**Objectives:** Complement activation is a critical feature in the development of systemic lupus erythematosus (SLE). Whether there are changes of complement components in the urine of SLE has not been reported. The aim of the study was to evaluate the complement-related proteins in the urine of SLE, verify differentially expressed proteins (DEPs) in the active phase of SLE, further explore their clinical application value. **Methods:** First, we used bioinformatics and functional enrichment to screen and identify the urine protein profile of SLE patients. Then, analyzed and verified the proteins related to the complement pathway by western-blot and Parallel Reaction Monitoring (PRM) technology. Further evaluated the relationship between urinary DEPs related to complement pathway and disease activity. **Results:** A total of 14 complement pathway-related proteins were screened for differences in expression between the active group and the stable group, eight of these DEPs were up-regulated and Six were down-regulated. These DEPs may play a key role in SLE disease activity. We used PRM technology to verify the eight up-regulated proteins, and found that four of these complement proteins, namely C9, C8A, C4B, and C8G, were significantly increased in active group. Furthermore, these four DEPs were highly correlated with disease activity. In the urine of SLE patients, AUCs of 0.750, 0.840, 0.757 and 0.736 were achieved with C9, C8A, C4B, and C8G, respectively. **Conclusions:** Complement-related DEPs in urine have a certain correlation with SLE disease activity. Urine C9, C8A, C4B and C8G present promising non-invasive biomarkers for monitoring lupus activity.

18 **Abstract**

19 **Objectives.** Complement activation is a critical feature in the development of systemic lupus  
20 erythematosus (SLE). Whether there are changes of complement components in the urine of SLE  
21 has not been reported. The aim of the study was to evaluate the complement-related proteins in  
22 the urine of SLE, verify differentially expressed proteins (DEPs) in the active phase of SLE,  
23 further explore their clinical application value.

24 **Methods.** First, we used bioinformatics and functional enrichment to screen and identify the  
25 urine protein profile of SLE patients. Then, analyzed and verified the proteins related to the  
26 complement pathway by western-blot and Parallel Reaction Monitoring (PRM) technology.  
27 Further evaluated the relationship between urinary DEPs related to complement pathway and  
28 disease activity.

29 **Results.** A total of 14 complement pathway-related proteins were screened for differences in  
30 expression between the active group and the stable group, eight of these DEPs were up-regulated  
31 and six were down-regulated. These DEPs may play a key role in SLE disease activity. We used  
32 PRM technology to verify the eight up-regulated proteins, and found that four of these  
33 complement proteins, namely C9, C8A, C4B, and C8G, were significantly increased in active  
34 group. Furthermore, these four DEPs were highly correlated with disease activity. In the urine of  
35 SLE patients, AUCs of 0.750, 0.840, 0.757 and 0.736 were achieved with C9, C8A, C4B, and  
36 C8G, respectively.

37 **Conclusions.** Complement-related DEPs in urine have a certain correlation with SLE disease  
38 activity. Urine C9, C8A, C4B and C8G present promising non-invasive biomarkers for

39 monitoring lupus activity.

40 **Keywords:** Urine; Complement; Differentially expressed proteins; Biomarker; Lupus.

## 41 **1 Introduction**

42 Systemic lupus erythematosus (SLE) is a global chronic autoimmune disease involving  
43 multiple organs. With the development of diagnosis and treatment technology, the survival rate  
44 of SLE has increased significantly, but it is still an irradicable disease[1]. SLE has the  
45 characteristics of repeated recurrence and remission. Relapsing is a common clinical feature, a  
46 sign of obvious disease activity, and the main cause of organ damage and poor prognosis[2].  
47 Autoantibodies, immune complexes and complement system in the immune system play an  
48 important role in the pathogenesis of SLE[3, 4]. Complement is an important effector system of  
49 the immune response. On the one hand, complement is the ultimate effector of tissue damage in  
50 autoimmune diseases; on the other hand, the lack of certain components of complement would  
51 lead to autoimmune diseases[5].

