Background: The problem of global aging was becoming increasingly prominent. At present, the empty nest and miniaturization of family structure reduce the function of home-based elderly care. **Methods:** A questionnaire survey was conducted on 347 elderly people in multiple communities and nursing homes in eastern coastal cities of China, and 13 institutional staff members of 8 nursing institutions that carried out the medical-nursing integration model were interviewed as the research objects. The survey mainly focuses on the basic characteristics of the elderly, the family support system, and the acceptance of medical care and health care. The influencing factors were screened by t test, univariate analysis and multivariate logistic regression analysis. SPSS software was used to test the reliability and validity of the questionnaire, and the Cronbach's was 0.792, which can be considered that the questionnaire had good internal reliability. The classification of the questionnaire was reasonable, the reliability of the questionnaire was high, and the internal consistency of the scale was high. According to KMO and Bartlett test, $KMO=0.826$, $\chi^2=853.731$, the degree of freedom was 36, and the p value was 0.000. **Results:** The proportion of male and female respondents was 48.1% and 51.9% respectively. Multivariate logistic regression analysis results showed that gender had no statistical significances on the degree of support for combine medical and health care in the elderly ($P>0.05$). The results showed that gender, age, marital status, medical insurance type and old-age insurance type had little effect on the support of the combination of medical care and health care for the elderly ($P>0.05$). Compared with the control group with education below primary school, the elderly with bachelor's degree or above are more willing to support the combination of medical care and health ($P<0.05$). The registered residence type is more obvious than that of the urban residents ($P<0.05$).

Compared with the enterprise employees in the control group, the elderly who were employed as migrant workers before retirement were more willing to support the combination of medical care and health ($P < 0.05$). From the perspective of family monthly income, the elderly with family income ≥ 10000 RMB have more obvious support for the combination of medical care and health than the elderly with family monthly income < 3000 RMB in the control group ($P < 0.05$). In terms of the degree of understanding, the degree of understanding and support in different degrees are significantly higher than that in the control group ($P < 0.05$). **Conclusion:** Through multivariate logistic regression analysis, education level, registered residence, pre-retirement occupation and family income are more obvious for the elderly to support medical care and health. it is necessary to increase investment in elderly activity centers, actively carry out activities.

30 **Abstract**

31 **Background:** The problem of global aging was becoming increasingly prominent. At present, the
32 empty nest and miniaturization of family structure reduce the function of home-based elderly care.

33 **Methods:** A questionnaire survey was conducted on 347 elderly people in multiple communities

34 and nursing homes in eastern coastal cities of China, and 13 institutional staff members of 8
35 nursing institutions that carried out the medical-nursing integration model were interviewed as the
36 research objects. The survey mainly focuses on the basic characteristics of the elderly, the family
37 support system, and the acceptance of medical care and health care. The influencing factors were
38 screened by t test, univariate analysis and multivariate logistic regression analysis. SPSS software
39 was used to test the reliability and validity of the questionnaire, and the Crobach's was 0.792,
40 which can be considered that the questionnaire had good internal reliability. The classification of
41 the questionnaire was reasonable, the reliability of the questionnaire was high, and the internal
42 consistency of the scale was high. According to KMO and Bartlett test, $KMO=0.826$, $\chi^2=853.731$,
43 the degree of freedom was 36, and the p value was 0.000.

44 **Results:** The proportion of male and female respondents was 48.1% and 51.9% respectively.
45 Multivariate logistic regression analysis results showed that gender had no statistical significances
46 on the degree of support for combine medical and health care in the elderly ($P>0.05$). The results
47 showed that gender, age, marital status, medical insurance type and old-age insurance type had
48 little effect on the support of the combination of medical care and health care for the elderly
49 ($P>0.05$). Compared with the control group with education below primary school, the elderly with
50 bachelor's degree or above are more willing to support the combination of medical care and health
51 ($P<0.05$). The registered residence type is more obvious than that of the urban residents ($P<0.05$).
52 Compared with the enterprise employees in the control group, the elderly who were employed as
53 migrant workers before retirement were more willing to support the combination of medical care

54 and health ($P < 0.05$). From the perspective of family monthly income, the elderly with family
55 income ≥ 10000 RMB have more obvious support for the combination of medical care and health
56 than the elderly with family monthly income < 3000 RMB in the control group ($P < 0.05$). In terms
57 of the degree of understanding, the degree of understanding and support in different degrees are
58 significantly higher than that in the control group ($P < 0.05$).

