28 Short title: MEG3 Genotypes in Asthma

29

# Abstract

**Background:** Asthma is the most common chronic inflammatory airway disease worldwide. Asthma is a complex disease whose exact etiologic mechanisms remain elusive; however, it is increasingly evident that genetic factors play essential roles in the development of asthma. The purpose of this study is to identify novel genetic susceptibility loci for asthma in Taiwanese. We selected a well-studied long non-coding RNA (lncRNA), *MEG3*, which is involved in multiple cellular functions and whose expression has been associated with asthma. We hypothesize that genetic variants in *MEG3* may influence the risk of asthma.

**Methods:** We genotyped four single nucleotide polymorphisms (SNPs) in *MEG3*, rs7158663, rs3087918, rs11160608, and rs4081134, in 198 patients with asthma and 453 healthy controls and measured serum *MEG3* expression level in a subset of controls.

**Results:** The variant AG and AA genotypes of *MEG3* rs7158663 were significantly over-represented in the patients compared to the controls ( $P = 0.0024$ ). In logistic regression analyses, compared with the wild-type GG genotype, the heterozygous variant genotype (AG) was associated with a 1.62-fold [95% confidence interval (CI) = 1.18-2.32,  $P = 0.0093$ ] increased risk and the homozygous variant genotype (AA) conferred a 2.68-fold (95% CI = 1.52-4.83,  $P = 0.003$ ) increased risk of asthma. The allelic test showed the A allele was associated with a 1.63-fold increased

risk of asthma (95% CI = 1.25-2.07,  $P = 0.0004$ ). The AG plus AA genotypes were also associated with severe symptoms ( $P = 0.0148$ ). Furthermore, the AG and AA genotype carriers had lower serum MEG3 expression level than the GG genotype carriers, consistent with the reported downregulation of MEG3 in asthma patients.

**Conclusion:** *MEG3* SNP rs7158663 is a genetic susceptibility locus for asthma in Taiwanese. Individuals carrying the variant genotypes have lower serum MEG3 level and are at increased risks of asthma and severe symptoms.

# 61 Introduction

62 Asthma is the most common chronic lung disease characterized by airway  
 63 obstruction, airway inflammation, and airway hyperresponsiveness. Globally,  
 64 approximately 300 million people are affected by asthma annually, and its  
 65 prevalence is continuously increasing (*Mattiuzzi & Lippi, 2020; Global Initiative for*  
 66 *Asthma, 2022*). There are large geographical differences in the incidence of asthma  
 67 and developed countries generally have higher incidences of asthma than developing  
 68 countries largely due to higher environmental exposures including smog and air  
 69 particles (*Mulgirigama et al., 2019*). Asthma is a complex disease whose etiology  
 70 involves both environmental exposures and genetic susceptibility. It was estimated  
 71 that asthma has a genetic heritability of up to 60%–80% (*Ober & Yao, 2011;*  
 72 *Kabesch & Tost, 2020; Bonnelykke & Ober, 2016*). An animal disease model  
 73 mimicking human asthma suggested that approximately 200 genes may contribute  
 74 to the etiology of asthma (*Temesi et al., 2014*). Candidate gene studies focusing on  
 75 biologically relevant genes such as inflammatory and immunological genes and  
 76 genome-wide association studies (GWAS) have identified a number of genetic  
 77 susceptibility loci for asthma (*Bonnelykke & Ober, 2016; Liu et al., 2022; Shen et*  
 78 *al., 2017; Hsia et al., 2015; García-Sánchez et al., 2015; Shi et al., 2022; Ranjbar*  
 79 *et al. 2022*). However, the identified asthma susceptibility loci to date only explain  
 80 a small portion of the genetic heritability of asthma and additional genetic

81 susceptibility loci to asthma remains to be uncovered.