52 It has been found that many complement components were closely related to the occurrence  
53 and development of SLE. Serum low levels of complement C3, C4 and CH50 as indicators of  
54 lupus activity have been included in the Systemic Lupus Erythematosus Disease Activity Index  
55 2000(SLEDAI-2000) scoring system[6]. The relationship between serum C1q and the  
56 development of lupus is well known, it is typically involved in the clearance of apoptotic cells,  
57 and being a valuable biomarker of lupus activity[7, 8]. The genetic defects of complement C1,  
58 C2, or C4 are strongly associated with the development of SLE[7, 8]. Since most complement  
59 and activation products exist in plasma and are finally excreted in urine, these factors may be

60 used as non-invasive biomarkers for monitoring disease activity. In our early study, we used  
61 label-free technology to analyze the urine proteins between the active and stable group of SLE,  
62 and discovered many differentially expressed proteins (DEPs)[10].The changes of complement-  
63 related proteins in the active phase of SLE aroused our interest.

64 Therefore, in order to analyze the expression of complement-related proteins in the urine of  
65 SLE, we evaluated the urine protein expression profile during the active period of SLE.  
66 Subsequently, we verified the changes of these complement proteins in the urine of lupus by  
67 qualitative western-blot and quantitative proteomics technology, further explored the role of  
68 different complement components in lupus activity to provide a basis for discovering urinary  
69 biomarkers of lupus activity.

## 70 **2 Materials and methods**

### 71 **2.1 Patients and sample collection**

72 First of all, this study protocol was approved by the ethics committee of Beijing Shijitan  
73 Hospital, Capital Medical University (sjtkyll-lx-2021(55)) . The participants all gave written  
74 informed consent of each subject, which was in accordance with the provisions of the Helsinki  
75 Declaration. All subjects were adult females. Study participants included 24 patients with  
76 diagnosed systemic lupus erythematosus (SLE group) and 12 controls that did not have SLE (NC)  
77 with routine physical examination. Participants were recruited from Beijing Shijitan Hospital  
78 from September 2020 until September 2021. SLE patients were diagnosed through the use of  
79 1997 American College of Rheumatology classification criteria for systemic lupus erythematosus.  
80 According to the SLEDAI-2K scoring system, SLEDAI-2K $\geq$ 5 were classified as the active

81 group (SLE-A), and SLEDAI-2K<5 were classified as the stable group (SLE-S) . Exclusion  
82 criteria included acute or chronic infections, tumors and other autoimmune diseases, and any  
83 diagnoses of other severe liver and renal disease. The morning midstream urine samples were  
84 collected into sterile polypropylene tubes. Immediately after collection, urine samples were  
85 centrifuged at  $400\times g$  for 5 min to remove cell debris and casts and finally supernatants were  
86 divided in aliquots and frozen at  $-80^{\circ}\text{C}$ .

## 87 2.2 Proteomic analysis and bioinformatics analysis

88 Base on SDS Polyacrylamide Gel Electrophoresis(SDS-PAGE) combined with nano-  
89 upgraded reversed-phase liquid chromatography-tandem mass spectrometry (nanoRPLC-  
90 MS/MS)method, we detected and analyzed the urinary proteins of SLE patients and controls  
91 without SLE using Thermo Q-Exactive mass spectrometer. MaxQuant software was used to  
92 process the original mass spectrometry files, and the significant difference in protein  
93 quantification between SLE-A and SLE-S (Fold change=2.0,  $P<0.05$ ) was defined as  
94 differentially expressed proteins (DEPs). KEGG database and Metascape platform were used to  
95 analyze the function and pathway enrichment of DEPs to determine the important pathways and  
96 proteins related to SLE disease activity. Protein-protein interaction (PPI) network analysis is  
97 performed by using a search tool (STRING) database for searching interacting genes/proteins.

