehouse et al., 2014). In another study among university students, the
453 Creative (SCT) Character Profile was associated with the highest levels of life satisfaction,
454 whereas the Apathetic (sct) Character Profile was associated with the lowest levels of life
455 satisfaction (Park et al., 2015). Similar results have been found in Finland (Josefsson et al., 2011),
456 Israel (Cloninger & Zohar, 2011), Sweden (Schütz, Archer & Garcia, 2013), and other countries
457 (e.g., Giakoumaki et al., 2016; Wang et al., 2019).

458 For instance, a study in the Bulgarian army population led to similar results (Dimitrova et
459 al., 2015). Clinical researchers showed that individuals who were patients diagnosed with
460 personality disorders reported low Novelty Seeking, low Persistence, and high Harm Avoidance
461 (i.e., similar to the Methodical Temperament Profile in the present study) and low
462 Cooperativeness, low Self-Directedness, and high Self-Transcendence. Conversely, Self-
463 Transcendence was low in both Character Profiles we found in our study (i.e., the Apathetic Profile
464 and the Organized Profile). On the other hand, healthy military servicemen reported high Novelty
465 seeking, high Persistence, and low Harm Avoidance; which is also in contrast to our study where
466 Novelty Seeking in both Temperament Profiles was low (Dimitrova et al., 2015). Nevertheless,
467 high Novelty Seeking among healthy military recruits seems reasonable (Mommersteeg et al.,
468 2011). Moreover, healthy military servicemen reported high Self-Directedness, high
469 Cooperativeness, and low Self-Transcendence (Dimitrova et al., 2015); which is similar to the
470 Organized Character Profile in the present study. To the best of our knowledge, however, the
471 present study is the first one to investigate Joint Personality (temperament-character) Networks in
472 the Bulgarian population, rather than single traits, and one of the few overall using LPA and LCA,
473 rather than median splits or other clustering methods, to replicate past molecular studies (Zwir et
474 al., 2022). Indeed, LPA and LCA are data-driven and create profiles and networks that are relative
475 to each other, which comes closer to modeling the dynamic nature of within and between group
476 variability of individual patterns of temperament and character and their combination. What is
477 even more, in contrast to other clustering algorithms, the methods used here allow for "model-
478 based clustering" using a probabilistic model that describes data distribution—that is, in contrast
479 to the bottom-up approach of cluster analyses in which clustering is done by finding similarities
480 between cases, LPA and LCA are top-down approaches in which clustering starts with describing

481 data distribution and use a statistical model for data selection and assessment of goodness of fit
482 (Hagenaars & McCutcheon, 2009).

483 In the present study, the Bulgarian participants were classified in two Joint Personality
484 Networks that, besides Novelty Seeking and Self-Transcendence, were almost diametrically
485 different in terms of temperament and character traits. The Joint Personality Network 1 is
486 represented by a more consolidated cohort of people with a Reliable (nhRP) Temperament Profile
487 and Organized (Sct) Character Profile, which describes them as individuals with a stable
488 temperamental disposition and a more mature character. The Joint Personality Network 2 is more
489 heterogeneous as it is represented by all temperament-character configurations but the one in Joint
490 Personality Network 1 (i.e., Reliable-Organized). These findings suggest that, if individuals with
491 a Reliable (nhRP) Temperament Profile, who reported higher levels of subjective well-being
492 compared to those with a Methodical (nHrp) Temperament Profile, have an Apathetic (sct)
493 Character profile; they will still end up with low levels of subjective well-being. Accordingly, if
494 individuals with an Organized (Sct) Character Profile, who reported higher levels of subjective
495 well-being compared to those with an Apathetic (sct) Character Profile, have a Methodical (nHrp)
496 Temperament profile; they will still end up with low levels of subjective well-being. In other
497 words, although a stable temperament and a healthy character were separately important for well-
498 being, it was clear that it was the interaction between such temperament and character
499 configuration what yielded greater levels of subjective well-being in this Bulgarian sample.

500 This conclusion is important because it goes beyond what can be inferred by just studying
501 traits or specific dimensions of personality or even temperament profiles and character profiles
502 separately. Harm Avoidance for example, is a primary personality trait associated with restraint of
503 behavior (Cloninger, 1987; Láng, 2020). In our Bulgarian sample this was confirmed by a

