**Abstract Background.** Bell's Palsy is an idiopathic facial nerve dysfunction causing temporary paralysis of muscles of facial expression. This study aimed to determine the incidence, common risk factors, and preferred treatment by the Saudi patients with Bell's Palsy. **Method.** This cross-sectional study was carried out in the Qurayyat region of Saudi Arabia. The retrospective medical records were searched from 2015-2020 of patients diagnosed with Bell's Palsy at Qurayyat General Hospital and King Fahad hospital. A 28-item questionnaire was developed by a team of experts and pre-tested among patients with Bell's Palsy before being sent to the eligible participants. The data was analyzed using summary statistics, Chi-square test, Fisher exact test and Likelihood ratio test. **Results.** We identified 279 cases of Bell's Palsy from the medical records of the hospitals from the years 2015 to 2020, accounting for 46.5 cases per year and an incidence of 25.7 per 100,000 per year. Out of 279 patients with Bell's Palsy, only 171 returned the questionnaire accounting for a response rate of 61.2%. Out of 171 patients with Bell's Palsy, females (n=147, 86.0%) accounted for the majority of cases. The most affected age group among participants with Bell's Palsy was 21-30 years (n = 76, 44.4%). There were 153 (89.5%) cases who reported Bell's Palsy for the first time. The majority of the participants experienced right-sided facial paralysis (n = 96, 56.1%). Likelihood ratio test revealed significant relationship between exposure to cold air and common cold with age groups ( $\chi^2(6, N = 171) = 14.926, P = 0.021$ ),  $\chi^2(6, N = 171) = 16.354, P = 0.012$  respectively. The post hoc analyses revealed that participants in the age group of 20-31-years were mostly affected due to exposure to cold air and common cold than the other age groups. The main therapeutic approach preferred was physiotherapy (n=149, 87.1 %), followed by corticosteroids and antivirals medications (n=61, 35.7%), acupuncture (n=35, 20.5%), traditional Saudi herb medicine (n=32, 18.7%), cauterization by hot iron rod

(n=23, 13.5%), supplementary therapy (n=2, 1.2%), facial cosmetic surgery (n=1, 0.6%) and no treatment (n=1, 0.6%). The most preferred combined therapy was physiotherapy (87.6%) with corticosteroid and antiviral drugs (35.9%), and acupuncture (17.6%).

**Conclusion.** The rate of Bell's Palsy was approximately 25.7 per 100,000 per year in the Qurayyat region of Saudi Arabia. Exposure to cold air and common cold were the significant risk factors associated with Bell's Palsy. Females were predominantly affected by Bell's Palsy in the Qurayyat region of Saudi Arabia. Bell's Palsy most commonly occurred in the age group 21-30 years . The most favored treatment was physiotherapy following Bell's Palsy.

17

## 18 Abstract

19 **Background.** Bell's Palsy is an idiopathic facial nerve dysfunction causing temporary paralysis  
20 of muscles of facial expression. This study aimed to determine the incidence, common risk  
21 factors, and preferred treatment by the Saudi patients with Bell's Palsy.

22 **Method.** This cross-sectional study was carried out in the Qurayyat region of Saudi Arabia. The  
23 retrospective medical records were searched from 2015-2020 of patients diagnosed with Bell's  
24 Palsy at Qurayyat General Hospital and King Fahad hospital. A 28-item questionnaire was  
25 developed by a team of experts and pre-tested among patients with Bell's Palsy before being sent  
26 to the eligible participants. The data was analyzed using summary statistics, Chi-square test,  
27 Fisher exact test and Likelihood ratio test.

28 **Results.** We identified 279 cases of Bell's Palsy from the medical records of the hospitals from  
29 the years 2015 to 2020, accounting for 46.5 cases per year and an incidence of 25.7 per 100,000  
30 per year. Out of 279 patients with Bell's Palsy, only 171 returned the questionnaire accounting  
31 for a response rate of 61.2%. Out of 171 patients with Bell's Palsy, females (n=147, 86.0%)  
32 accounted for the majority of cases. The most affected age group among participants with Bell's  
33 Palsy was 21–30 years (n = 76, 44.4%). There were 153 (89.5%) cases who reported Bell's Palsy  
34 for the first time. The majority of the participants experienced right-sided facial paralysis (n =  
35 96, 56.1%). Likelihood ratio test revealed significant relationship between exposure to cold air  
36 and common cold with age groups ( $\chi^2(6, N = 171) = 14.926, P = 0.021$ ),  $\chi^2(6, N = 171) =$   
37  $16.354, P = 0.012$  respectively. The post hoc analyses revealed that participants in the age group  
38 of 20-31-years were mostly affected due to exposure to cold air and common cold than the other  
39 age groups.