## 98 2.3 Qualitative identification by western blot.

99 To verify the previous screening results, we selected C9 and MASP2 with the most obvious  
100 differences for western blot analysis. The total protein was enriched by a 10kD ultrafiltration  
101 device (Millipore) and concentrated at 6000g for 15 minutes. The volume of the sample was

102 calculated according to the protein mass (7  $\mu\text{g}$ ). After SDS-PAGE gel electrophoresis, the protein  
103 was transferred to the PVDF membrane and sealed with skim milk powder for 2 hours. The  
104 PVDF membranes were incubated overnight at 1:1000 anti-C9 antibody and anti-MASP2  
105 antibody at 4°C. The 1×TBST buffer solution was used to rinse the membranes three times, each  
106 20 minutes. Then, 1:3000 second antibody was added and incubated at room temperature for 90  
107 minutes. Finally, the PVDF membrane was washed with 1×TBST buffer and detected by the  
108 enhanced chemiluminescence method.

#### 109 2.4 Quantitative identification by parallel reaction monitoring

110 The urinary samples were centrifuged at 2000g for 10min at 4°C, and urea particles were  
111 added to the supernatant with a urea concentration of 8M, shaken until the urea particles were  
112 fully dissolved. The volume of the samples were concentrated by ultrafiltration in a 10K  
113 ultrafiltration tubes. After protein quantification, 60 $\mu\text{g}$  proteins were taken and placed in a  
114 centrifuge tubes. 5 $\mu\text{l}$  of 1M DTT was added to the solution and mixed, and incubated at 37°C for  
115 1h; 20 $\mu\text{l}$  of 1M IAA solution was added, and after mixing, the reaction was performed for 1h at  
116 room temperature and avoided light. Trypsin was added to the ultrafiltration tube at 1:50  
117 enzyme-to-substrate ratio, and digested at 37°C for more than 12 hours. The mix-sample was  
118 fractionated in 100 $\mu\text{l}$  mobile phase A (100% ddH<sub>2</sub>O, 0.1% formic acid), centrifuged at 14000g  
119 for 20min, and the supernatant was taken for separation at a flow rate of 0.7ml/min. Finally, the  
120 eluates were monitored at UV 214 nm, collected for a tube per minute and merged into 3  
121 fractions, which are lyophilized and waiting for Q Exactive HF-X mass spectrometer testing.

122 The Q Exactive HF-X mass spectrometer was operated in the data-dependent acquisition

123 mode and there was a single full-scan mass spectrum in the Orbitrap (350-1500 m/z, 120,000  
124 resolution) followed by data dependent MS/MS scans in an Ion Routing Multipole at 27%  
125 normalized collision energy (HCD). The single-sample was reconstituted in 0.1% FA, and  
126 injected into the Q Exactive HF-X mass spectrometer (Thermo Fisher) operating in the Parallel  
127 reaction monitoring (PRM) mode. For PRM acquisition, primary mass spectrum (MS1)  
128 resolution was set to 120000, and secondary mass spectrum (MS2) resolution was set to 15000.  
129 The m/z range covered from 350 to 1500 m/z. The maximum capacity of C-trap was set to  $3 \times 10^6$ ,  
130 and the maximum injection was 80 ms. The dynamic exclusion range was set to 16 s and allow  
131 the mass spectrometer always operating in the parallel ion filling and detection mode. The raw  
132 data of mass spectrometry (MS) was generated and processed by Skyline software. The false  
133 discovery rate was set to 1% for proteins and peptides. The enzyme specificity was set to trypsin,  
134 and a maximum of three missed cleavages were allowed in the database search. Parameter  
135 settings for screening differential proteins: difference ratio  $>1.2$  or difference ratio  $<1/1.2$ ,  $P$   
136 value  $<0.05$ .