82 Long noncoding RNAs (lncRNAs) are defined as RNAs longer than 200  
83 nucleotides that are not translated into functional proteins (*Orom & Shiekhattar,*  
84 *2013*). In recent years, it has been increasingly evident that lncRNAs are important  
85 regulators of gene expression in diverse cellular processes, thus are essential for  
86 maintaining normal physiology, and are often dysregulated in various diseases  
87 including asthma (*Melissari et al. 2016; Rafiee et al. 2018; Statello et al. 2021;*  
88 *Gysens et al., 2022; Chen & Deng, 2022*). A number of studies have compared the  
89 expression of different lncRNAs in blood cells between asthma patients and healthy  
90 controls and identified several differentially expressed lncRNAs (*Tsitsiou et al.,*  
91 *2012; Booton & Lindsay, 2014; Feng et al., 2020; Chen & Deng, 2022*), among  
92 which maternally expressed gene 3 (MEG3) is of particular interest. The *MEG3* gene  
93 is located in chromosome 14q32.3 and encodes a lncRNA of approximately 1.6 kb  
94 (Zhang et al., 2010). MEG3 is abundantly expressed in normal tissues and plays an  
95 essential role in cell growth and organ development (Da Rocha et al., 2008). Earlier  
96 studies found reduced expression of MEG3 in the circulating CD8<sup>+</sup> T cells of  
97 patients with severe asthma (*Tsitsiou et al., 2012; Booton & Lindsay, 2014*). A recent  
98 study (*Feng et al., 2020*) reported that serum MEG3 level was significantly lower in  
99 asthma patients than in healthy controls and was the lowest in the most severe asthma  
100 patients. Furthermore, there was a significant inverse correlation between serum

MEG3 expression and the course of asthma ( $r = -0.666$ ,  $P < 0.001$ ) (Feng et al., 2020). *In vitro* experiments also provide indirect evidence supporting that low MEG3 expression is linked to asthma development: treating human bronchial epithelial cells with cigarette smoke condensate (Hu et al. 2009) or an environmental carcinogen nickel (Zhou et al., 2017) caused marked downregulation of MEG3 expression.

Given that aberrant MEG3 expression is linked to asthma development, we hypothesize that genetic variants that affect MEG3 expression may be associated with the risk of developing asthma. Several SNPs in MEG3 have been reported in literature that may affect MEG3 expression and influence the risks of various diseases including inflammatory response, diabetes, stroke, and cancer (Wallace, 2010; Han et al., 2018; Ghaedi et al., 2018; Ghafouri-Fard & Taheri, 2019; Gao et al., 2021; Zhu et al., 2021; Zhong et al., 2022). We therefore perform the first study to evaluate the associations of SNPs in MEG3 with the risks of asthma using a case control study design. In addition, we determine whether the selected SNPs influence the expression level of MEG3 in serum samples and provide strong genotype-gene expression correlation that explains the observed significant association between SNPs and asthma risk.

## Materials & Methods

# **Recruitment of asthmatic cases and non-asthmatic healthy controls**

A total of 198 patients with asthma and 453 non-asthmatic healthy controls were recruited from China Medical University Hospital (CMUH) as previously described (Hsia *et al.*, 2015; Li *et al.*, 2021). The diagnosis of asthma was based on the following inclusion criteria: 1) more than two or three episodes of wheezing and shortness of breath during the past year; 2) diagnosis of asthma by pulmonologists together with the demonstration of reversible and variable airflow obstruction by spirometry; 3) symptoms; and 4) prescription of medications for asthma. No children were recruited (the youngest being 25 years old) and there was no sex restriction. The controls were selected by frequency-matching to cases by age and sex after initial random sampling from the Health Examination Cohort of CMUH. The inclusion criteria for controls were: 1) no past or present physician's diagnosis of asthma and other pulmonary diseases; 2) no history of wheezing, shortness of breath, or other symptoms of allergic diseases such as nasal and skin symptoms; 3) no use of medications for asthma; 4) absence of first-degree relatives with a history of asthma; and 5) older than 25 years. Those with chronic inflammatory responses, diabetes, stroke and cancer were also excluded for both cases and controls, the flow chart of participant recruitment scheme was shown in Figure 1. The symptom severity for each asthma case was verified by two experienced pulmonologists according to the Global Initiative for Asthma (GINA) guidelines (*Global Initiative*

