**Background:** The way humans perceive and interact with non-human animals is particular to each person, from antipathetic interactions evidenced by fear, aversion or repulsion, to empathy evidenced by feelings of affection, enchantment and interest in the animal. In this sense, herein we investigated the perception of university students about species belonging to different classes of wild vertebrates and the influence of social and educational factors. **Methods:** Data were obtained through online forms answered by 700 university students from 9 Brazilian states, 328 females and 372 males, aged between 18 and 65 years. The form had 8 sentences to be answered in relation to 17 species of wild vertebrates. The agreement level for each of these sentences was to be indicated using a five-point Likert scale. The sentences were designed to assess aesthetic, risk, utilitarian and preservation perceptions attributed to each species by students. **Results:** We found that species that students agree are useful are generally also perceived as beautiful and should be preserved. On the other hand, we found similarity between the species perceived as ugly and should not be preserved; and between the species perceived as harmful and those considered dangerous. We found a high frequency of responses regarding agreement that the animal is useful and that it should be preserved for all species. Lower-income women and students more often agree that animals are harmful. We found that perceptions of danger in relation to animals were predominantly associated with younger respondents; however, this did not lead to less support for conservation among these students, as students of all age groups agree that species should be preserved. Our results show that students' knowledge area was an important predictor associated with empathetic and antipathetic perceptions. Environmental students showed greater empathy in all analyzed categories (beauty, usefulness, harmlessness and preservation) than non-environmental students. On the other hand, students from the

exact sciences area showed greater dislike in all analyzed categories than students from other areas. We found a strong relationship between the areas (Environmental) and (Humanities, Languages and Arts) for the attitudinal factors associated with utility and preservation, suggesting a similar empathetic worldview for students in these areas.

**Conclusions:** We found that the perception directed towards wild vertebrates varies according to the gender, age and study area of the students, in addition to the taxon considered. Finally, our results indicate that negative perceptions should be taken into account in environmental education efforts, educational policies and in planning fauna conservation plans which should incorporate the most diverse audiences, and not only encompass charismatic species, but extend to animals that arouse great aversion on the part of people.

## 24 **Abstract**

25 **Background:** The way humans perceive and interact with non-human animals is particular to each  
26 person, from antipathetic interactions evidenced by fear, aversion or repulsion, to empathy  
27 evidenced by feelings of affection, enchantment and interest in the animal. In this sense, herein we  
28 investigated the perception of university students about species belonging to different classes of  
29 wild vertebrates and the influence of social and educational factors.

30 **Methods:** Data were obtained through online forms answered by 700 university students from 9  
31 Brazilian states, 328 females and 372 males, aged between 18 and 65 years. The form had 8  
32 sentences to be answered in relation to 17 species of wild vertebrates. The agreement level for  
33 each of these sentences was to be indicated using a five-point Likert scale. The sentences were  
34 designed to assess aesthetic, risk, utilitarian and preservation perceptions attributed to each species  
35 by students.

36 **Results:** We found that species that students agree are useful are generally also perceived as  
37 beautiful and should be preserved. On the other hand, we found similarity between the species

38 perceived as ugly and should not be preserved; and between the species perceived as harmful and  
39 those considered dangerous. We found a high frequency of responses regarding agreement that the  
40 animal is useful and that it should be preserved for all species. Lower-income women and students  
41 more often agree that animals are harmful. We found that perceptions of danger in relation to  
42 animals were predominantly associated with younger respondents; however, this did not lead to  
43 less support for conservation among these students, as students of all age groups agree that species  
44 should be preserved. Our results show that students' knowledge area was an important predictor  
45 associated with empathetic and antipathetic perceptions. Environmental students showed greater  
46 empathy in all analyzed categories (beauty, usefulness, harmlessness and preservation) than non-  
47 environmental students. On the other hand, students from the exact sciences area showed greater  
48 dislike in all analyzed categories than students from other areas. We found a strong relationship  
49 between the areas (Environmental) and (Humanities, Languages and Arts) for the attitudinal  
50 factors associated with utility and preservation, suggesting a similar empathetic worldview for  
51 students in these areas.

