Background: The Mini Nutrition Assessment (MNA) is a widely used and valid tool for screening and assessment of malnutrition among the elderly population worldwide. However, MNA has not been validated among the Ethiopian elderly population and this study assessed the validity of the tool for the target population. **Methods**: Cross-sectional validation study design employed to validate MNA in Meki town, East Ethiopia. This study included 176 randomly selected elders living in the community, whereas amputated, bedridden, visible deformity, known liver and/or renal disorders were excluded. Original MNA questionnaires were translated to local language and administered to each participant after doing the pretest. The anthropometric, self-perception of nutritional status and serum albumin concentrations were measured. Reliability, validity, sensitivity, specificity, Positive Predictive Value (PPV), and Negative Predictive Value (NPV) were calculated. Receiver-operating characteristic (ROC) curve analysis was plotted to identify the Area Under the Curve (AUC) and optimal cut-off value for the prediction of malnutrition. **Result:** A total of one hundred and seventy-six elders participated in this study. Of the total participants, 78(44.3%) were males. The mean (SD) age of the participants was 67.6 (±5.8) years and ranged from 60 to 84 years. The prevalence of malnutrition based on the MNA criteria (MNA<17 points) was 18.2%, and 13.1% based on serum albumin concentration (<3 g/dl).The MNA had an overall Internal consistency of Cronbach's alpha 0.61. The tool also demonstrated significant criterion-related validity (0.75, p<0.001) and concurrent validity (0.51, p<0.001) with serum albumin concentration and self-perception of nutritional status respectively. Using the original cut-off point; the sensitivity, specificity, PPV and NPV of the tool were93.5%, 44.6%, 65.4% and 86.0% respectively. By modifying, the cut-off point to a value of < 20.5, the sensitivity and specificity of the tool increases to 97.6% and 82.8% respectively. The AUC (*95%CI)* showed an overall accuracy of 92.7% (88.5, 96.9). **Conclusion:** The MNA tool can be used as a valid malnutrition screening tool for the Ethiopian elderly population by modifying the original cut-off point.

7 **Abstract**

8 **Background**: The Mini Nutrition Assessment (MNA) is a widely used and valid tool for screening

9 and assessment of malnutrition among the elderly population worldwide. However, MNA has not

10 been validated among the Ethiopian elderly population and this study assessed the validity of the

11 tool for the target population.

12 **Methods**: Cross-sectional validation study design employed to validate MNA in Meki town, East

13 Ethiopia. We included 176 randomly selected elders living in the community, whereas amputated,

14 bedridden, visible deformity, known liver and/or renal disorders were excluded. Original MNA

15 questionnaires were administered to each participant after doing the pretest. The anthropometric

16 and serum albumin concentrations were measured. Reliability, validity, sensitivity, specificity,

17 Positive Predictive Value (PPV), and Negative Predictive Value (NPV) were calculated. Receiver-

18 operating characteristic (ROC) curve analysis was plotted to identify the Area Under the Curve

19 (AUC) and optimal cut-off value for the prediction of malnutrition.

20 **Result:** A total of one hundred and seventy-six elders participated in this study. Of the total

21 participants, 78 (44.3%) were males. The mean (SD) age of the participants was 67.6 (±5.8) years

22 and ranged from 60 to 84 years. The prevalence of malnutrition based on the MNA criteria

23 (MNA<17 points) was 18.2%, and 13.1% based on serum albumin concentration (<3 g/dl). The

24   MNA had an overall Internal consistency of Cronbach's alpha 0.61. The tool also demonstrated

25   significant criterion-related validity (0.75, p<0.001) and concurrent validity (0.51, p<0.001) with

26   serum albumin concentration and self-perception of nutritional status respectively. Using the

27   original cut-off point; the sensitivity, specificity, PPV and NPV of the tool were 93.5%, 44.6%,

28   65.4% and 86.0% respectively. By modifying, the cut-off point to a value of < 20.5, the sensitivity

29   and specificity of the tool increases to 97.6% and 82.8% respectively. The AUC (*95% CI)* showed

30   an overall accuracy of 92.7% (88.5, 96.9).

31   **Conclusion:** The MNA tool can be used as a valid malnutrition screening tool for the Ethiopian

32   elderly population by modifying the original cut-off point.