59 **Conclusion:** Through multivariate logistic regression analysis, education level, registered
60 residence, pre-retirement occupation and family income are more obvious for the elderly to support
61 medical care and health. It is necessary to increase investment in elderly activity centers, actively
62 carry out activities.

63 **Key words:** Medical and health care; willingness; family support; elderly people; related factors.

64 **Introduction**

65 At present, the problem of global aging was becoming more and more prominent, and our country
66 was also in a period of rapid development of population aging. Up to November 2020, there were
67 approximately 264 million people over 60 years old in my country, accounting for 18.7% of the
68 total population. It is estimated that by 2025, the number of elderly people aged 65 and above in
69 China will reach 200 million, and the aging of China's population is deepening, and the trend will
70 be irreversible (J. Han, 2022; None, 2021). At present, indicators such as average life expectancy
71 and mortality are still an important basis for measuring health status in China (Kang et al., 2021;
72 Si et al., 2021). With the aging and disability of the population becoming more and more

73 prominent, it is still extremely challenging to meet the needs of elderly care services and medical
74 care, increase the life expectancy of the population, reduce the mortality rate, and promote national
75 health. The traditional community-based home-based elderly care and most elderly care
76 institutions are mainly based on life care, lack of one-stop medical care and health care services,
77 and cannot fully meet the medical service needs of the elderly. Under this premise, the elderly
78 have increased demand for medical care and health care, and the governments of coastal cities in
79 eastern China are also demand-oriented, and actively promote the construction of integrated
80 medical care and health care projects such as home care, community care, and day care.

81 "Medical" includes outpatient services and rehabilitation physiotherapy, "Health care" includes
82 daily care and emotional support (Zhang, Wang, Jin, & Jiang, 2017). Combine medical and health
83 care advocates the early intervention and integration of medical resources into elderly care
84 services, so as to meet the needs of elderly care services and medical services for the elderly, while
85 promoting national health. However, the implementation of the integration project of medical care
86 and health is affected by the government level and the personal will of the elderly (B. Wang, Liu,
87 Zheng, Wang, & Zhang, 2021; C. Wang et al., 2022). At the government level, the smooth
88 connection between medical and health care and elderly care services is insufficient, the quality of
89 medical care and elderly care services needs to be improved, and relevant economic and technical
90 policy support needs to be improved, which affect the construction of combine medical and health
91 care projects. In terms of personal wishes, the elderly are more likely to choose home care.
92 However, the empty nest and miniaturization of the current family structure reduces the function

93 of home care; at the same time, the increase in the family structure of "4-2-1", "4-2-2" and even
94 "4-2-3" caused by the birth policy has caused certain obstacles to the advancement of combine
95 medical and health care (L. Liu, Chen, Ying, & Leng, 2019). Therefore, we aimed to study elderly
96 people's willingness to combine medical and health care and related factors in coastal cities in
97 eastern China and to analyze the relevant factors, in order to build a local integrated service
98 innovation model of combine medical and health care, which are suitable for the social conditions
99 and strategic and institutional background of coastal cities in eastern China.

100 **Objects and Methods**

101 **Research object**

102 This research was based on 2 typical communities and 8 nursing homes in eastern coastal cities in
103 China, one of the first batch of 50 "national pilot units for the combination of medical care and
104 maintenance" were used as research carriers. A total of 354 questionnaires were distributed, and
105 347 were actually recovered, with a recovery rate of 98.0%. Inclusion criteria: ① age \geq 60 years;
106 ② Be aware and able to complete the questionnaire independently or with the assistance of others;
107 ③ Residence in eastern coastal cities in China \geq 1 year.

108 **Ethical statement**

109 This study was approved by the Ethics Committee of Zhejiang Hospital (2020, No. 115 and 2021,
110 No 75k), and all elderly people had signed informed consent forms.