52 **Conclusions:** We found that the perception directed towards wild vertebrates varies according to  
53 the gender, age and study area of the students, in addition to the taxon considered. Finally, our  
54 results indicate that negative perceptions should be taken into account in environmental education

62

## 63 **Introduction**

64 The existing relationships between humans and non-human animals have been altered in the course  
65 of the social transformations that have taken place throughout human history (Alves et al. 2012b;  
66 Alves and Souto 2015). Naturally, these interactions vary according to the animal taxa involved  
67 and the cultural context in which human populations are inserted.

68 The vertebrate group includes taxa that stand out for providing useful products to humans, as well  
69 as species that are targets of various conflicts (GORE et al. 2006; Inskip and Zimmermann 2009;  
70 Alves 2012). The wide range of perceptions with a greater degree of aversion or greater degree of  
71 empathy of people regarding different vertebrate species influences human attitudes towards fauna  
72 (Alves et al. 2012a; Alves et al. 2010).

73 It is known, for example, that people generally have a great aversion to snakes and have negative  
74 attitudes towards these animals (Alves et al. 2009, Silva et al. 2021). Another example is sharks  
75 being stigmatized as devouring humans, a situation partly influenced by negative contributions  
76 from the media, particularly television and cinema. These circumstances make the conservation of  
77 the group have a very low popular appeal, unlike what happens with other marine animals such as  
78 turtles, dolphins and manatees (Lessa R, Santana FM, Rincon G, Gadig OBF 1999). Thus, while  
79 some species are annually culled in numbers that put their populations at risk as a way to retaliate  
80 against human-wildlife conflicts, others are used as flagship species in conservation programs  
81 (Sabino, J., & Prado 2006).

82 Formal education may have an effect on people's attitudes towards animals, indicating that a  
83 higher education level is reflected in more positive attitudes adopted by the person (Pinheiro et  
84 al.,2016). In this sense, Ceríaco (2012) indicated that people with higher education levels have  
85 fewer misconceptions about herpetofauna linked to folkloric aspects that can generate aversion,  
86 which could be explained by their greater knowledge when compared to people with low education  
87 levels.

88 In this study, we investigated the perception of university students from Northeastern Brazil about  
89 species belonging to different classes of wild vertebrates and the influence of social and  
90 educational factors on the preservation of these animals. More specifically, we verified whether:  
91 (1) students' perceptions vary according to the animal taxon (fish, amphibians, reptiles, birds and  
92 mammals); (2) the perception changes according to the social profile of the interviewees (gender,  
93 age and socioeconomic profile); and (3) university students from the Environmental area have  
94 greater empathy towards wild vertebrates compared to students from Non-Environmental Areas  
95 (Exact sciences, Humanities, Arts and Health).

## 100 **Materials & Methods**

### 101 **Study area**

102 The data for this study were obtained through sharing online forms among students from higher  
103 education institutions in northeastern Brazilian states. This region comprises an area of 1.5 million  
104 km<sup>2</sup> and extends from about 02°54' to 17°21' S and from 35° to 46°30' W, and includes nine states.  
105 It has a population of around 57 million inhabitants, representing approximately 27% of Brazil's  
106 population (IBGE, 2021).

107

### 108 **Participants**

109

110 The form was answered by students from five knowledge areas: 1) Environmental (N= 285); 2)  
111 Linguistics, Languages and Arts (N=31); 3) Exact and Technological Sciences (N= 163); 4) Health  
112 (N=107); and 5) Applied Social Sciences and Humanities (N=114). This categorization was based on  
113 the classification of the Capes 2017 Table (the most recent version available online:  
114 [http://www.capes.gov.br/avaliacao/instrumentos-de-apoio/tabela-de-areas-do-conhecimento-](http://www.capes.gov.br/avaliacao/instrumentos-de-apoio/tabela-de-areas-do-conhecimento-avaliacao)  
115 [avaliacao](http://www.capes.gov.br/avaliacao/instrumentos-de-apoio/tabela-de-areas-do-conhecimento-avaliacao)). The study obtained a favorable opinion from the Research Ethics Committee of the Health  
116 Sciences Center of the Federal University of Paraíba - CEP/CCS (Prot. No. 095/16. CAAE:  
117 54452015.5.0000.5188.)