45

46

Background

48 Elderly people refer to those who are 60 years and above [1, 2], and currently, it is increasing at a

49 faster rate. Every second two persons celebrate their 60th birthday globally. By 2050 the elderly

50 population is expected to double in the world [3]. In Europe alone, the elderly population will

51 constitute about thirty-four percent of the entire population by 2050 [4]. Even, in developing

52 countries like Ethiopia elderly populations are rising, and they represent about 3.3% (3.3 million)

53 of the 110 million population, with 4.42% of the total population living in the Urban area [1]. In

54 addition, the country's life expectancy has increased to 67.8 years [5, 6]. Obviously, with aging

55 the elderly population's risk of developing communicable and non-communicable diseases

56 increases [7]. Hence, maintenance of optimum nutrient consumption in these age groups is of

57 paramount importance to prevent diseases [8]. Especially in this century, elderlies are prone to

58 the dual burden of malnutrition; under- nutrition or over-nutrition [9], and chronic non-

59 communicable diseases [10-12].

60

61 Protein-energy malnutrition, a condition resulting from inadequate consumption of nutrients [13],

62 is a specific concern in the elderly population because it is associated with increased morbidity

63 and mortality [14]. The magnitude of malnutrition varies from setting to setting. In developed

64 countries prevalence of malnutrition is reported to be 15%, among community members, 23 - 62%

65 in hospital settings, and more than 80% in intensive care units [15]. In developing countries like

66 South Africa, for instance, the prevalence of malnutrition is reported to be 50% in hospital settings

67 [16]. The figure is more or less similar in Chile, where the prevalence is 58% among the hospital

68 population [17].

69

70   In Africa, among community populations, the prevalence is reported to be 26.5% in Egypt [18],

71   and 28.3% in Ethiopia [19]. Given the elderly population's increasing population size and risk of

72   malnutrition; it is crucial to devise methods of early detection. For effective screening and

73   detection of malnutrition, a valid and reliable malnutrition screening tool is necessary [20]. This

74   further assists those elders who need intervention [21]. Malnutrition screening tools are mostly

75   easy to administer and contain structured questionnaires that include questions related to the

76   difficulty of chewing, appetite loss, or functional limitations. The tools also enable documentation

77   of indicators of malnutrition, like involuntary weight losses [22]. However, the validity of these

78   tools is very crucial to carry out the screening process so that one can measure what it is intended

79   to measure as far as malnutrition is concerned [14, 23].

80

81   There are different valid screening tools used to screen malnutrition among geriatrics, and the Mini

82   nutrition assessment (MNA) is the most widely used [24]. This tool was developed in the early

83   1990s and published in 1994 [25]. It is a short and simple tool that takes 10-15 minutes to complete

84   [26]. It has 18-items with four categories (anthropometric assessment, dietary assessment, global

85   assessment, and subjective assessment). All the eighteen items attribute to a score with a maximum

86   of 30-points. Based on the final score it categorizes the population into three groups: malnutrition

87   if the score is < 17 points, at risk of malnutrition, for scores between 17-23.5 points, and well-

88   nourished, if the score is between 24 and 30 points, inclusive [27].

89   It is the only nutritional screening and assessment tool that incorporates functionality, mobility,

90   and depression [28, 29]. Moreover, it is reliable, inexpensive, does not require laboratory

91   investigation, and is used in all settings [25, 30]. It is also able to detect risks of malnutrition before

92   the severe change in individuals' weight or serum albumin occurs [30]. It also correlates with serum

93   albumin concentration [31]. Reports also indicated that it predicts mortality and length of stay in

94   hospital [32]. There are hundreds of proteins circulating in plasma and serum albumin is one. To

95   measure this one needs a serum fluid that remains after plasma has clotted, fibrinogen, and most

96   of the clotting factors removed [33, 34]. The normal range of protein is 6.5-8.5 g/dl[35, 36] and

97   out of this albumin accounts large proportion (50-60%), with a normal value ranging from 3.5-5

98   g/dl[35, 36]. It has a half-life of 20 up to 22 days. Whereas its precursor pre albumin (transthyretin)

99   has only 2 to 4 days [37]. A systematic review of literature conducted by Zhang and colleagues in

100   2017, recommended the use of albumins and other biomarkers including pre- albumin,

101   hemoglobin, total cholesterol and total protein for the elderly's nutritional assessment, regardless

102   of body's inflammation status [38]. The pre-albumin (transthyretin), retinol-binding protein and

103   transferring are markers of short-term nutritional status[39]. Serum albumin is also used as a

104   predictor of morbidity and mortality in elderly people[40]. Based on serum level of albumin

105   nutritional status of elderly population can be categorized as malnutrition if < 3.0 g/dl, at risk if 3

106   to 3.5 g/dl, and well-nourished if > 3.5 to 5 g/dl[41, 42].