for *Asthma*, 2022). Specifically, symptom severities were classified into 4 groups based on the treatment to control the symptoms and exacerbations. Group 1 (mildest): treated with as-needed inhaled corticosteroid (ICS)-formoterol alone; Group 2, treated with low-intensity maintenance controller treatment of ICS-formoterol, leukotriene receptor antagonists or chromones; Group 3, treated with low dose ICS-long acting  $\beta$ 2 agonist (LABA); and Group 4, treated (severest) with high dose ICS-LABA. Peripheral blood was collected from all subjects and genomic DNA was extracted and stored until genotyping (Yang *et al.*, 2017b). This study was approved by the Research Ethics Committee of the China Medical University Hospital (CMUH106-REC1-004). All protocols were conducted in accordance with relevant guidelines. All patients provided written informed consent at the time of recruitment.

### Genotyping methodology for *MEG3* genotypes

We selected 4 SNPs (Figure 2) that were either correlated with *MEG3* expression or associated with other diseases in previous publications (Han *et al.*, 2018; Ghaedi *et al.*, 2018; Ghafouri-Fard & Taheri, 2019; Gao *et al.*, 2021; Zhu *et al.*, 2021; Zhong *et al.*, 2022). The *MEG3* rs7158663, rs3087918, rs11160608, and rs4081134 genotypes were determined using TaqMan assay with an ABI 7500 Real-Time PCR System (Applied Biosystems, Foster City, CA, USA) as previously described (Pei

*et al.*, 2022).

### Transcriptional expression of MEG3 in serum

To evaluate the correlation between MEG3 RNA expression and *MEG3* rs7158663 genotype, 46 serum samples were randomly selected from the controls and subjected to extraction of total RNA using TRIzol Reagent (Invitrogen, Carlsbad, CA, USA). They were randomly selected from the pool of controls, and there were no significant differences between these samples and the remaining controls in terms of age, sex and smoking status. The expression levels of MEG3 were measured by real-time quantitative reverse transcription-PCR (RT-PCR) using an FTC-3000 real-time PCR instrument series (Funglyn Biotech Inc., Canada). GAPDH was used as an internal control (*Liao et al.*, 2020; *Huang et al.*, 2018). MEG3 primers were purchased from Qiagen (UniGene No. Hs.654863, Catalog No. 4331182, LPH02974A-200). For GAPDH, the forward and reverse primers were 5'-GAAATCCCATCACCATCTTCCAGG-3' and 5'-GAGCCCCAGCCTTCTCCATG-3', respectively. During the analysis, the levels of MEG3 RNA were normalized to those of GAPDH expression. Each sample was measured three times.

### Statistical methodology

The goodness-of-fit chi-square test was used to examine the fitness of the Hardy-Weinberg equilibrium in the control group. The *Student's t*-test was used to examine the differential distributions of age between the case and control groups. Pearson's chi-squared test was used to examine the differential distribution of various *MEG3* genotypes and the interaction between *MEG3* genotypes and symptom severity. The association of *MEG3* genotypes with asthma risk was evaluated by calculating the odds ratios (ORs) and the corresponding 95% confidence intervals (CIs) using multivariable logistic regression analyses adjusting for age, sex, and smoking status. The differential expression levels of *MEG3* shown in Figure 3 were evaluated with unpaired *Student's t*-test. The statistical significance level was set at  $P < 0.05$ .

## Results

### Demographics of asthmatic and non-asthmatic subjects

The age, sex, smoking, and clinical characteristics such as pulmonary function and symptom severity of the 198 patients and 453 controls are shown in Table 1. The patients and controls were frequency-matched on age and sex ( $P = 0.2972$  and  $0.9956$ , respectively). There were slightly more ever-smokers among cases than controls (29.8% vs. 28%), but the difference was not statistically significant ( $P = 0.7161$ ). Regarding pulmonary function, the average ratio of forced expiratory volume in the first second to forced vital capacity (FEV1/FVC, %) and the percentage of predicted FEV1 (FEV1%) was significantly lower in the asthmatic

group than in the control group (both  $P < 0.0001$ ). The percentage of patients within symptom severity group 1 (mild), 2, 3, and 4 (severe) was 30.3, 32.8, 17.2, and 19.7, respectively (Table 1).