118 Participants from each knowledge area were randomly selected from web pages of undergraduate  
119 courses on the social network Facebook, for example (Biology 2016, Civil Engineering 2016.2,  
120 Nursing 2015, Languages 2016). Data were collected after receiving consent from the students, who  
121 were previously informed about the research objectives. Responses were obtained from 700  
122 undergraduate students belonging to 61 courses from 49 institutions (18 Federal, 11 state and 20  
123 private institutions) distributed in all of the Northeast Brazilian states (Figure 1). Of the total number  
124 of respondents, 328 were women (46.9%) and 372 were men (53.1%), aged between 18 and 65 years.  
125 The questionnaires were applied from April 2016 to January 2017.

126

### 127 **Data collection**

128 Students' perceptions of wild vertebrates were assessed through the agreement level to a series of  
129 sentences that indicate greater or lesser empathy and antipathy towards each species. The sentences  
130 were related to 17 animal species, including 4 mammals (dolphin, bat, jaguar and armadillo), 4

131 birds (vulture, owl, parrot and heron), 4 reptiles (snake, lizard, turtle and alligator), 4 fish (shark,  
132 ray, tilapia and piranha) and 1 amphibian (frog). The animals were chosen considering their  
133 potential to arouse different levels of empathy or aversion in students, in addition to being  
134 commonly found in urban and/or rural areas of the study region.

135 Four categories of perception were considered, each one consisting of two antagonistic sentences:  
136 1) Aesthetic perception, measured by the sentences “*the animal is beautiful*” and “*the animal is*  
137 *ugly*”; 2) Risk perception, measured by the sentences “*the animal is dangerous*” and “*the animal*  
138 *is harmless*”; 3) Utilitarian perception, measured by the sentences “*the animal is useful*” and “*the*  
139 *animal is harmful*”; and 4) Ecological perception measured by the sentences “*the animal must be*  
140 *preserved*” and “*the animal must not be preserved*”. The empathy and aversion levels were  
141 measured according to the agreement level with each sentence, with an agreement degree ranging  
142 from 1 to 5 on the Likert scale (Strongly Disagree, Slightly Disagree, Neither Agree nor Disagree,  
143 Slightly Agree and Strongly Agree). We attributed the perception of empathy to agreement with  
144 the empathetic sentences and disagreement with the antipathetic sentences. We attributed the  
145 perception of aversion to agreement with antipathetic sentences and disagreement with empathetic  
146 sentences.

147

#### 148 **Data analysis**

149

150 Reliability analyzes of the scales used were performed considering Cronbach’s alpha as an  
151 indicator of internal consistency (Byrne 2001). The reliability test was applied to the 4 scale factors  
152 and to all factors together.

153 Next, we performed multiple factor analysis (MFA) (Husson et al. 2018) to check for similarity  
154 between the most frequent species in each perception category. MFA takes into account the fact  
155 that the data is structured into groups (herein, different species) to balance the importance of each  
156 group in the analysis. Some perception categories are then associated when the same agreement  
157 level with certain attitudes is answered for the same set of species.

158 The Mann-Whitney U test was used to test the variation in the perception of students of different  
159 genders in relation to each taxonomic group evaluated. To examine the effects of student gender,  
160 age, income and knowledge area on the level of agreement with each sentence we performed a set  
161 of cumulative link mixed model (CLMM). We used CLMM because the data of the level of

162 agreement are ordinal, ranging from 1 (completely disagree) to 5 (completely agree). We  
163 performed five different models associated with each perception category. We considered i) the  
164 perception category as a response variable; ii) student gender, age, income and knowledge area as  
165 fixed effects predictor variables; and iii) student ID as a random factor. There was no collinearity  
166 ( $p > 0.05$ ) among predictor variables. We used residual checks to verify whether our models were,  
167 in principle, suitable or not. We used the Akaike information criterion to select models of interest  
168 if  $\Delta AIC$  values  $>6$  ( $\Delta AIC$  obtained from the difference between a null and complete model AIC  
169 values; Harrison et al., 2018; Richards, 2008). All analyses were performed in R ver. 3.5.3 (R  
170 Development Core Team, 2019) CLMM were based on the ordinal package (Christensen, 2019)  
171 and MFAs were based on the *FactoMineR* (Husson et al 2018).