107

108   Even though MNA is validated and used in a different country, it is not readily applicable to other

109   countries. In part this is due to varying characteristics of the population's anthropometric

110   measurement and nutritional characteristics; from one setting to the other. For instance, MNA was

111   not applicable in the Chilean population [17]. The original cut-off value was also not reliable for

112   Irian elders [43], and Japan's population as well [44]. In Ethiopia, MNA has not been tested on

113   the elderly population and there is a gap of established cut-off points, to screen and assess

114   malnutrition. Therefore, this study attempted to validate MNA using serum albumin concentration

115   as a golden standard in the Ethiopian geriatric population.

116

Methods

117

Participants

118

119   The study was conducted in Meki town, Eastern part of Ethiopia from March to April 2020.

120   Initially, we conducted a house-to-house survey to estimate the total number of elderly people

121   (aged 60 and above) living in the setting. Each were given a unique identifier to help us develop a

122   sampling frame. At this stage, we have also secured contact information to make data collection

123   smooth. Following this, we calculated the sample size needed using BUNDER'S FORMULA

124   [45], and our calculation yielded 176 study participants. Recruitment was then followed afterward

125   using a computer-generated simple random sampling technique. Using the unique identifier and

126   the contact information we have secured at the earlier stage, from our sampling frame we have

127   approached those elders otherwise healthy, do not have any signs of deformity, amputation, not

128   incapacitated, do not have known liver and kidney disorders. We have then presented detailed

129   information about the nature of the study, and after consent was provided, detailed data were

130   obtained from the individual.

Nutritional assessment

131

132   A human blood sample (4 mL) was collected in the morning before 9:30 am, after a full overnight

133   fast, using a cupper-and zinc-free syringe. Serum albumin concentration was measured by

134   automated Bromocresol green method using BCG reagent and its standard manufactured by

135   Jourilabs [46]. All samples were handled according to WHO guidelines on standard operating

136   procedures for clinical chemistry [36], and reagent with its standard manufacturer order[46]. It

137   classifies as malnutrition if score is < 3.0 gram/deciliter (g/dl), at risk of malnutrition if score is 3

138   to 3.5 g/dl, and well-nourished for score between 3.5 to 5 g/dl [31, 41, 42].

139

140   Pre-tested Original MNA questionnaires [see Additional file 1] were administered to all

141   participants. The MNA® was used in accordance with Nestlé's terms and conditions [27].

142   All participants' weight, height, Mid-upper arm circumference (MUAC), and calf-

143   circumference (CC) were measured twice, and the average record was used for this study.

144   Height was measured using a stadiometer (Seca 213, Germany), participant bare feet, with

145   their buttock, heels, and occiput touching the board. Participants' height was recorded to the

146   nearest 0.1centimeters (cm). Weight was recorded to the nearest 0.1 kilograms (kg); using

147   calibrated digital scales placed on a hard flat surface with subjects in light clothes and bare

148   feet. The weighing scale was checked after each measurement with a 2kg standard weight.

149   MUAC was recorded to the nearest 0.1cm and was measured at the mid-point, between the

150   tip of the Acromion and Olecranon process on the back of the upper arm while the subject's

151   forearm held a freely horizontal position. CC was measured at the widest circumference

152   between ankle and knee and was recorded to the nearest 0.1 cm, using a flexible tape in a

153   sitting position, with a leg 90-degree (90°) at the knee. Body mass index (BMI) was

154   computed as body weight in kilograms divided by the squares of height in meters. All data

155   were collected by trained Nurses and laboratory professionals.

156   **Data processing and analysis**

157   The data were first entered into Epidata version 3.1, then exported to and analyzed by the IBM

158   Corp. Released 2017. IBM SPSS Statistics for Windows, Version 25.0 Armonk, NY: IBM Corp.

159   Variables of interest were described using means, standard deviations (SD), frequencies, and

160   percentage (%). A P-value < 0.05 was used to define statistical significance. To assess the

161   reliability of the MNA instrument in the population, the overall internal consistency was evaluated

162   by Cronbach's alpha. Usually, an alpha value of ≥ 80 is considered good, however, a value of 0.70-

163   80 and 0.60 - 0.70 is adequate and acceptable respectively [47]. Also, Spearman's rank correlation

164   coefficient for all the 18-items was calculated as well.