504 significant association between high Harm avoidance and high negative affect, as well as the fact
505 that individuals with a Methodical (nHrp) Temperament Profile reported higher levels of negative
506 affect than those with a Reliable (nhRP) Temperament Profile. At first sight, this might indicate
507 that low Harm Avoidance is determinant for low negative affect. However, it might only be
508 necessary but not sufficient. After all, individuals with the configuration Reliable-Organized (i.e.,
509 Joint Personality Network 1) emerged as the ones with the lowest levels of negative affect, while
510 those with a Reliable-Apathetic configuration, despite low levels of Harm Avoidance, reported
511 higher levels of negative affect. That being said, in our study, we lacked a network representing
512 cultural creatives, that is, those with a Reliable Temperament Profile and Creative (SCT = high in
513 all character traits) Character Profile. Indeed, most of our Bulgarian population were low in Self-
514 Transcendence. It is plausible to argue that a Creative Character Profile might always help the
515 individual to regulate the emotional reactions and experiences from any type of Temperament
516 Profile. Nevertheless, the path to well-being and a resilient life depends on processes of learning,
517 development, besides the integration of character development (Cloninger & Cloninger, 2020).
518 Put in another way, we inherit the way we learn, so nature and nurture are both always important.
519 Thus, to cope with high levels in Harm Avoidance, character development is extremely important,
520 but targeting the nervous system is also necessary (see for example Cloninger et al., 2019).

521 The lack of a third Joint Personality Network, previously found in Finland, Germany, South
522 Korea, and Portugal, is in fact our most significant finding. We had reasons for expecting such
523 results. After all, our Bulgarian sample is phenomenologically relevant to the Balkan's history of
524 repeated colonization, which might have ingrained people in Bulgaria with the specific capacity
525 for balancing different and even conflicting values, that is, Balkan pluralism (Stoyanov & Fulford,
526 2021). In fact, Bulgarians seem to have strong secular-rationalist values and weak self-expressive

527 or self-transcendent values (Inglehart, 2018ab). Thus, people with a Reliable-Organized Network
528 should be the most frequent configuration whereas those with a Reliable-Creative Network should
529 be few. Furthermore, the absence of a Reliable-Creative Network is perhaps also related to the
530 authoritarian history of Bulgaria. According to Inglehart (2018a) authoritarian systems that
531 suppress self-expression and democracy tend to be individualistic and materialistic and show less
532 development of the creative self-awareness system.

533 **Limitations**

534 In the present study we only had age and gender as demographic variables, education, for example,
535 might be an important factor behind our results. Moreover, self-report scales might result in
536 consciously or unconsciously biased accounts of individuals' experiences and are also biased
537 specifically by social desirability. Nevertheless, the ability of respondents to self-assess accurately
538 is a limitation that self-report measures have in general.

539 **Conclusions**

540 Recent studies provide evidence for the relation between personality as a complex biopsychosocial
541 adaptive system and well-being. These results reveal not only how people differ from each other
542 but also how and why certain people are happier and more satisfied with their life than others. Our
543 results are also an addition to the debate of how and why different cultures might differ regarding
544 the development of these Joint Personality (temperament-character) Networks. We argue that the
545 biopsychosocial model of personality can capture the multi-dimensional complexity of subjective
546 well-being in a variety of socio-cultural contexts. Importantly, adaptive traits can be cultivated to
547 elevate one's levels of well-being (Caspi et al., 2005; Cloninger et al., 2019; Cloninger &
548 Cloninger, 2020). It is fundamental to reveal a broader spectrum and level of analysis to personality
549 in order to provide interventions for personality development as well as a culture that allows

550 individuals to strengthen their well-being by influencing their cognition, emotions, and behavior.
551 That is, a culture that supports cultural creatives (cf. Inglehart, 2008ab) and in that way supports
552 individual and social resilience.

553 **Acknowledgements**

554 We would like to thank Sofia Angelova, who assisted with the data collection.

Table 1 (on next page)

Descriptors of high and low scorers on the Temperament and Character Inventory (TCI) subscales.

Note: Adapted with permission from Anthropedia Foundation. NS = Novelty Seeking, HA = Harm Avoidance, RD = Reward Dependence, PS = Persistence, SD = Self-directedness, CO = Cooperativeness, ST = Self-Transcendence.