## 137 2.5 Statistical analysis

138 Statistical analysis was performed using SPSS 21.0 software and the visualization of the  
139 data carried out by using GraphPad Prism 9.0 software. The results of quantitative data were  
140 expressed as mean  $\pm$  standard deviation(SD) or median (interquartile range). The P-values were  
141 calculated by Student's t test and Mann-Whitney U test for two groups, or ANOVA (more than  
142 two groups). The correlation analysis was performed to examine the relationship between  
143 continuous variables by Spearman's correlation coefficient. Receiver operating characteristic

144 (ROC) curve analysis and area under the curve (AUC) calculations were used to analyze the  
145 diagnostic value of urine candidate DEPs in the disease activity of patients with SLE. In all cases  
146 two-tailed  $P < 0.05$  was accepted as statistically significant.

### 147 **3. Results**

148 **3.1 Comparison of complement-related proteins between active group (SLE-A)**  
149 **and stable group (SLE-S).**

150 Screening and identifying the urine protein profile of SLE patients demonstrated that  
151 complement-related proteins showed varying degrees of difference between the active group  
152 (SLE-A) and stable group (SLE-S). To classify the functional annotations of the identified  
153 proteins, pathway analysis was performed by Kyoto Encyclopedia of Genes and Genomes (KEGG)  
154 database. The most representative pathway was complement and coagulation pathways  
155 (map04610). Among the urine protein profile, there were 16 proteins involved in the  
156 complement pathway, 14 of these proteins were differentially expressed, 8 differentially  
157 expressed proteins (DEPs) were up-regulated, and 6 DEPs were down-regulated (Figure 1A).

158 These 14 DEPs played different roles in the complement pathway, 10 of these DEPs were  
159 key factors of the complement pathway. The expressions of Complement C5 (C5), Complement  
160 component C9 (C9), Complement C3 (C3), Complement component C7 (C7), Complement C4-  
161 B (C4B), Complement component C8 alpha chain (C8A) and Complement component C8  
162 gamma chain (C8G) were up-regulated between SLE-A and SLE-S, while the expressions of  
163 Mannan-binding lectin serine protease 2 (MASP2), Complement component C6 (C6) and  
164 Complement factor D (CFD) are down-regulated. The other 4 DEPs were the inhibitory

165 molecules of complement pathway, namely Vitronectin (VTN) whose expression was up-  
166 regulated and Complement receptor type 1(CR1), Plasma protease C1 inhibitor (SERPING1) and  
167 V-set and immunoglobulin domain-containing protein 4(VSIG4) whose expression were down-  
168 regulated (Figure 1B). The relative abundance of these DEPs among SLE-A, SLE-S and controls  
169 that did not have SLE (NC) were shown in Figure 1C, and detailed information were shown in  
170 Table 1. These DEPs may play key roles in disease activity.

### 171 3.2 Bioinformatics analysis of complement-related proteins

172 In order to predict the interactions of complement-related proteins, protein–protein  
173 interaction (PPI) network was conducted by STRING database. The PPI network involved in the  
174 complement pathway were tight and these proteins had strong interactions(Figure 2A). Based on  
175 the Metascape platform, the functional analysis of these proteins revealed that the main  
176 enrichment pathways involved in complement and coagulation cascades, complement cascade,  
177 complement activation, regulation of complement cascade and other pathways. These findings  
178 suggested that these proteins play important roles in the activation and regulation of the  
179 complement pathway (Figure 2B).

### 180 3.3 Preliminary verification of urine C9 and MASP2 among SLE-A, SLE-S and 181 controls group (NC)

182 To verify the screening results, we selected the two most different proteins from the DEPs,  
183 namely C9 and MASP2, performing western blot analysis. The results showed that the  
184 expression of C9 in the urine was significantly increased in most patients with SLE-A compared  
185 with SLE-S and NC. But the changes of MASP2 in the three groups were not obvious, and even

186 the detection rate of MASP2 in the urine of individual SLE patients and control groups was low  
187 (Supplementary Figure 1). It may be due to the limitations of the western blot method in the  
188 detection of urine proteins, and the sensitivity is not enough. Therefore, we focused on the up-  
189 regulated proteins for further verification.