111 **Research methods**

112 In June 2021, through a large number of literature review, a questionnaire was formulated for the
113 medical care of the willingness and influencing factors of the elderly in Eastern coastal cities in
114 China. With the strong support of the school of Humanities and management of Zhejiang Chinese
115 Medical University a college student practice group was established to investigate this theme.
116 Before this investigation, the members of the research group shall conduct unified training for the
117 members of the practice group to ensure that the members of the practice group use unified
118 guidelines. The survey was conducted in some communities and nursing homes in Eastern coastal
119 cities in China by convenient sampling. The survey was conducted by questionnaire and written
120 questionnaire. For the elderly who can independently operate the mobile phone questionnaire star,
121 the questionnaire star method was adopted for the survey. For the elderly who cannot use the
122 mobile phone to answer, the members of the practice group conducted the survey in the form of
123 question and answer.

124 **Research tools**

125 This study followed the relevant spirit of the State Council's "guiding opinions on promoting the
126 combination of medical and health care and elderly care services" (Y. Han & Li, 2018) and
127 "Hangzhou measures for promoting the integration of medical and health care and intelligent
128 medical services" (None, 2015). Referring to the ADL self-care theory, the members of the
129 research group compiled a questionnaire on the willingness of the elderly in Eastern coastal cities
130 in China to combine medical care and health and related factors. The questionnaire survey included
131 general information, mental health, physical status, family support system, acceptance of the

132 integration of medical care and health, etc. The preparation process of the questionnaire was as
133 follows: Through a large number of literature review, the interview outline of the influencing
134 factors of medical maintenance and health was formulated. Eight elderly people were interviewed
135 in the Second Affiliated Hospital of Zhejiang Chinese Medical University and Zhejiang hospital
136 to collect the core information of the elderly about medical care and health. Through SPSS
137 software to test the reliability and validity of the questionnaire, it is concluded that Crobach's was
138 0.792, which can be considered that the questionnaire had good internal reliability. The
139 classification of the questionnaire was reasonable, the reliability of the questionnaire was high,
140 and the internal consistency of the scale was high. According to KMO and Bartlett test,
141 $KMO=0.826$, $\chi^2=853.731$, the degree of freedom was 36, and the p value was 0.000. It showed
142 that the correlation between various factors was very strong, and the results were scientific and
143 reliable.

144 **Quality Control**

145 In July 2021, with the support of the School of Humanities and Management of Zhejiang
146 University of Traditional Chinese Medicine, a college student practice group named "Beautiful
147 Zhejiang Practice Group" was established to conduct research on this theme. Before the official
148 start of the research, the members of the practice group conduct unified training to ensure that the
149 members of the practice group use unified guidelines to explain the research purpose and filling
150 method to the research subjects when collecting data, so as to gain the trust and cooperation of the
151 research subjects. During the investigation, all questionnaires and interviews were conducted

152 independently and anonymously, without involving the personal privacy of the respondents and
153 the interviewees, and the true thoughts of the respondents were collected as much as possible.
154 During the data entry process, data checkers repeatedly analyze and proofread the data to ensure
155 the accuracy and reliability of the data.

156 **Pilot scale study**

157 Before the formal investigation, a representative community in the coastal cities and municipalities
158 in eastern China that has developed a model of combining medical care, nursing and health care -
159 Fuyang Ruifeng Senior Apartment Community, and two elderly hospitals - Zhejiang Hospital and
160 Xihu District Integrated Traditional Chinese and Western Medicine Hospital were selected. A 3-
161 day pre-survey was conducted among 90 senior citizens. At the same time, 13 institutional staff
162 members from 4 elderly care institutions of different levels and types were selected for interviews,
163 considering the heterogeneity factors such as geographical location and scale. According to the
164 results of the pre-investigation and the interview content of the staff, the content of the
165 questionnaire was modified and deleted, and the structure was adjusted so that the elderly could
166 better understand the questions and answer them independently.

167 **Sample size calculation**

168 This survey uses convenience sampling to select 2 typical communities and 8 nursing homes in
169 eastern coastal cities and cities in China, one of the first batch of 50 "national pilot units for the
170 combination of medical care and maintenance", as research carriers. In order to obtain higher

171 accuracy, the confidence level was determined as 95% ($=1.962$), the maximum allowable absolute
172 error was 8% ($\mu=0.08$). According to the maximum value of $P=0.5$, the initial sample size was
173 determined as 286, and 354 questionnaires were actually recovered. 347 copies, with a recovery
174 rate of 98.0%. To ensure the accuracy of the data, the investigators uploaded the survey data in
175 real time on the terminal.