172

173

174

## 175 **Results**

### 176 **Similarities between species in different Perception categories**

177

178 We found that species that students agree are useful are generally also perceived as beautiful and  
179 should be preserved. On the other hand, we found similarity between the species perceived as ugly  
180 and that should not be preserved; as well as between species perceived as harmful, and those  
181 considered dangerous (Fig 2, supplementary material Table 1). The first dimension ( $Dim_1$ ) of the  
182 MFA accounted for 35.8% of the variability in attitude categories across different species (Fig.  
183 3a). The items beautiful, ugly and harmful contributed to 21%, 20% and 18% of the variance  
184 explained by  $Dim_1$ , respectively (Fig. 2b). The second MFA dimension ( $Dim_2$ ) explained 18.5%  
185 of the variance with harmless and dangerous explaining most of the variance (34% and 31%,  
186 respectively) (Fig. 2c). We found a high frequency of responses regarding the agreement that the  
187 animal is useful and that it should be preserved for all species (Figs 3A and G). In addition, most  
188 students disagreed that the species should not be preserved (Fig 3H). Larger animals, such as  
189 jaguars, dolphins, macaws, turtles and sharks comprise the animals most frequently perceived as  
190 beautiful (Fig 3C); while piranhas, vultures, bats and frogs are generally perceived as ugly (Fig  
191 3D). Species perceived as harmless are dispersed in all categories (Fig 3E), and therefore the axis  
192 related to the harmless category did not appear close to the axes associated with other categories

193 in the MFA analysis (Fig 2). Snake, piranha and alligator make up the species most perceived as  
194 both dangerous and harmful (Fig 3B and F).

195

### 196 **Influence of socioeconomic factors on aesthetic perceptions of wild vertebrates**

197

198 We found a trend that women agree more often than men that animals are “beautiful” and less  
199 often that they are ugly, but this difference between genders was not significant (Table 1). When  
200 dividing the species into taxonomic groups, we only observed differences in perceptions between  
201 genus for mammals. In this case, we found that women more often agreed that the mammal species  
202 presented are beautiful, which denotes empathy ( $W=21579$ ;  $p=0.01$ ). On the other hand, men more  
203 often agreed that these species are ugly, indicating dislike ( $W= 16158$ ;  $p= 0.01$ ). There was no  
204 statistically significant variation in relation to the aesthetic category for the other taxa. The  
205 variation in the age group and income of the interviewees did not interfere in the aesthetic  
206 preference of the animals ( $p> 0.05$ ). Students from all areas when compared to students from  
207 environmental areas significantly perceive that the analyzed animals are uglier (Table 1).

208

### 209 **Effect of socioeconomic factors on risk perceptions**

210

211 Age showed an effect on students’ aversion, with younger students showing a greater tendency to  
212 fear, confirmed by the item “Dangerous” when compared to older students who attributed the  
213 perception that animals are more “harmless” with greater frequency. We found no significant  
214 difference between income and gender regarding risk factors (Table 2). However, analysis by  
215 taxonomic group showed that male respondents were less likely to have aversions to reptiles than  
216 females. In turn, females more frequently attributed “Dangerous” to animals in this group  
217 ( $W=15614$ ;  $p=0.01$ ), to the detriment of animals from the other taxonomic groups analyzed.  
218 Therefore, we did not obtain significant variation in relation to the other taxa. Regarding the  
219 knowledge area, students from all other areas perceive animals as more dangerous and less  
220 harmless when compared to students from the environmental area.

221

### 222 **Effect of socioeconomic factors on utilitarianism perceptions attributed to taxa**

223

224 There was an influence of gender and student income on the harmful category, with women and  
225 lower-income students more often agreeing that animals are harmful. Regarding the knowledge  
226 area, the agreement was significantly higher when considering the usefulness of vertebrates and

227 lower when considering their harmfulness between students of courses in the environmental area  
228 in relation to those in the areas of “Exact and Technological Sciences”, “Applied Social Sciences”  
229 and “Human Sciences”. On the other hand, we did not find a significant difference between  
230 students in the “Languages, Linguistics and Arts” area and in the “Environmental” area (Table 3).