### **Associations of *MEG3* genotypes with asthma risk**

The distributions of the genotypes of *MEG3* rs7158663, rs3087918, rs11160608, and rs4081134 in the cases and controls are shown in Table 2. First, the genotype frequencies of the four SNPs in the control group all fit well with Hardy-Weinberg equilibrium (all  $P > 0.05$ ). Second, the genotype frequencies of rs7158663 were differentially distributed between the cases and controls with the heterozygous variant AG and homozygous variant AA genotypes over-represented in the cases compared to controls (44.5% vs. 36.4% for AG and 12.1% vs. 6.6% for AA genotype). In logistic regression analyses, the AG and AA genotypes were both associated with increased risks of asthma (adjusted ORs = 1.62 and 2.68, 95% CIs = 1.18-2.32 and 1.52-4.83,  $P = 0.0093$  and  $0.0030$ , respectively) compared with the wild-type GG genotype. In the dominant model, individuals carrying the variant genotypes (AG+AA) exhibited a 1.75-fold increased risk of asthma (adjusted OR = 1.75, 95% CI = 1.29-2.48,  $P = 0.0015$ ). The other three SNPs, rs3087918, rs11160608, and rs4081134, were not significantly associated with the risks of asthma (Table 2).

222

# 223 **Allelic frequency distribution analysis**

224 The allelic frequencies of rs7158663, rs3087918, rs11160608, and rs4081134 SNPs  
225 among cases and controls are shown in Table 3. Consistent with the findings in Table  
226 2, individuals with the variant A allele at rs7158663 were at a higher risk of asthma  
227 than those with the wild-type G allele after adjusting for age, sex, and smoking status  
228 (adjusted OR = 1.63, 95% CI = 1.25-2.07,  $P = 0.0004$ ). In contrast, the variant alleles  
229 of the other three SNPs were not associated with asthma risks (Table 3).

230

# 231 ***MEG3* rs7158663 genotypes are associated with the severity of asthma symptom**

232 We then analyzed the distributions of *MEG3* genotypes among asthma patients  
233 within different symptom groups (Table 4). The variants genotypes (AG or AA) of  
234 rs7158663 were over-represented in patients with more severe symptoms: the  
235 frequencies of the variant genotypes and wild-type (GG) genotype was 35% and  
236 65% in patients with the mildest symptom (Group 1), 44.6% and 55.4% in Group 2,  
237 55.9% and 44.1% in Group 3, and 69.2% and 30.8%, respectively, in patients with  
238 the most severe symptom (Group 4) ( $P = 0.0148$ ) (Table 4). In contrast, the other  
239 three SNPs were not associated with asthma symptoms.

240

241 To determine whether the association of rs7158663 with asthma differs between

patients with mild and severe symptoms, we next performed stratified analyses. To increase statistical power, we combined the two milder symptom groups and two severer symptom groups. As shown in Table 5, the association of the rs7158664 variant genotypes with asthma risk was only significant in patients with severer symptoms (adjusted OR=2.48, 95% CI=1.44-4.26,  $P = 0.0024$ ), but not in patients with milder symptoms (adjusted OR = 0.91, 95% CI=0.61-1.43,  $P = 0.6115$ ) (Table 5).

# **The variant genotypes of rs7158663 correlated with lower serum MEG3 level**

Since *MEG3* rs7158663 variant genotypes are associated with increased asthma risks, and asthma patients have lower serum MEG3 level than controls (Feng et al., 2020), we next determine whether there is a correlation between rs7158663 genotypes and serum MEG3 level. We randomly selected 46 healthy controls and measured serum MEG3 expression level by quantitative PCR (one sample was somehow technically undetectable). Compared to the wild-type GG genotype carriers, the serum MEG3 expression level was significantly lower for the GA genotype carriers ( $P < 0.0001$ ) and the lowest in AA genotype carriers ( $P < 0.0001$  vs. GG genotype carriers and  $P = 0.0081$  vs. AG genotype carriers) (Figure 3).