165

166   To calculate the criterion-related validity of the tool by comparing it with the gold standard[48],

167   we have assessed the correlation (Spearman's rho) coefficient between MNA and serum albumin

168   concentration. A value of 0.90 - 1.00 is considered very high and ≤ 0.50 low, whereas, values of

169   0.50-0.70 and 0.70- 0.90 are considered moderate and high respectively [49]. Concurrent validity

170   [48], was assessed again using Spearman's rank coefficient between MNA items and participants'

171   self-perception of nutritional status. In addition, we assess Concurrent validity using the

172   correlation between MNA and BMI classification of nutritional status.

173

174   Agreement between the two methods the MNA tool and serum albumin concentration was assessed

175   by calculating a weighted kappa coefficient. A kappa value of 0.80 -1.0 is considered perfect

176   agreement[50]. The sensitivity, specificity, positive predictive value (PPV), and negative

177   predictive value (NPV) were calculated using serum albumin concentration as a golden standard.

178

179   The markers of malnutrition considered for the analysis are if the MNA score is < 24 points or

180   serum albumin concentration is < 3.5g/dl. A receiver operating characteristic curve (ROC) was

181   plotted using serum concentration < 3.5 g/dl as a marker of malnutrition. The area under the ROC

182   curve (AUC) was evaluated to determine the overall accuracy of the MNA tool and usually, a

183   value ≥ 0.9 is considered excellent [51]. The optimal cutoff value was calculated using Youden's

184   J index (sensitivity + specificity -1) [52].

185   **Ethical Review and Participants consent**

186

187   This study was conducted according to the guidelines laid down in the World Medical

188   Association (WMA) Declaration of Helsinki and all procedures involving research study

189   participants were reviewed and approved by Jimma University, Institute of Health, Ethical review

190   committee (ERC) with ref no IRB 0063/2020. Written informed consent was obtained from all

191   participants.

208 **Results**

209 A total of 176 elders participated in the study, and the response rate was 100%. The mean (SD)

210 age of the participants was 67.86 (±5.8) years and 98 (55.7%) were females. Overall, mean (SD)

211 of the total MNA score was 20.7(3.5), and the mean (SD) of the serum albumin concentration was

212 3.7 (0.60) (Table 1).

213 Table 1: Characteristics of study participants elderly people aged 60 and above years in the

214 community, Meki town, East Ethiopia, 2020.

223

224

225

226

227

228

229   The internal consistency of the MNA tool was adequate (Cronbach α = 0.61). Homogeneity

230   between the eighteen MNA items was adequate with Cronbach's Alpha of 0.61. Cronbach's alpha

231   if an item deleted ranged from 0.526 to 0.633. The Scale's Cronbach's alpha would be 0.633 if the

232   acute stress item were removed from the scale (Table 2). But, in this study, no item was removed

233   and we used Cronbach α = 0.61 throughout the analysis. In addition, MNA's total score

234   significantly correlates with all its items (r_s > 0.242, P < 0.05).

235   Table 2:Cronbach's alpha for the MNA tool applied in the elderly population aged 60 and above

236   years in the community, Meki town, East Ethiopia, 2020.

237

238

239   Criterion-related validity of the MNA tool was tested by correlating it with the serum albumin

240   concentration, and the result was statistically significant (r_s = 0.746, P < 0.05). Similarly, the

241   concurrent validity of the tool was calculated by correlating the total scores of the item with the

242   BMI classification of nutritional status and the result was again significant (r_s= 0.392, P < 0.05).

243   Similarly, the MNA tool and self-perceived nutritional status correlated significantly (r_s = 0.514,

244   P < 0.05) (Table 3). According to the original cut-off point, MNA had a sensitivity of 93.5 %,

245   specificity of 44.6% PPV 65.4%, and NPV 86% of MNA with a total diagnostic accuracy of 70.5%

246   (Table 3).

247   Table 3: Measure of correlation, agreement, and diagnostic test between MNA and serum albumin

248   of participant elderly aged 60 and above years in the community, Ethiopia, 2020.