176 **Statistical analysis**

177 The data set was established with Excel 2017 and imported into SPSS 21.0 software package for
178 statistical analysis. The frequency, composition ratio and are used for statistical description. T-test,
179 one-way ANOVA and multiple linear regression analysis were used to analyze the influencing
180 factors of family medical maintenance integrated service demand. The difference was statistically
181 significant ($P < 0.05$).

182 **Results**

183 **Basic Patient Information**

184 According to the purpose and object of the survey, the basic information of the surveyed elderly,
185 such as gender, age, education level, marital status, medical insurance, pension insurance type and
186 monthly family income, were analyzed as follows (**Figure 1**). 48.1% of men and 51.9% of women
187 participated in the questionnaire. Among them, 37.5% were aged 60-65, 13.3% were aged 66-70,
188 15.6% were aged 71-75, 9.5% were aged 76-80 and 24.2% were aged over 80. The number of
189 people with education level of primary school and below accounted for 27.7%, that of junior high

190 school and senior high school accounted for 41.8%, and that of college and above accounted for
191 30.6%. 76.9% were married, 2% were unmarried, 17.6% were widowed and 3.5% were divorced.
192 The number of people without medical insurance accounted for 6.6%, and the number of people
193 with commercial medical insurance accounted for 9.8%. The new rural cooperative insurance
194 accounted for 21%, the medical insurance for urban residents accounted for 14.1% and the medical
195 insurance for urban employees accounted for 42.7%. Both commercial insurance and medical
196 insurance accounted for 5.8%. The number of people without endowment insurance accounted for
197 15.3%, the number of people whose endowment insurance was government organs and institutions
198 accounted for 33.7%, urban employees or urban and rural residents account for 36%, land
199 expropriated farmers accounted for 7.5%, and commercial insurance accounted for 7.5%. 13.3%
200 of households have a monthly income of less than 3000 RMB, 25.1% have a monthly income of
201 3000-5999 RMB, 31.7% have a monthly income of 6000-9999 RMB, and 30% have a monthly
202 income of 10000 RMB or more.

203 **Residents' cognition of the combination of medical and health care**

204 Residents have a high level of awareness of the combination of medical care and health. Well
205 known, know and better known (63.4%), little known and unknown (35.6%). The cognitive level
206 of residents aged 60-80 was more than 60%, and the cognitive level of residents over 80 was lower
207 than that of other age groups ($\chi^2=43.925$, $P<0.05$). The higher the education level of the elderly,
208 the higher the recognition of the medical and health care ($\chi^2=65.490$, $P<0.05$). Registered
209 residence type, urban residents' awareness of medical and health care combination was higher than

210 that of suburban residents ($\chi^2=28.331$, $P<0.05$). The overall cognitive level of married residents
211 was significantly higher than that of residents with other marital status ($\chi^2=32.027$, $P<0.05$).
212 Residents whose occupation before retirement was enterprise employees and national civil
213 servants have higher cognition ($\chi^2=51.861$, $P<0.05$). Residents whose medical insurance was
214 commercial insurance or commercial insurance and medical insurance have higher overall
215 cognition than residents with other medical insurance ($\chi^2=64.252$, $P<0.05$). Residents without
216 pension insurance have higher awareness than other residents ($\chi^2=27.857$, $P<0.05$). The higher
217 the monthly family income, the higher the residents' cognition ($\chi^2=43.312$, $P<0.05$) (**Table 1**).

218 **Family situation**

219 Residents' overall support for the combination of medical and health care was relatively high. The
220 family monthly income was higher, the residents' support for the combination of medical and
221 health care was higher. The residents willing to spend 1000-1999 RMB and ≥ 4000 RMB per
222 month for the combination of medical and health care have a higher degree of support than other
223 spending levels. In the survey, 7 elderly people have no children. After excluding 7 the elderly,
224 the data showed that 98.5% of their children support, support and very much support the
225 combination of medical care and health. The higher level of support of children, the higher level
226 of support of the elderly (**Table 2**).