# **Discussion**

In the current study, we found significant associations between *MEG3* rs7158663 SNP and the risk of asthma and symptom severity. Specifically, the variant genotypes (AG and AA) of rs7158663 were associated with increased risks of asthma and severe asthma symptoms. The variant genotype carriers had significantly lower serum *MEG3* expression (Figure 3), consistent with prior reports of downregulation of *MEG3* expression in asthma patients and providing biological explanation for the observed associations between variant genotypes and increased asthma risks. To our knowledge, the present study is the first to report the associations of *MEG3* genotypes with asthma risk and symptom severity.

*MEG3* is a lncRNA that is abundantly expressed in most normal tissues but downregulated in a variety of tumor tissues including lung cancer (*Ghafouri-Fard & Taheri, 2019*). There have been strong evidences supporting that *MEG3* plays a role in asthma development. An early study compared the profile of lncRNA expression in circulating CD8<sup>+</sup> T cells from asthma patients and healthy controls and found *MEG3* expression was significantly lower in patients with severe asthma than healthy controls (*Tsitsiou et al., 2012*). A recent study (Feng et al., 2020) compared serum *MEG3* expression level in 119 asthma patients and 125 healthy controls and found significantly lower serum *MEG3* level in asthma patients than in controls and the expression level was the lowest in mixed granulocytic asthma (the subtype with

the most severe symptoms). Furthermore, serum MEG3 level was negatively correlated with the course of disease ( $r = -0.666$ ,  $P < 0.001$ ). Logistic regression analysis showed that inflammatory phenotype, the course of disease, and serum MEG3 level were independent prognostic factors for the recurrence of asthma (Feng et al., 2020). Supporting these direct evidences of human studies linking low MEG3 expression to asthma development, an early *in vitro* experiment tested the effects of cigarette smoke condensate (CSC) treatment on gene expression of human bronchial epithelial cells (HBEC) and found MEG3 was down-regulated in CSC-treated cells (Hu et al., 2009). Another *in vitro* study showed MEG3 expression was suppressed upon nickel (an environmental toxigenic molecule) treatment of HBEC (Zhou et al., 2020). All these evidences suggest that abundant MEG3 expression is important to maintain normal lung function and physiology, whereas reduced MEG3 expression favors proliferation and promotes the pathogenesis of common lung diseases such as asthma and lung cancer.

Our findings in this current study supports the notion that reduced MEG3 expression favors asthma development. We found the variant genotypes (AG and AA) of *MEG3* rs7158663 were associated with increased risks of asthma and severe symptoms. Furthermore, the variant genotypes of rs7158663 correlated with lower serum MEG3 expression. The rs7158663 genotypes-MEG3 expression-asthma

relationship is therefore biologically meaningful and plausible. Consistent with our rs7158663 genotype-MEG3 expression correlation, a previous study also found the variant A allele of rs7158663 was associated with significantly decreased serum MEG3 level compared to the wild type G allele ( $P < 0.0001$ ) (Ali et al., 2020).

The exact biological mechanisms underlying the roles of MEG3 in asthma pathogenesis remains unclear. MEG3 is a multi-faceted molecule involved in many microRNA and protein interactions, signal pathways, and cellular processes (Ghafouri-Fard & Taheri, 2019; Chen & Deng, 2022). MEG3 activates transcription factor and tumor suppressor TP53 by stabilizing TP53 protein and/or augmenting its transcriptional activity, thereby induces TP53-dependent target gene expression and inhibits cell growth (Zhou et al., 2007; Ghafouri-Fard & Taheri, 2019). MEG3 interacts with the polycomb repressive complex 2 (PRC2), which catalyzes the methylation of histone H3 lysine 27 (H3K27) and functions as a key epigenetic regulator for normal development (Simon & Kingston, 2013). MEG3 interacts with PRC2 and its cofactor JARID2 to regulate TGF- $\beta$  signaling pathway genes (Kaneko, et al., 2014; Mondal et al., 2019). MEG3 also contributes to the regulation of several other important cellular signaling pathways, including PI3K/AKT/mTOR, Wnt/ $\beta$ -catenin, JAK/STAT, and Notch, and these pathways have been implicated in asthma (Wang et al., 2014; Ghafouri-Fard & Taheri, 2019; Athari 2019; Zhao et al., 2020).