249

250

251

252

Figure 1:The ROC curves of one hundred and seventy-six samples for the MNA tool as compared to serum albumin concentration of participant elderly people aged 60 and above years in the community, Meki town, East Ethiopia, 2020.

256

The area under ROC curves using the serum albumin concentration level as golden standard area

showed the highest values of 0.927 (Figure 1). The AUC (95% CI) value indicates that MNA had

excellent diagnostic accuracy to diagnose malnutrition with an overall accuracy of 92.7 % (88.5,

96.9). In addition, Maximum Youden's J index calculated using the ROC curve was 0.804. At

this Youden's index value, the newly developed optimal cut-off value for the MNA tool was 20.5

to detect the markers of malnutrition (i.e. merged at risk of malnutrition and malnutrition). Based

on this cut-off value, the MNA total score of < 20.5 points, as markers of malnutrition, the

sensitivity increased to 97.6%, and specificity increased to 82.8%.

265

267

Discussion

269 The MNA long-form had adequate predictive ability of markers of malnutrition as compared to

270 serum albumin concentration level, among the elderly community population. It showed high

271 sensitivity and specificity, with a somewhat modified optimal cut-off value. Using the original cut-

272 off value, its sensitivity, diagnostic accuracy and overall diagnostic accuracy were 93.5%, 70.45%,

273 and 92.7% respectively. Our data also suggests that the MNA long-form is valid, with a cut-off

274 value of 20.5, using serum albumin concentration (<3.5g/dl) as a golden standard. This optimal

275 cut-off value had a sensitivity of 97.6% and a specificity of 82.8%. Moreover, the MNA long-form

276 had a strong agreement with serum albumin concentration, for identifying elderly individuals with

277 malnutrition or those at risk of malnutrition (weighted kappa= 0.556 (0.470, 0.642). The

278 prevalence of malnutrition using serum albumin concentration was found to be 13.1%. Compared

279 to the gold standard, the MNA long-form overestimates malnutrition by 5.1 %.

280 We evaluated the reliability and validity of the MNA tool among the elderly population of Ethiopia

281 living in Meki town. Similar to other reports, we have found that the tool is easy to administer and

282 use [25-27, 30, 53]. Our results indicated that the MNA tool had acceptable overall internal

283 consistency with a Cronbach's alpha score of 0.605. Hence, it seems reasonable to assume that the

284 MNA tool is reliable, measures what it intends to measure, and the scale is consistent and

285 homogeneous, at least in our sample.

286

287 To demonstrate the validity of the MNA tool, it is common practice in the field to calculate the

288 correlation of the MNA tool with serum albumin concentration. In this regard, a strong significant

289 positive correlation was detected (r_s=0.746), contributing to the tools' criterion-related validity.

290   Similarly, the tool demonstrated statistically significant concurrent validity with BMI nutritional

291   status classification and self-perceived nutritional status. Furthermore, the MNA tool had a

292   moderate agreement with serum albumin concentration level with a weighted kappa value of 0.556.

293   All these results indicate the appropriateness of the tool for the population under study.

294

295   Employing originally established cut-off value, the MNA had 93.5%, 44.6% and 65.4%

296   Sensitivity, specificity and PPV respectively. The tool also demonstrated an excellent overall

297   diagnostic accuracy with a value of 92.7%. These results are comparable with other findings

298   conducted elsewhere. Even though studies from settings like Turkey reported that the MNA tool

299   had a sensitivity of 92% [54], others have reported somewhat lower values; like Spain, 85.1 %

300   [55], Iran 82 % [43], Brazil 89% [56], Japan 81% [44] , and Nepal 86% [57]. If, however, we used

301   the value reported by the MNA tool developers, the results in this study are relatively low. The

302   originally reported values for sensitivity and specificity are 96% and 98% respectively.

303

304   This is not surprising as such variations in sensitivity and specificity could arise from the nature

305   of the study population, sampling technique and golden standard used to validate the MNA tool.