231

### 232 **Influence of socioeconomic factors on preservation perceptions**

233

234 Our results showed that it was generally possible to perceive that the university students  
235 interviewed support the preservation of the evaluated organisms (median = 4.90; interquartile  
236 range = 4.70 to 5.0). We found that the agreement regarding the preservation of wild vertebrates  
237 is significantly higher among students of courses in the Environmental area in relation to those in  
238 the Exact and Technological Sciences area, followed by students of the Applied Social Sciences  
239 and Humanities area; and finally, by Health. On the other hand, we found no significant difference  
240 between students in the Languages, Linguistics and Arts area and in the Environmental area  
241 regarding the preservation of wild vertebrates.

242 We also observed that agreement of the “do not preserve” category was significantly lower among  
243 students from courses in the Environmental area in relation to those in the areas of Exact and  
244 Technological Sciences, Applied Social Sciences and Humanities. Older and lower-income  
245 students more often agree that species should not be preserved (Table 4).

246

### 247 **Cronbach’s Alpha for Scale Factors**

248

249 The factor analysis results indicated that the eight items used in our scale were used to measure  
250 four factors: Aesthetics, Utility, Risk and Preservation. Cronbach’s alpha coefficient for the  
251 **Aesthetic Factor** was ( $\alpha = 0.94$ ); we obtained ( $\alpha = 0.79$ ) for the **Risk factor**, ( $\alpha = 0.81$ ) for the  
252 **Preservation factor**, while we found a much lower value ( $\alpha = 0.17$ ) for the **Utility factor**.  
253 Cronbach’s alpha coefficient for the entire instrument was ( $\alpha = 0.73$ ). This indicates that the  
254 questionnaire showed a good degree of reliability (Nunnally 1978; Prokop, Tolarovičová *et al.*  
255 2010; Prokop *et al.* 2009).

256

257

## 258 Discussion

259 We found that factors such as aesthetics, utilitarian potential and the risk associated with animals  
260 are strong influencers of perceptions and attitudes towards the preservation of wild vertebrates.  
261 These results reinforce previous studies carried out with students of different education levels  
262 (Kidd & Kidd 1990; Prokop et al. 2009a; Prokop et al. 2009; Campos et al. 2012), from  
263 kindergarten (Alves et al. 2014; Borgi and Cirulli 2015; Kubiak 2012) to University.

264 It is known that the perception directed to animals varies according to taxa. Our results reinforce  
265 this trend, with a great variation in the perception of the students interviewed in relation to the  
266 different animals analyzed. Among the animals considered the most beautiful are large,  
267 charismatic and iconic mammals such as the jaguar and dolphin, and one of the most popular wild  
268 birds as pets in Brazil and in the world: the parrot (Alves et al. 2013; Fernandes-Ferreira et al.  
269 2012b; Roldán-Clarà et al. 2014). Charismatic wild vertebrates that are often the target of  
270 conservation campaigns (Barney et al. 2005; Schlegel and Rupf 2010) are also favored in relation  
271 to society's perception of fauna, and this situation was also observed in our study.

272 In another perspective, some authors suggest that humans empathize with phylogenetically closer  
273 animals, for example those exhibiting, physical, behavioral or cognitive similarities with humans  
274 (Herzog & Burghardt 1988; Miralles et al. 2019), therefore mammals would also benefit in this  
275 aspect due to the potential to awaken anthropomorphic projections (human emotions or intentions  
276 to non-human entities) (Miralles et al. 2019). On the other hand, among the taxa with the lowest  
277 scores in relation to aesthetics are animals such as piranha, vultures, frogs and bats, which are  
278 associated with risks to humans or negative beliefs. For example, bats are the target of legends and  
279 tales that encourage people to dislike these animals in Brazil (Rego et al. 2015), being considered  
280 uncharismatic for the general population and the potential ecological benefits of these animals are  
281 rarely disclosed.