227 **Willingness to combine medical care with health care**

228 More than 95% of the elderly and their children supported the combination of medical and health

229 care. In the survey, the higher the understanding of the combination of medical and health care,
230 the higher the degree of support ($\chi^2=49.694$, $P<0.05$) (**Table 3, Figure 2**).

231 **Multivariate logistic regression analysis**

232 Based on the χ^2 test, this study combined with multivariate ordered logistic regression analysis.
233 To explore the influence of various factors on the willingness of the elderly to combine medical
234 and health care in Eastern coastal cities in China, a multi-factor ordered logistic regression analysis
235 was carried out on 347 cases. The results showed that gender, age, marital status, medical insurance
236 type and old-age insurance type had little effect on the support of the combination of medical and
237 health care for the elderly ($P>0.05$). In terms of educational level, compared with the control group
238 with education below primary school, the elderly with bachelor's degree or above are more willing
239 to support the combination of medical and health care ($P<0.05$). The registered residence type was
240 more obvious than that of the urban residents ($P<0.05$). In terms of occupation, compared with the
241 enterprise employees in the control group, the elderly who were employed as migrant workers
242 before retirement were more willing to support the combination of medical and health care
243 ($P<0.05$). From the perspective of family monthly income, the elderly with family income ≥ 10000
244 RMB have more obvious support for the combination of medical and health care than the elderly
245 with family monthly income < 3000 RMB in the control group ($P<0.05$). In terms of the degree of
246 understanding, the degree of understanding and support in different degrees are significantly
247 higher than that in the control group ($P<0.05$) (**Table 4**).

248 **Discussion**

249 **The current situation of China's national conditions**

250 At present, China is in the rapid development stage of population aging. The aging problem was
251 serious and causes social anxiety. The elderly have no home and nowhere to go. The disabled and
252 retarded elderly stay in medical institutions and consume medical resources. However, more and
253 more elderly people are afraid of getting old because they can't get effective care or the cost of
254 care was too high. Medical and health care will provide full-cycle continuous health management
255 and care for the healthy elderly, high-risk elderly, semi-disabled and disabled elderly in different
256 service scenarios. At present, the state has vigorously advocated the combination of medical and
257 health care at the policy level, and encouraged the provision of one-stop medical and health care
258 services for the elderly (Tan, 2019; Zeng & Liu, 2016). The outline of "healthy China 2030" plan
259 clearly proposes to "focus on the whole population and the whole life cycle" and improve the
260 "treatment rehabilitation long-term care service chain".

261 **Analysis of willingness to combine medical and health care and related factors**

262 Whether the policy was implemented in place, in addition to the strong support of government
263 departments was related to the willingness of the elderly to combine medical and health care and
264 related factors. In this study, the willingness to combine medical and health care and related factors
265 was studied in Eastern coastal cities in China. It provides a basis for effectively establishing a
266 medical and health care service system in line with Eastern coastal cities in China and establishing
267 a practical, effective and landing integrated medical care service model. From the single factor
268 analysis of Table 1, we can see that the level of education, pre-retirement occupation, registered

269 residence type and family monthly income affect the cognition level of the elderly to medical and
270 healthy care. And this was consistent with the conclusions of Wu Li group (Jiang, Dong, & Li,
271 2020; Wu, Yao, Li, He, & Xie, 2020). The reason for the analysis was that for this group with high
272 education level, their pre-retirement career will be relatively stable and their family monthly
273 income will be higher. Such groups will also pay more attention to which medical care method
274 was more suitable for themselves. This was also confirmed by the family situation and degree of
275 support in Table 2: the family monthly income was positively correlated with the degree of support
276 for the combination mode of medical and health care, which was also confirmed by the research
277 of Liu Jinlin (J. Liu, Shen, & Chen, 2018). It showed that the elderly's support for medical and
278 health care services was restricted by their economic ability. Their family income was high, and
279 they have a higher ability to bear and pay for medical care and health. The income level was usually
280 positively correlated with the education level. The elderly with higher education level will timely
281 evaluate their health needs and respond positively (Zhuang, Jiang, & Zhang, 2016). The study
282 found that the elderly with registered residence as urban residents were more familiar with the
283 medical maintenance mode while the suburban residents knew less. The reason was that the
284 medical care market in the urban area has developed rapidly and the information has been obtained
285 more thoroughly. On the other hand, affected by the baby boom in the 1960s and the family
286 planning policy in the 1980s, the family aging structure has developed abruptly. In the face of the
287 care work of four elderly people, urban residents with limited accompanying care energy more
288 choose to support the medical care model, and the elderly were also affected by the surrounding
289 population. Due to the pressure of public opinion, more children still chose family pension.