306   Hence, this study supports the use of MNA as a reliable and valid tool for screening malnutrition

307   among the elderly population living in the Ethiopian community. However, according to the newly

308   developed best-fit cut-off value for the MNA tool (score of < 20.5), the sensitivity increased to

309   97.6% and specificity increased to 82.8%. This new optimal cut-off value, however, decreased

310   the diagnostic accuracy to 80.4%. Therefore, all in all, with the updated cut-off value, the

311   sensitivity, and specificity of the MNA tool become more comparable to the original developers

312   [53]. Nevertheless, it's worth noting that the new cut-off value takes sensitivity and specificity to

313   a much higher value than the original cut-off points. Therefore, further studies are needed to

314   evaluate newly developed cut-off value for Ethiopian elders using combined biomarkers as the

315   golden standard. Till then the results of this study indicate the appropriateness of the tool for the

316   population under study.

317

318   Readers should take note of the following limitations while interpreting the results of our study.

319   First, dietary assessment methods were not applied and indicators for micronutrient status were

320   not assessed for the participants. Second, we only applied a single golden standard method, i.e.,

321   serum albumin, to validate the tool. The correlation between the MNA tool and BMI scores should

322   also be interpreted with caution. It is repeatedly reported that BMI is a limited application in the

323   nutritional assessment of obese individuals but otherwise are malnourished. This may have

324   influenced the result to some degree. Third, the sample size is low, and larger sample size could

325   have provided more statistically robust results. Among the strengths of this study was the inclusion

326   of the community-dwelling elderly population, and the use of a random sampling method to recruit

327   households.

328

329   Conclusion

330   This study indicated that the MNA tool was a valid and reliable tool for the Ethiopian elderly

331   population in the community setting. Future studies should explore the cost-effectiveness of MNA

332   long-form to establish if the tool is suitable for low resource settings, cost-wise.

340   MUAC =Mid-Upper Arm Circumference

341   NPV=Negative Predictive Value

342   PPV =Positive Predictive Value

343   ROC-Curve = Receiver-Operating Characteristic Curve

344

345   **Declaration**

346   **Ethics approval and consent to participate**

347

348   This study was conducted according to the guidelines laid down in the World Medical Association

349   (WMA) Declaration of Helsinki and all procedures involving research study participants were

350   reviewed and approved by Jimma University, Institute of Health, Ethical review committee (ERC).

351   The approval number of the ERC was ERB-00063/2020. Written informed consent was obtained

352   from all participants.

353

354   **Consents for publication**

355   Not applicable

356

357   **Availability of data and materials**

358   All data generated or analyzed for this study are available in manuscript.

359 **Competing of interest**

360 There are no competing interests.

361 **Funding**

362 The authors received no funding for this study from any external body.

363 **Author's contribution**

364 MU: prepared questionnaires collect data and did the analysis. Author reviewed and approved the

365 manuscript.

366 # Acknowledgements

367 We would like to Institute of health, faculty of Public Health, Jimma University. We are also

368 appreciative to the participants in the study, as well as the data collectors and supervisors.

Mini Nutritional Assessment
MNA®

Nestlé NutritionInstitute

Last name:		First name:		
Sex:	Age:	Weight, kg:	Height, cm:	Date:

Complete the screen by filling in the boxes with the appropriate numbers.
Add the numbers for the screen. If score is 11 or less, continue with the assessment to gain a Malnutrition Indicator Score.

Screening

A Has food intake declined over the past 3 months due to loss of appetite, digestive problems, chewing or swallowing difficulties?
0 = severe decrease in food intake
1 = moderate decrease in food intake
2 = no decrease in food intake ☐

B Weight loss during the last 3 months
0 = weight loss greater than 3kg (6.6lbs)
1 = does not know
2 = weight loss between 1 and 3kg (2.2 and 6.6 lbs)
3 = no weight loss ☐

C Mobility
0 = bed or chair bound
1 = able to get out of bed / chair but does not go out
2 = goes out ☐

D Has suffered psychological stress or acute disease in the past 3 months?
0 = yes   2 = no ☐

E Neuropsychological problems
0 = severe dementia or depression
1 = mild dementia
2 = no psychological problems ☐

F Body Mass Index (BMI) = weight in kg / (height in m)² ☐
0 = BMI less than 19
1 = BMI 19 to less than 21
2 = BMI 21 to less than 23
3 = BMI 23 or greater ☐

Screening score (subtotal max. 14 points) ☐☐
12-14 points: Normal nutritional status
8-11 points: At risk of malnutrition
0-7 points: Malnourished
For a more in-depth assessment, continue with questions G-R