282 Aesthetically attractive species also received greater support for preservation and were more  
283 perceived as useful by respondents. Other studies (Pinho et al. 2014; Gunnthorsdottir 2001) have  
284 also reported greater public support for species deemed most attractive. Our data also revealed that  
285 students of both genders valued the aesthetics of organisms, but with women considering mammals  
286 more beautiful and reptiles more dangerous than other taxa. For Kaltenborn et al. (2006), gender  
287 exerts a significant influence on affinity levels towards animals. In this sense, some works such as  
288 those by (Kellert 1989; Williams et al. 2002; Zinn and Pierce 2002) suggest that women have

289 higher levels of support for species protection than men. However, it is noteworthy that this affinity  
290 may vary according to the taxon considered, as found herein.

291 The results obtained by Czech et al. (1998) reinforce this situation, suggesting that mammals, birds  
292 and fish are part of a distinctly more positive social construction, and thus were identified as more  
293 “advantaged” than reptiles (excluding turtles). However, in the case of reptiles, despite the  
294 aversion that people generally have towards some animals of this group such as snakes (Alves et  
295 al. 2012a; Alves et al. 2014; Alves et al. 2012c), there are extremely charismatic species, such as  
296 turtles; they are characterized by docility and are often the target of conservation campaigns, which  
297 reflects people’s positive view of these chelonians, as our results indicate, which point to the  
298 “turtle” with greater preservation appeal than other reptiles.

299 Like aesthetics, the usefulness of animals tends to be a factor which positively influences their  
300 perception by people. Species of practical utility in human life, whether for providing products  
301 used by people for nutrition or as part of their leisure activities tend to be more valued. In fact, the  
302 animal that obtained the highest score in the “useful” item was a fish (tilapia), widely consumed  
303 as food in Brazil. However, animals such as jaguars, vultures and frogs also achieved high scores,  
304 suggesting that students recognize the value of these animals in the environment. This may indicate  
305 that higher education students recognize the ecological role of animals in general, regardless of  
306 whether the animals in question are a source of products used directly by humans or not. Similar  
307 results were found by other authors, such as Kellert and Berry (1980), Bjerke and Ost Dahl (2004)  
308 and Schlegel and Rupf (2010), who found coherence between higher education levels and positive  
309 perceptions of fauna.

310 If useful animals generate greater empathy in people, animals that pose risks and are targets of  
311 conflict with humans, in turn, tend to arouse more aversion. This is the case of snakes in Brazil,  
312 which, as some works point out, are the target of aversion and fear on the part of people generally  
313 due to the risk they pose to human lives and their domestic animals (Alves et al. 2012a; Alves et  
314 al. 2012c; Fernandes-Ferreira et al. 2013; Mendonça et al. 2014). Additionally, snakes inspire  
315 many myths, proverbs and stories that are transmitted orally and that place these animals as beings  
316 associated with evil and that influence the way local people relate to these animals, generally  
317 provoking negative attitudes on the part of people (Fernandes-Ferreira et al. 2013; Mendonça et  
318 al. 2011; Mendonça et al. 2014). Thus, snakes were the animals which generally had the highest  
319 scores on the harmful item among the students interviewed. In addition to snakes, animals such as

320 piranhas, alligators and sharks, which can be seen as a potential risk to humans, were recognized  
321 as more harmful (Fig.3).

322 Our data revealed that lower-income students more often agree that animals are harmful. This  
323 result can be associated with the fact that the economic impact generated by the attack of wild  
324 animals on crops and livestock is more significant for low-income people than for those with  
325 higher incomes. In particular, among the animals that were shown to arouse higher perceptions of  
326 danger in the students interviewed, some of them such as sharks, jaguars, alligators and snakes are  
327 known to evoke fear because they are predominantly large, with physical characteristics that  
328 arouse threat or because they are venomous (Staňková et al 2021; Silva et al 2021). A greater  
329 perception of fear and harm by smaller vertebrates was associated with piranha, which may  
330 indicate a direct threat link to humans given that their attack can generate extensive tissue loss and  
331 bleeding (Haddad and Sazima 2003). Piranhas are quite small compared to sharks (for example),  
332 but both fish stand out in our study as the species with the highest fear perception scores. Both  
333 species are carnivorous, with sharp teeth and often referred to as dangerous animals by the media,  
334 thereby constituting characteristics which reinforce the perception of fear in humans. It should be  
335 noted that other animals such as bats and snakes, for example, are also associated with negative  
336 aspects by the media, enhancing society's negative perception of them.