40 The main therapeutic approach preferred was physiotherapy (n=149, 87.1 %), followed by  
41 corticosteroids and antiviral medications (n=61, 35.7%), acupressure (n=35, 20.5%), traditional  
42 Saudi herb medicine (n=32, 18.7%), cauterization by hot iron rod (n=23, 13.5%), supplementary  
43 therapy (n=2, 1.2%), facial cosmetic surgery (n=1, 0.6%) and no treatment (n=1, 0.6%). The  
44 most preferred combined therapy was physiotherapy (87.6%) with corticosteroid and antiviral  
45 drugs (35.9%), and acupressure (17.6%).

46 **Conclusion.** The rate of Bell's Palsy was approximately 25.7 per 100,000 per year in the  
47 Qurayyat region of Saudi Arabia. Exposure to cold air and common cold were the significant risk  
48 factors associated with Bell's Palsy. Females were predominantly affected by Bell's Palsy in the  
49 Qurayyat region of Saudi Arabia. Bell's Palsy most commonly occurred in the age group 21-30  
50 years. The most favored treatment was physiotherapy following Bell's Palsy.

51

52 Keywords: Bell's Palsy; Facial Palsy; risk factors; physiotherapy; cross sectional survey;  
53 incidence; prevalence.

54

## 55 Introduction

56 Bell's Palsy is a common lower motor nerve paralysis of facial nerve of unknown origin (Eviston  
57 et al.). The patient with Bell's Palsy experiences sudden unilateral flaccid paralysis of muscles of  
58 facial expression, rarely bilateral (Gilden). The patient is unable to perform facial movements on  
59 the affected side and facial asymmetry becomes clear with attempted facial movements (Reich).  
60 The annual incidence (1992-1996) has been reported 20.2 per 100,000 populations as per the UK  
61 General Practice Research database (Rowlands et al.). Research studies globally report variation  
62 in annual incidence (11-50 cases per 100,000) of Bell's Palsy (Monini et al.; Ji et al.; Hsieh et  
63 al.; Kokotis and Katsavos; Yilmaz et al.). The national prevalence of Bell's Palsy in Saudi  
64 Arabia is unknown, however, regional incidence/prevalence was reported in a few studies such  
65 as 5.35 per 100,000 per year (1992-1995) incidence in the Asir region (Al Ghamdi), 30.4%  
66 cases of Bell's Palsy per 100,000 per year (1995-1997) in the Qassim region (Hamid), 26.3-  
67 27.8 % cases per 100,000 per year (2011-2012) in the Aljouf region (Jamil et al.), and 26.3 %  
68 cases per 100,000 per year (2016-2017) in the Arar region (Alanazi et al.).

69 The cause of Bell's Palsy is idiopathic; however many possible causes have been recognized  
70 such as reactivation of the herpes simplex virus, human immunodeficiency virus, and hepatitis C  
71 virus (Greco et al.). Additionally, there are several risk factors associated with Bell's Palsy such  
72 as age, pregnancy, epilepsy, obesity, hypertension, diabetes, respiratory tract infection,  
73 vaccination (Colella et al.) (Potterton), and genetic susceptibility due to consanguineous  
74 marriages in Saudi Arabia (Middle et al.). A recent increase in the prevalence of diabetes  
75 (Elhadd et al.), hypertension (Al-Nozha, Abdullah, et al.), and obesity (Al-Nozha, Al-Mazrou, et  
76 al.) in Saudi Arabia increase the risk of Bell's Palsy. Moreover, a customary practice of  
77 consanguineous marriages increases the risk of autosomal recessive genetic disorders  
78 (AbdulAzeez et al.). Therefore, a study is needed to explore the possible impact of increased risk  
79 factors and consanguineous marriage on the incidence of Bell's palsy in Saudi population.