### 190 3.4 Quantitative verification of up-regulated complement proteins in urine

191 Parallel reaction monitoring (PRM) technology was used to identified 8 up-regulated  
192 proteins related to the complement pathway. The results revealed that the expression of 4  
193 proteins were consistent with the previous mass spectrometry screening results. The detailed  
194 information of the four proteins were shown in Table 2. Compared with the SLE-S and NC, the  
195 expression levels of C9, C8A, C4B, and C8G exhibited a significant increase in urine of SLE-A.  
196 The levels of these four proteins among the three groups are shown in Figure 3A.

### 197 3.5 Differentially expressed proteins (DEPs) were closely associated with lupus 198 activity

199 Spearman correlation analysis was used to analyze the correlation between four DEPs and  
200 disease activity. The results shown that the levels of urine C9 ( $r=0.599$ ,  $P=0.002$ ), C8A ( $r=0.669$ ,  
201  $P<0.001$ ), C4B ( $r=0.588$ ,  $P=0.003$ ), and C8G ( $r=0.597$ ,  $P=0.002$ ) were significantly positively  
202 correlated with SLEDAI-2K. The higher the score of SLEDAI-2K, the greater the concentration  
203 of these four proteins (Figure 3B).

204 ROC curve analysis was performed to determine the cutoff value of the four DEPs for  
205 distinguishing SLE-A from SLE-B. The areas under the curves(AUCs) of urine C9, C8A, C4B  
206 and C8G were 0.750 (95% CI: 0.554-0.947), 0.840 (95% CI: 0.674-1.00), 0.757(95% CI: 0.556-

207 0.958) and 0.736 (95% CI: 0.526-0.946), respectively(Figure 3C). These four proteins all have  
208 high discriminatory capacity for disease activity. Among the four urinary proteins, C8A had the  
209 highest judgment value for lupus activity, with an AUCs of 0.840. When the cutoff level was  
210 0.640 ng/ml, the sensitivity and specificity were 91.67% and 75%, respectively.

#### 211 **4. Discussion**

212 Although the pathogenesis of SLE is not fully understood, it is widely accepted that the  
213 complement system in the blood is involved in the pathogenesis of SLE and has important roles  
214 in the pathophysiology of SLE, including promotion of inflammatory processes, clearance of  
215 immune complexes, cellular and apoptotic debris[11-13].The complement system is composed of  
216 more than 30 plasma proteins and cell surface receptors. There are three pathways of  
217 complement activation: classical pathway, alternative pathway and mannose-binding lectin  
218 pathways, which may be related to inflammation and tissue damage in SLE[14-16].Therefore,  
219 activating components or products of complement in SLE patients may serve as biomarkers for  
220 diagnosis or monitoring disease activity of SLE.

221 In the past few decades, most studies have focused on the detection of complement proteins  
222 (C3, C4) and hemolytic activity. Although known as markers of disease activity, the limitations  
223 of these indicators have also caused some controversy[17-19].In recent years, some studies have  
224 found that detection of complement split products more accurately reflected complement  
225 activation, such as C3a, C4a, C5a, C3d, C4d, Ba, Bb and soluble C5b-9 complexes[20-  
226 22].However, these split products have a short half-life in plasma and are easily activated in vitro,  
227 so there are many challenges in detection technology[23].The content of proteins in urine is

228 relatively stable, and urine is easy to collect and available in large quantities[24].Therefore, the  
229 detection of complement components and split products in urine is a convenient and good choice.