337 Negative perceptions directed towards animals imply less support for their preservation, and, as  
338 we have pointed out in our study, may result from social factors such as gender, income, age,  
339 superstitions and myths, formal education and education area. Reinforcing previous research, our  
340 results suggest that human beliefs which negatively impact animals are randomly pervasive in the  
341 population, regardless of age, culture, gender (Mintzes & Wandersee 1998), or specialized study  
342 area (Prokop & Kubiátko 2009). The increase in knowledge about the ecological role of less  
343 attractive animals in human vision could make it possible to improve their respective images,  
344 reinforcing the need to create environmental policies that include less aesthetically attractive  
345 organisms, as well as flagship species.

346 Corroborating our results, previous studies have found that younger people with higher education  
347 are often more associated with positive perceptions of wildlife (Dressel et al. 2015; Kellert 1980;  
348 Smith et al. 2014; Vaske et al. 2011). However, this has not led to less support for conservation  
349 among older students, as students of all age groups agree with high frequency that species should  
350 be preserved.

351 Antipathetic perceptions towards animals are also widespread in the population, with greater  
352 aversion to animals that pose a risk to humans and are the target of conflicts with them. Our results  
353 also showed that the knowledge field of university students has an influence on targeted  
354 perceptions of vertebrate preservation. Thus, it can be seen that there is a tendency towards more  
355 favorable perceptions of preservation among students of courses with content associated with  
356 nature and with greater contact with educational-environmental activities. Several studies point  
357 out that having contact with nature and developing an emotional bond with natural elements are  
358 determining factors for a preservationist perception (Collado et al. 2013, Collado & Corraliza  
359 2015, Duerden & Witt 2010), and attitudes that support biodiversity will be consolidated through  
360 concrete experiences with nature (Turpie, 2003). In this context, since our results showed  
361 similarity in the preservation perception between students of “Languages, Linguistics and Arts”  
362 and the “Environmental” area, it is assumed that a greater appreciation for biodiversity may also  
363 result from intrinsic motivations of the student’s own subject, as they seek to study something for  
364 which they are already close to. On the other hand, direct contact with the urbanized environment  
365 and the appropriation of technologies, whether in the home or work environment, may imply less  
366 contact between people and nature, both from an affective and preservation point of view (Zhang  
367 et al. 2014). This situation may explain the greater antipathy towards the conservation of fauna  
368 observed among university students of the courses in the Exact and Technological Sciences area,  
369 therefore configuring a different connection link with the fauna than that established among the  
370 students of the Environmental area.

371

372

373

## 374 **Conclusions**

375 Our results indicate that the perception directed towards wild vertebrates varies according to the  
376 students’ gender, age and study area, in addition to the taxon considered, implying more or less  
377 favorable perceptions of animal preservation. Animals with utilitarian value and components of  
378 the so-called charismatic megafauna tend to have more preservation appeal, to the detriment of  
379 animals which cause aversion and are the target of constant conflicts with humans, such as snakes  
380 and bats, which confirms our hypothesis that there is variation of perception directed to vertebrates  
381 according to the analyzed taxon. It is therefore evident that this whole scenario, which influences  
382 negative perceptions, must be taken into account in elaborating environmental education and fauna

383 conservation projects, which must incorporate the most diverse audiences, and not only encompass  
384 charismatic species, but also extend to animals that arouse great aversion on the part of people.

385

386

387

## 388 **Acknowledgements**

389 We are especially grateful to university students from different institutions who supported us in  
390 collecting data and shared their knowledge about wild vertebrates with us. Without them, this work  
391 would not be possible. We thank LECOPSI - Laboratory of Behavioral Ecology and  
392 Psychobiology - UFPB for the support with access to the use of the laboratory's online software  
393 during the construction and execution of the study and for the guidance in the data tabulation.