2 Table 1. Descriptors of high and low scorers on the Temperament and Character Inventory (TCI)
 3 subscales.

Personality Domain	TCI Scales	TCI Subscales	High Scorers	Low Scorers
TEMPERAMENT	Novelty Seeking	NS1 excitability	exploratory	reserved
		NS2 impulsivity	impulsive	rigid
		NS3 extravagance	extravagant	thrift
		NS4 disorderly	rule-breaking	orderly
	Harm Avoidance	HA1 pessimism	pessimistic	optimistic
		HA2 fearfulness	fearful	risk-taking
		HA3 shyness	shy	outgoing
		HA4 fatigability	fatigable	vigorous
	Reward Dependence	RD1 sentimentality	sentimental	objective
		RD2 openness	warm	aloof
		RD3 attachment	friendly	detached
		RD4 dependent	approval-seeking	independent
Persistence	PS1 eagerness	enthusiastic	hesitant	
	PS2 hard-working	determined	spoiled	
	PS3 ambition	ambitious	underachieving	
	PS4 perfectionism	perfectionistic	pragmatic	
CHARACTER	Self-directedness	SD1 responsibility	responsible	blaming
		SD2 purposefulness	purposeful	aimless
		SD3 resourcefulness	resourceful	helpless
		SD4 self-acceptance	unpretentious	pretentious
		SD5 self-actualizing	self-actualizing	unfulfilled
	Cooperativeness	CO1 social tolerance	tolerant	prejudiced
		CO2 empathy	empathetic	self-centered
		CO3 helpfulness	considerate	hostile
		CO4 compassion	forgiving	revengeful
		CO5 conscience	principled	opportunistic
	Self-transcendence	ST1 self-forgetfulness	engaged	self-concerned
		ST2 transpersonal identification	joyfully connected, altruistic	separate individualistic
		ST3 spiritual acceptance	faithful	skeptical
		ST4 contemplation	contemplative	conventional
		ST5 idealism	idealistic	cynical

4 Note: Adapted with permission from Anthropedia Foundation. NS = Novelty Seeking, HA = Harm
 5 Avoidance, RD = Reward Dependence, PS = Persistence, SD = Self-directedness, CO =
 6 Cooperativeness, ST = Self-Transcendence.

Table 2 (on next page)

Correlations between temperament traits, character traits, and subjective well-being constructs (i.e., positive affect, negative affect, and life satisfaction).

Note: Highlighted cells are correlations above .20, which is the recommended minimum effect size representing a practically significant effect for social science data according to Ferguson, 2009) Blue Cells: correlations between temperament and character dimensions; Green Cells: correlations between temperament and subjective well-being constructs; Yellow Cells: correlations between character and subjective well-being constructs. ** < .001.

1 Table 2. Correlations between temperament traits, character traits, and subjective well-being constructs (i.e., positive affect, negative
2 affect, and life satisfaction).

	Dimensions	NS	HA	RD	PS	SD	CO	ST	PA	NA	LS
Temperament	Novelty Seeking (NS)										
	Harm Avoidance (HA)	-.22**									
	Reward Dependence (RD)	-.02	.01								
	Persistence (PS)	-.13**	-.37**	.18**							
Character	Self-Directedness (SD)	-.22**	-.55**	.17**	.39**						
	Cooperativeness (CO)	-.21**	-.24**	.44**	.31**	.46**					
	Self-Transcendence (ST)	.10*	-.12*	.15**	.34**	-.03	.21**				
Subjective Well-Being	Positive Affect (PA)	.04	-.40**	.13**	.56**	.37**	.27**	.32**			
	Negative Affect (NA)	.01	.42**	-.03	-.15**	-.47**	-.25**	.06	.01		
	Satisfaction with Life (LS)	-.01	-.29**	.11*	.31**	.39**	.21**	.19**	.41**	-.30**	

3 Note: Highlighted cells are correlations above .20, which is the recommended minimum effect size representing a practically significant
4 effect for social science data according to Ferguson, 2009) Blue Cells: correlations between temperament and character dimensions;
5 Green Cells: correlations between temperament and subjective well-being constructs; Yellow Cells: correlations between character and
6 subjective well-being constructs. ** < .001.

Table 3(on next page)

Latent class analysis for Joint Personality (temperament-character) Networks.

Note: * = optimum values for fit indices. The model number also indicates the number of networks within each model.

1

2 Table 3. Latent class analysis for Joint Personality (temperament-character) Networks.

Model	AIC	BIC	SABIC	Entropy	VLMRT	LMRT	BLRT
1	846.638	854.825	848.478				
2	840.770*	861.237*	845.370*	0.270	.0006*	.0008*	<.0001*
3	846.770	879.518	854.130	0.737	.5131	.5131	1.0000
4	852.770	897.799	862.890	0.845*	.5017	.5017	1.0000

3 * = optimum values for fit indices. The model number also indicates the number of networks within

4 each model.

5

Table 4(on next page)

Prevalence of individuals with different Temperament Profiles and Character Profiles clustered in each of the Joint Personality (temperament-character) Networks.

Note. n = low Novelty Seeking, H = high Harm Avoidance, h = low Harm Avoidance, R = high Reward Dependence, P = high Persistence, p = low persistence, S = high Self-Directedness, s = low Self-Directedness, C = high Cooperativeness, c = low Cooperativeness, t = low Self-Transcendence.