80 A standard recommended treatment of Bell's Palsy includes oral corticosteroids and limited  
81 evidence about the additive benefit of antiviral drugs for 10-12 days (Allen and Dunn; Salinas et  
82 al.; Engström et al.; Heckmann et al.) , additionally, physiotherapy modalities (Gatidou et al.),  
83 acupuncture (Bae), dry needling (Zhang et al.), taping (Ghous et al.), and neural mobilization  
84 technique (Kashoo et al.) has been reported to be beneficial. However, the traditional method to  
85 treat Bell's Palsy in Saudi Arabia is still in practice. Some of the common traditional methods for  
86 general pain management is using herbs (Shaikh) and cauterization (Aboushanab and AlSanad).  
87 Cauterization for Bell's Palsy is performed by placing a hot iron rod at the back of the neck  
88 region or between the thumb and index finger (Alsanad et al.). Such traditional methods may  
89 result in severe burn injuries and sometimes develop into complicated wounds in cases with pre-  
90 existing conditions such as diabetes (Qureshi et al.).  
91 There is limited literature about the contribution of risk factors and treatment preferred by the  
92 Saudi population following diagnosis of Bell's Palsy. Therefore, the aim of this study is to  
93 determine the incidence, possible risk factors, and preferred treatment options following Bell's  
94 palsy in the Saudi population.

## 95 **Materials & Methods**

96 **Study design and settings:** The study is a retrospective cross-sectional hospital-based study.  
97 The study was carried out in the department of physiotherapy at the Qurayyat General Hospital  
98 and King Fahad hospital. Ethical approval was obtained from the ethical committee of the  
99 hospitals in December 2020 prior to the commencement of the study(QGH-EC-16-2020).  
100 The files and medical records of patients diagnosed with Bell's Palsy were reviewed in Qurayyat  
101 General Hospital and King Fahad Hospital. Two hundred seventy-nine patients from the years  
102 2015 to 2020 (inclusive) were identified and contacted through email and telephone for  
103 participation. Where the patient was a minor, parents were contacted for consent (Figure 1). The  
104 subjects were included in the study if they were diagnosed with Bell's Palsy by a qualified  
105 medical doctor. One subject who was recruited through community advertisement was assessed  
106 by a neurologist at the Qurayyat general hospital.

107 **Study Method:** The retrospective medical records of two major hospitals (Qurayyat General  
108 hospital and King Fahad hospital) were searched for patients diagnosed with Bell's Palsy. The  
109 eligible patients were communicated through SMS, telephone, and email. The advertisement to  
110 participate in the study was made across the hospital and in community centers such as shopping  
111 centers in the form of pamphlets. All eligible participants were invited to participate in the study.  
112 Those who consented were requested to fill out an online questionnaire consisting of 28  
113 questions. Non-respondents were contacted again after an interval of two weeks for a maximum  
114 of four times till all communications were stopped.

## 115 **Questionnaire**

116 A group of experts consisted of four clinicians (two neurologists, two general physicians) and  
117 four academic university staff (one associate professor in physiotherapy, one language expert,  
118 two professors in medical college) with an average experience of more than 10 years. A  
119 preliminary set of questions were submitted by the authors of this study to the expert committee.

120 The preliminary sets of questions were emailed to every member of the expert committee before  
121 the meeting. The expert committee conducted two meetings before finalizing a set of 28-  
122 questions (Appendix 1).

123 The questionnaire was pre-tested among 10 Bell's Palsy patients visiting Qurayyat general  
124 hospital for clarity. Any question that was indicated unclear by patients was rephrased by the  
125 expert committee until all expert members approved the changes.

126 The final version of the questionnaire was piloted among 30 patients with Bell's Palsy visiting  
127 Qurayyat general hospital and King Fahad hospital. The internal consistency of the 28 item  
128 questionnaire was 0.716 calculated by Cronbach's alpha.

### 129 **Sample size calculation**

130 The target population was Bell's Palsy patients in the Qurayyat region of Saudi Arabia. For  
131 sample size calculation, the sample size from reviewing medical records was 279. To achieve a  
132 95% Confidence interval with a 5% margin of error and 50% response distribution, the current  
133 study required 162 Bell's Palsy patients to represent the population  
134 (<http://www.raosoft.com/samplesize.html>). Out of 279 eligible participants, 171 participants with  
135 Bell's Palsy responded to the questionnaire accounting for a 61.2% response rate.

### 136 **Statistical Analysis**

137 The information and data from the study were entered into an electronic database (SPSS® for  
138 windows®V.20). The demographic data were analyzed through frequency distribution and the  
139 relation between various risk factors was analyzed by chi-square test, Fishers Exact test and  
140 Likelihood Ratio test. The total population of the Qurayyat region of Saudi Arabia in the year  
141 2020 was 180,430 (MOH). The incidence rate was calculated as number of new Bell's Palsy  
142 would appear annually for 100,000 people in a population. Incidence was calculated by the  
143 formula below.