230 Several investigators reported that the complement split products like C3 fragment, C4d,  
231 C5a and C5b-9 could be detected in the urine of lupus nephritis (LN) patients, and found that the  
232 levels of C3d in urine was closely related to LN disease activity[25, 26]. Whereas, the changes of  
233 other complement pathway-related proteins and fragments in the urine of SLE patients are  
234 unknown. Therefore, in order to explore the changes of complement components in the urine of  
235 SLE patients and the relationship with SLE disease activity, and search the potential urine  
236 markers of monitoring SLE activity, we analyzed the urine protein profiles of patients with  
237 active lupus and stable lupus, and screened out the urinary proteins involved in the complement  
238 pathway, based on label-free mass spectrometry technology. Subsequently, we further  
239 investigated the expression levels and functions of the complement related DEPs between the  
240 active group (SLE-A) and stable group (SLE-S). Then, the up-regulated DEPs were selected for  
241 quantitative verification using targeted proteomics technology to explore the clinical application  
242 value of these urinary proteins as biomarkers of disease activity.

243 In this study, a total of 16 complement pathway-related proteins were identified by  
244 analyzing the urine protein profiles of SLE, 14 of these proteins were abnormally expressed in  
245 the active and stable SLE groups. Through functional analysis, we found that these differential  
246 proteins have different roles in the complement pathway, mainly involved in complement  
247 activation and the regulation of complement activation pathway, and these DEPs may as crucial  
248 markers for SLE disease activity. To verify the expression of these DEPs in the urine of SLE

249 patients, we focused on the verification of 7 up-regulated proteins relating to complement  
250 activation pathway (C5, C9, C8A, C3, C7, C4B and C8G). Our results showed that the  
251 expression of urinary C9, C8A, C4B and C8G in SLE patients was consistent with previous mass  
252 spectrometry data.

253 C9, C8 (C8A, C8G) are both the final components of the complement system, major  
254 components of the membrane attack complex (MAC), which served as part of innate and  
255 adaptive immune responses[27]. C8 contains three polypeptides, ( $\alpha$ ,  $\beta$ , and  $\gamma$ ), consisting of  
256 disulfide-linked heterodimers ( $\alpha$ - $\gamma$ ) and non-covalently bound  $\beta$  chains[28]. C9 binds C8 in the  
257 C5b-8 complex and forms the MAC that causes cellular and organ damage, therefore, the  
258 complement system is involved in the occurrence and development of various diseases[29].  
259 Recent evidence reported that the decrease of eGFR in patients with diabetic nephropathy was  
260 significantly associated with the excretion of the urinary membrane attack complex[30]. Our  
261 results revealed that urinary complement C9, C8A and C8G were significantly increased during  
262 active SLE, and correlated well with SLEDAI-2K, suggesting complement activation and the  
263 formation of membrane attack complexes during SLE disease activity.

264 C4 is a non-enzymatic component of C3 and C5 convertases and is necessary for  
265 complement activation[31]. After complement was activated through the classical or lectin-  
266 activated pathway, C4 was activated and hydrolyzed to generate C4B. C4B was an opsonin that  
267 covalently binds complement-activating targets[32]. Recent studies have reported that diversities  
268 of C4A and C4B proteins and their gene copy number variations (CNVs) in healthy subjects and  
269 patients with autoimmune diseases[33]. Our results demonstrated that the expression of C4B was

270 also significantly elevated in the urine of active SLE, and was positively correlated with disease  
271 activity.

272 Furthermore, in the ROC curve analysis of urine C9, C8A, C8G and C4B on SLE disease  
273 activity, we found that these four proteins all have good ability to judge SLE activity. Among  
274 these proteins, urine C8A had the best judgment ability, with an AUC of 0.840. When the cut-off  
275 value was 0.640 ng/ml, the sensitivity and specificity for judging disease activity were 91.67%  
276 and was 75%, respectively. These four complement related DEPs undertook critical roles and  
277 performed different functions in the complement cascade (Figure 4). As the important  
278 component of C3 convertase and C5 convertase, C4b played a very important role in the entire  
279 complement cascade. While C9, C8A, and C8G were mainly involved in the last step of the  
280 complement cascade, which participated in the formation of membrane attack complexes,  
281 resulting in cell lysis and tissue damage. According to our results, urine C9, C8A, C8G, and C4B  
282 were significantly increased during active SLE, the four complement-related proteins may be  
283 potential urinary biomarkers of SLE disease activity.