- 1 Table 4. Prevalence of individuals with different Temperament Profiles and Character Profiles clustered in each of the Joint Personality
 2 (temperament-character) Networks.

	Profiles	Joint Personality Network 1		Joint Personality Network 2		Total
		<i>n</i>	%	<i>n</i>	%	<i>N</i> (%)
Temperament Profiles	Methodical (nHrp)	0	0%	65	46.8%	65 (14.7%)
	Reliable (nhRP)	304	100%	74	53.2%	378 (85.3%)
Total		304	100%	139	100%	443 (100%)
Character Profiles	Apathetic (sct)	0	0%	100	71.9%	100 (22.6%)
	Organized (SCt)	304	100%	39	28.1%	343 (77.4%)
Total		304	100%	139	100%	443 (100%)

- 3 Note. n = low Novelty Seeking, H = high Harm Avoidance, h = low Harm Avoidance, R = high Reward Dependence, P = high
 4 Persistence, p = low persistence, S = high Self-Directedness, s = low Self-Directedness, C = high Cooperativeness, c = low
 5 Cooperativeness, t = low Self-Transcendence.

Figure 1

Mean differences (z-scores) in temperament and character dimensions between and within Joint Personality (temperament-character) Network 1 and 2.

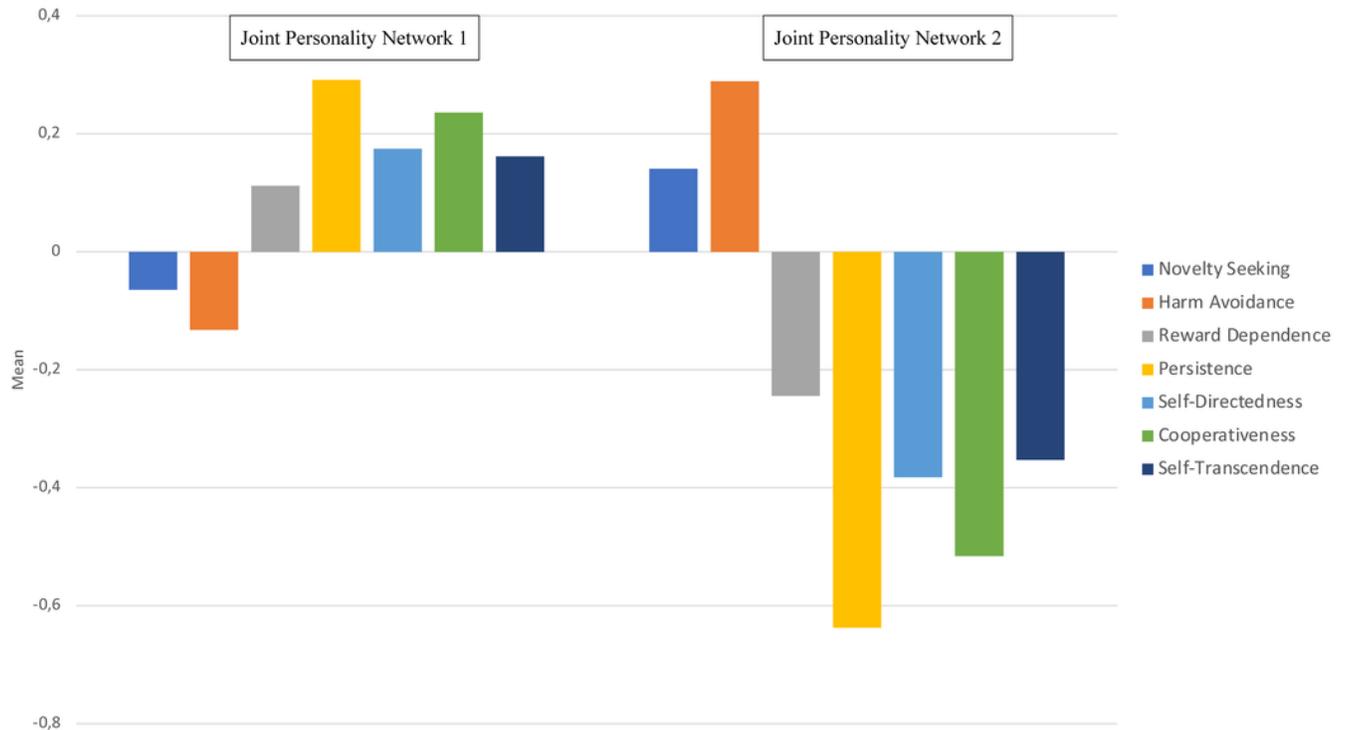

Figure 2

Mean differences (z-scores) in subjective well-being between and within Joint Personality (temperament-character) Network 1 and 2.