144 *Incidence = Total number of cases identified (n=279) / Total population at Qurayyat region*  
145 *(n=180,430) \* 100,000 = 154.6 / 6 years (2015-2020) = 25.7 per 100,000 per year.*

### 146 **Results**

147 Among 171 Bell's palsy patients, the majority of participants were female (n = 147, 86%). Bell's  
148 Palsy was common among the 21-30-year age group (n=76,44.4%) and lowest among 1-10 years  
149 (n=11,6.4%). The highest number of participants reporting Bell's Palsy for the first time was  
150 (n=129, 75.45%) and recurrent Bell's Palsy reported was (n=18, 10.5%). There were n=21  
151 (12.3%) participants vaccinated before experiencing Bell's Palsy. (Table 1).

152 There was a significant number of participants (n=135,78.9%) exposed to cold air before  
153 experiencing Bell's Palsy. A Likelihood Ratio Test was performed to examine the relation  
154 between age groups and exposed to cold air before experiencing Bell's Palsy. The relationship  
155 between these variables was significant,  $\chi^2(5, N = 171) = 14.926, P = 0.011$ . The post hoc  
156 analysis with Bonferroni correction and adjusted P-value of 0.0072 to be significant at the  
157  $P < 0.05$  level, revealed 21-30 year age group was significantly affected. Sixty-five (38%)  
158 participants reported that their parents were cousins and n=20 (11.7%) reported having a  
159 familial-related genetic disorder. There was no significant relationship between the

160 consanguinity with gender, onset and reoccurrence of Bell's Palsy but consanguinity showed  
161 significant relationship with side affected and age group,  $\chi^2$  (2, N = 171) = 12.090, P = 0.002,  $\chi^2$   
162 (5, N = 171) = 13.025, P = 0.023 respectively,

163 The main therapeutic approach preferred was physiotherapy (n=149, 87.1 %), followed by  
164 corticosteroids and antiviral drugs (n=61, 35.7%), acupressure (n=35, 20.5%), traditional Saudi  
165 herb medicine (n=32, 18.7%), cauterization by hot iron rod (n=23, 13.5%), supplementary  
166 therapy (vitamins and neuro-vitality drugs (n=2, 1.2%), facial cosmetic surgery (n=1,0.6%) and  
167 no treatment (n=1,0.6%). The most preferred combination therapy was physiotherapy (87.6%)  
168 with corticosteroid and antiviral drugs (35.9%), and acupressure (17.6%) (Table 2)

169 There were relatively less number of participants suffering from ear infection (n=28, 16.4%),  
170 diabetes (n=23,13.5%), genetic disease (n=20, 11.7%), high blood pressure (n=18, 10.5%),  
171 neurological disorder (n=16, 9.4%), head injury (n=11, 6.4%), balance problem (n=10, 5.8%)  
172 stroke (n=3, 1.8%), and heart disease (n=3, 1.8%) (Figure 2).

## 173 Discussion

174 This study aimed to determine the incidence, risk factors and preferred treatment among  
175 participants with Bell's Palsy residing in the Qurayyat region of Saudi Arabia. According to this  
176 study, the females were predominantly affected and a significant number of participants opted  
177 for complementary and traditional therapy rather than research-recommended corticosteroid and  
178 antiviral drug therapy.

179 The average incidence of Bell's Palsy was found to be 25.7 cases per 100,000 per year in the  
180 Qurayyat region of Saudi Arabia. The most affected age group was 21-30 years with females  
181 6.12 times more affected than males. Physiotherapy and standard drug therapy (corticosteroid  
182 and antiviral drugs) are preferred over the other modes of treatment. A study conducted in the  
183 Arar region of Saudi Arabia found 26.3% of cases of Bell's Palsy with females (61%) more  
184 affected than males (Alanazi et al.). The authors also report that participants preferred  
185 physiotherapy treatment over drug therapy (Alanazi et al.).

186 Seventy-five percent of the participants with Bell's Palsy experienced sudden facial muscle  
187 paralysis. The majority of the participants experienced first-time facial paralysis with 10.5%  
188 reporting recurrent Bell's Palsy. Similarly, a study conducted in the Asir region of Saudi Arabia  
189 also found that the majority of participants reported sudden onset Bell's Palsy in winter. The  
190 author also reported 5.35 per 100,000 per year incidence of Bell's Palsy (Al Ghamdi). On the  
191 contrary, the incidence of Bell's Palsy in our study was approximately 25.7 per 100,000 per year.  
192 The incidence was calculated from the total population of the Qurayyat region, which was  
193 180,430 as per the 2020 population census of the Ministry of Health Saudi Arabia (Ministry of  
194 Health Saudi Arabia).