290 Therefore, suburban farmers have limited sources of information on the combination of medical
291 and health care. The degree of children's support for the medical care model affected the elderly's
292 cognition and support for the medical care model, which was consistent with the research
293 conclusions of Liu Liyun et al.(L. Liu et al., 2019).

294 Through multivariate logistic regression analysis, from the perspective of educational level,
295 compared with the control group with education below primary school, the elderly with bachelor
296 degree or above are more willing to support the combination of medical care and health care. The
297 registered residence type was more obvious than that of the urban residents. In terms of occupation,
298 compared with the enterprise employees in the control group, the elderly who were employed as
299 migrant workers before retirement were more willing to support the combination of medical care
300 and health. From the perspective of family monthly income, the elderly with family income \geq
301 10000 RMB have more obvious support for the combination of medical care and health than the
302 elderly with family monthly income < 3000 RMB in the control group. In terms of the degree of
303 understanding, the degree of understanding and support in different degrees are significantly
304 higher than that in the control group.

305 **Highlights and Shortcomings**

306 In this study, with the help of a typical community health service center, one of the first batch of
307 50 "national pilot units for the combination of medical care and maintenance" as a carrier, we have
308 an in-depth understanding of the development of combine medical and health care. However, in
309 this study, although 347 valid samples were successfully obtained, which is representative in the

310 eastern coastal cities of China, the sample size still needs to be expanded if it is extended to the
311 whole country. In the future research, information technology can be effectively used to expand
312 the sample size through non-contact methods such as emails and text messages. In addition, there
313 is a bias in the survey of the elderly with dialects. Although the staff will follow the explanation
314 during the survey, the staff will have a certain inductiveness to the elderly, and there may be a
315 certain bias in the results.

316 **Suggestions**

317 Increase investment in elderly activity centers, and actively carry out elderly activities that were
318 beneficial to physical and mental health. Learning health care knowledge, providing healthy diet
319 and spiritual comfort to alleviate the pressure of family and social elderly care, this was an
320 important way to achieve healthy elderly care and healthy aging. It was also necessary to
321 strengthen the training of professional talents and improve the level of elderly care in communities
322 or institutions. The government and elderly care institutions should do a good job in the planning
323 and construction of institutional elderly care in accordance with the demographic characteristics
324 of the local elderly and the development level of elderly care services. And build a group of new
325 elderly care institutions and fully functional elderly care institutions with medical care, elderly
326 care, nursing care, rehabilitation and end-of-life escort. And strengthen the training of
327 professionals with a combination of medical care and nursing, improve the level of institutional
328 care for the elderly, provide convenient and high-quality medical, rescue, rehabilitation, care,
329 comfort and other services for the elderly, sickly, and disabled elderly, and provide satisfactory

330 material and spiritual services.

331 **Conclusion**

332 In this study, the willingness and related factors of the combine medical and health care were
333 studied in the eastern coastal cities of China, in order to effectively establish a localized combine
334 medical and health care in line with the social conditions, strategies and institutional background
335 of the eastern coastal cities in China. It provides a basis for meeting the dual needs of the elderly
336 for medical care and old-age care.

337 Based on the results of this study, we believe that it is necessary to increase investment in elderly
338 activity centers, actively carry out activities that are beneficial to the physical and mental health of
339 the elderly, and improve the level of elderly care in communities and institutions. The government
340 and elderly care institutions should establish fully functional elderly care institutions such as
341 medical care, elderly care, nursing, rehabilitation, and hospice care. To sum up, it is necessary to
342 improve the service level of elderly care institutions, provide the elderly with convenient and high-
343 quality medical, rescue, rehabilitation, nursing, comfort and other services, and provide
344 satisfactory material and spiritual services.