Assessment

G Lives independently (not in nursing home or hospital)
1 = yes   0 = no ☐

H Takes more than 3 prescription drugs per day
0 = yes   1 = no ☐

I Pressure sores or skin ulcers
0 = yes   1 = no ☐

J How many full meals does the patient eat daily?
0 = 1 meal
1 = 2 meals
2 = 3 meals ☐

K Selected consumption markers for protein intake
• At least one serving of dairy products
   (milk, cheese, yoghurt) per day   yes ☐ no ☐
• Two or more servings of legumes
   or eggs per week   yes ☐ no ☐
• Meat, fish or poultry every day   yes ☐ no ☐
0.0 = if 0 or 1 yes
0.5 = if 2 yes
1.0 = if 3 yes ☐.☐

L Consumes two or more servings of fruit or vegetables per day?
0 = no   1 = yes ☐

M How much fluid (water, juice, coffee, tea, milk...) is consumed per day?
0.0 = less than 3 cups
0.5 = 3 to 5 cups
1.0 = more than 5 cups ☐.☐

N Mode of feeding
0 = unable to eat without assistance
1 = self-fed with some difficulty
2 = self-fed without any problem ☐

O Self view of nutritional status
0 = views self as being malnourished
1 = is uncertain of nutritional state
2 = views self as having no nutritional problem ☐

P In comparison with other people of the same age, how does the patient consider his / her health status?
0.0 = not as good
0.5 = does not know
1.0 = as good
2.0 = better ☐.☐

Q Mid-arm circumference (MAC) in cm
0.0 = MAC less than 21
0.5 = MAC 21 to 22
1.0 = MAC greater than 22 ☐.☐

R Calf circumference (CC) in cm
0 = CC less than 31
1 = CC 31 or greater ☐

Assessment (max. 16 points) ☐☐.☐
Screening score ☐☐.☐
Total Assessment (max. 30 points) ☐☐.☐

Malnutrition Indicator Score
24 to 30 points   ☐   Normal nutritional status
17 to 23.5 points   ☐   At risk of malnutrition
Less than 17 points   ☐   Malnourished

Characteristics of study participants elderly people aged 60 and above years

Variable	n (%)
Gender	
Male	78 (44.3%)
Female	98 (55.7%)
Age category in year	
60 – 64	61 (34.7%)
65 – 69	63 (35.8%)
70 - 74	24 (13.6%)
75 -79	23 (13.1%)
≥ 80	5 (2.8%)
	mean, SD
Age in year	67.6 (5.79)
Weight in Kg	70.7 (10.15)
Height in meters	1.7 (0.07)
Serum albumin score in g/dl	3.7 (0.60)
MNA (sum score)	20.7 (3.46)

Cronbach's alpha for MNA tool applied in the elderly population aged 60 and above years

Items	Cronbach's α if Item Deleted
Decreased food intake	0.596
Weight loss	0.559
Mobility status	0.607
Acute stress	0.633
Depression	0.599
BMI category	0.614
Living without support from other	0.591
Number of drugs per day	0.616
Ulcer on skin	0.620
Number of meals	0.619
Consumption of protein	0.589
Fruit and /or vegetable intake	0.565
Fluid intake	0.596
Feeding status	0.576
Self-perception of nutritional status	0.567
Self-perception of health status	0.526
MUAC category	0.582
CC category	0.565
Overall Cronbach's alpha	0.605

Measure of correlation, agreement and diagnostic test between MNA and Serum albumin concentration.

MNA correlation by Spearman's rho (r_s)		P value
With serum albumin concentration	0.75	0.000
With BMI classification of nutritional status	0.39	0.000
With Self-perception of nutritional status	0.51	0.000
MNA agreement with serum albumin		
Weighted kappa (95% CI)[a]	0.56(0.470,0.642)	
Weighted kappa (95% CI)[b]	0.39(0.269,0.514)	
Diagnostic accuracy		
Sensitivity	0.935	
Specificity	0.446	
PPV[c]	0.654	
NPV[d]	0.86	
Total Diagnostic accuracy	0.7045	

2   [a] *Malnutrition, risk of malnutrition, well-nourished;*

3   [b] *Malnutrition and risk of malnutrition, well-nourished*

4   [c] *Positive predictive value*

5   [d] Negative predictive value

Figure 1

ROC curves of MNA tool

The ROC curves of one hundred and seventy six samples for the MNA tool as compared to serum albumin concentration of participant elderly people aged 60 and above years

AUC (95%CI): 0.927 (0.885-0.969)