195 In our study, we found only 12.3% of participants reporting Bell's Palsy after the COVID-19  
196 vaccination. Similarly, a research study about the association of Bell's Palsy with COVID-19  
197 vaccination is scarce and few case reports have been presented but the incidence of Bell's Palsy  
198 after vaccination is low. Studies are reporting a significant association between vaccination and  
199 incidence of Bell's Palsy (Cirillo and Doan), however, the studies might have introduced

200 selection bias as selected age groups were vaccinated because the incidence of Bell's Palsy  
201 greatly varies with age (Li et al.). In our study, we found that 78.9% of participants reported  
202 Bell's Palsy after they were exposed to cold air. However, only 28.7% and 19.3% of participants  
203 reported catching a common cold and flu before suffering from Bell's Palsy. A study conducted  
204 among 1,181 active duty military service members in the USA reported 33% more incidence of  
205 Bell's Palsy in cold climate than in warm regions (Campbell and Brundage).  
206 Pre-existing conditions such as diabetes, middle ear infection, head injury, high blood pressure,  
207 head and neck surgery, stroke, genetic disease, neurological disorders, respiratory disease were  
208 reported by a small number of participants with Bell's Palsy. A case-control study conducted in  
209 Italy among 381 cases reported no significant difference due to the presence of hypertension or  
210 diabetes. However, the chances of Bell's Palsy increased linearly every year by 2% with age  
211 (Monini et al.).  
212 Research has reported that allopathic drug therapy to be recommended following Bell's Palsy (de  
213 Almeida et al.). The use of corticosteroids is recommended to avoid unsatisfactory patient  
214 outcomes and the addition of antiviral drugs therapy has additive benefits (De Almeida et al.).  
215 However, in our study, 64.3% of participants reported not taking recommended drugs. A review  
216 study by (Potterton) recommended using corticosteroids therapy within 72 hours of the onset of  
217 Bell's Palsy for a better outcome. Physiotherapy and allopathic drug therapy for 3-4 weeks  
218 following Bell's Palsy among participants were the favored treatment choice following Bell's  
219 Palsy. Complementary therapy such as acupuncture in the form of dry needling was reported by  
220 20.5% of participants. A study conducted among the general population (n=420) found only  
221 49.6 % favored steroid treatment while 54.7% favored traditional medicine (AlYahya et al.). A  
222 study conducted among dental students (n=654) reported only 39% of dental students favored  
223 corticosteroid therapy (Al Meslet et al.).  
224 Traditional Saudi medicine and cauterization (hot iron rod) were used by 18.7% and 13.5% of  
225 participants respectively. This traditional medicine is reported to cause severe burn injury and  
226 complicated wounds (Aboushanab and AlSanad).

### 227 **Limitations**

228 The study is a regional study and the number of participants was relatively small. The recall bias  
229 might have occurred because the study involved the participant's memory to remember the  
230 events from the past. The Qurayyat region of Saudi Arabia is relatively smaller than the other 13  
231 major provinces of Saudi Arabia. Therefore, the results cannot be generalized to the whole  
232 nation. The actual number of patients with Bell's Palsy in the Qurayyat region of Saudi Arabia  
233 could not be determined because some patients might not visit a hospital or choose traditional  
234 medicine. Such limitation was reduced in our study by regular public advertisement through  
235 pamphlets and announcements in public places.

### 236 **Clinical Implications**

237 The general public can be educated about the best treatment available for Bell's Palsy to avoid  
238 solely relying on traditional medicine. The Bell's Palsy is mostly occurring during winter season,

239 therefore hospitals and clinics must equip themselves with sufficient medications and medical  
240 doctors for better patient outcome.

## 241 **Conclusions**

242 The incidence of Bell's Palsy was approximately 25.7 per 100,000 per year in the Qurayyat  
243 region of Saudi Arabia. Exposure to cold air and influenza were significant risk factors  
244 associated with Bell's Palsy. Females were predominantly affected by Bell's Palsy in the  
245 Qurayyat region of Saudi Arabia. Bell's Palsy most commonly occurred in the age group 21-30  
246 years. The most favored treatment was physiotherapy following Bell's Palsy. The population in  
247 Qurayyat region of Saudi Arabia needs to be educated about the potential benefits of  
248 combination therapy for improved patient outcomes rather than relying upon complementary or  
249 traditional medicine alone.

## 250 **Acknowledgements**

251 Authors would like to thank all the patients with Bell's Palsy who participated in this study.