## 284 **5. Conclusions**

285 In conclusion, we analyzed and verified the expression of complement pathway-related  
286 proteins in the urine of SLE patients with different activity states by using proteomic technology.  
287 Then, we further explored the association between these complement-related proteins and  
288 disease activity. Higher abundance of urinary C9, C8A, C8G, and C4B were strongly associated  
289 with higher scores of SLEDAI-2K. These findings suggested that activation of distinct  
290 components of the complement pathway may be associated with disease activity. Consequently,

291 therapeutically targeting the complement pathway may improve progression of SLE and these  
292 four urinary proteins may be potential biomarkers to assist in monitoring lupus activity.

### 293 **Statement of Ethics**

294 This study was approved by the ethics committee of Beijing Shijitan Hospital, , Capital  
295 Medical University. The participants all gave written informed consent of each subject, which  
296 was in accordance with the provisions of the Helsinki Declaration.

### 297 **Conflicts of Interest**

298 Upon manuscript submission, all authors completed the author disclosure form. The authors  
299 declare no competing interests.

### 300 **Acknowledgments**

301 The authors would like to thank: Beijing Health Commission for the Grant financial support  
302 (Grant Number 2020ZDZK2, Grant name: Beijing Key Clinical Specialty Project).

303

## 371 **Figures and Legends**

372

373 **Figure 1. Comparison of urine proteins related to complement pathway.** (A) Heatmap of  
374 candidate urine proteins among active group (SLE-A), stable group (SLE-S) and controls  
375 without SLE (NC). (B) Different roles of differential proteins in the complement pathway  
376 between SLE-A and SLE-S. (C) The abundance of these complement related proteins in arbitrary  
377 units among three groups.

378

379 **Figure 2. Functional analysis of complement-related proteins.** (A) Protein–protein  
380 interaction(PPI) network of complement-related proteins. The confidence level was set to  
381 medium of 0.4. (B) Pathway analysis of complement-related proteins performing by Metascape  
382 platform.

383

384 **Figure 3. The comparison of selected protein expression by PRM.** (A) The expression levels  
385 of C9, C8A, C4B and C8G among active group (SLE-A), stable group (SLE-S) and controls  
386 without SLE (NC). An asterisk (\*) indicated a significant change in protein abundance between  
387 the two groups ( $P<0.05$ ) and two asterisk (\*) meant  $P<0.01$ . (B) The correlation between DEPs  
388 and SLEDAI-2K, including C9, C8A, C4B and C8G, was determined by Spearman correlation  
389 analysis in SLE patients. (C) Receiver operating characteristic (ROC) curve analysis of the four  
390 DEPs to distinguish SLE disease activity from SLE stable. PRM: Parallel reaction monitoring;  
391 DEPs: differentially expressed proteins; SLEDAI-2K: Systemic Lupus Erythematosus Disease  
392 Activity Index 2000; AUC: area under the curve.

393

394 **Figure 4. Simplified complement cascade featuring complement-related proteins.** C9, C8A,  
395 C4B and C8G play different roles in the complement pathway. Red indicating the four  
396 significantly up-regulated proteins or protein complex.

397

398 **Supplementary Figure 1. The expression of urine C9 and MASP2 determined by western**  
399 **blotting among active group (SLE-A), stable group (SLE-S) and controls without SLE (NC).**  
400 The total protein were enriched from the urine of each subject. A1-A12: Western blot bands in  
401 the urine from 12 SLE-A patients. S1-S12: Western blot bands in the urine from 12 SLE-S  
402 patients. N1-N12: Western blot bands in the urine from 12 controls without SLE.