# Figure 1

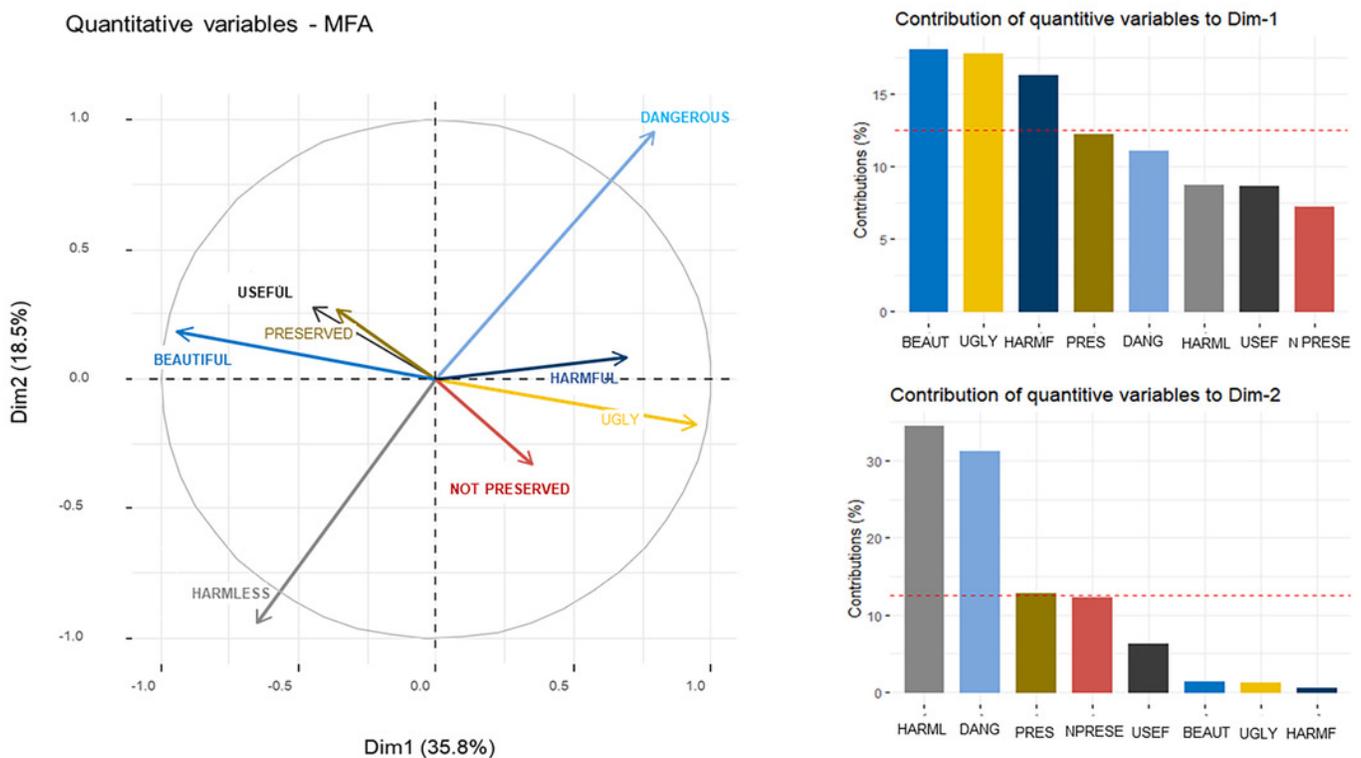

States of location of respondents, Number of institutions included in the research by state (N=49). Number of students interviewed by state (N=700)

## Figure 2

Compositional similarity of sentences of perceptions of empathy and antipathy obtained from (a) of the MFA.

Contributions of each perception to (b) the first (Dim1) and (c) the second dimension (Dim2). The red dotted line indicates the percentage that would be obtained if all factors contributed equally to the overall variance.

## Figure 3

Number of responses for each level of agreement associated with the perception categories Aesthetics (A and B), Utilitarian (C and D), Risk (E and F) and Preservation (G and H) among wild vertebrates.