More recently, increasing studies have shown another important function of MEG3: serving as a competing endogenous RNA (ceRNA) and sponge for various miRNAs, and counteracting their regulatory effects on target genes (*Moradi et al., 2019; Li et al., 2016; Zhang et al., 2021; Li et al., 2018; Luo et al., 2021; Qiu et al., 2019; Dong et al., 2022; Sun et al., 2021; Wang et al. 2021*). In this regard, it is worth noting that MEG3 could sponge microRNA-125a-5p (*Li et al. 2016*) and miRNA-17 (*Qiu et al. 2019*) as a ceRNA, relieve their inhibition on orphan receptor  $\gamma$ t (ROR $\gamma$ t), which is a regulator of regulatory T (Treg) cells and helper T cell-17 (Th17). Mounting evidences suggest that the balance of Treg and Th17 (Treg/Th17) plays a critical role in asthma development (*Tao et al., 2015; Zhu et al., 2017; Jing et al., 2019; Zhou et al., 2022*). Therefore, the microRNA sponge effect of MEG3 may be one of the biological mechanisms responsible for the involvement of MEG3 in asthma development. Better understanding of the biology behind the roles of MEG3 in asthma warrants further investigation.

MEG3 SNPs are associated with multiple diseases including asthma, inflammatory response, diabetes, stroke, and cancer (*Wallace, 2010; Han et al., 2018; Ghaedi et al., 2018; Ghafouri-Fard & Taheri, 2019; Gao et al., 2021; Zhu et al., 2021; Zhong et al., 2022*). Pleiotropy (i.e., shared genetic predisposition loci to different human diseases and traits) is pervasive in human genome (*Sivakumaran et*

*al.*, 2011; *Pickrell et al.*, 2016; *Tian et al.*, 2022). For example, a missense SNP (rs13107325) the zinc transporter SLC39A8 influences the risks of at least 7 different diseases and genetic traits, including schizophrenia, Parkinson's disease, Crohn's disease, allergy, height, nearsightedness, and HDL (*Pickrell et al.*, 2016); and SNPs in the TERT-CLPTM1L locus have been associated with more than 12 different cancer and non-cancer diseases (*Tian et al.*, 2022).

The present study has several limitations. First, we only selected one candidate gene and the sample size was modest. Larger scale studies are needed to have a more complete understanding of the genetic susceptibility to asthma in Taiwan. Second, we had missing or incomplete information on some known environmental risk factors and lacked longitudinal data of the dynamic environmental exposures and could not perform gene-environment interaction analyses. Lastly, the mRNA levels of MEG3 are lower in asthma patients than in healthy controls (*Feng et al.*, 2020). As a common practice, we performed the genotype-expression correlation in a subset of healthy controls. It is worthwhile to validate that the variant genotypes also correlate with lower MEG expression in asthma patients.

## Conclusions

This study provides the first evidence that the variant genotypes at *MEG3* rs7158663 are associated with increased asthma risk and symptom severity. Moreover, there is a significant association between the variant genotype and lower *MEG3* expression in serum. *MEG3* rs7158663 is a novel genetic susceptibility locus for asthma.

Figure 1. The proposed flow chart of participant recruitment.

Figure 2. The map of polymorphic sites of *MEG* rs7158663, rs3087918, rs11160608, and rs4081134.

Figure 3. Correlation between *MEG3* rs7158663 genotype and *MEG3* expression in the serum of healthy controls. \*Statistically significantly different from GG genotype; # Statistically significantly different from AG genotype.

## Acknowledgments

We thank Yu-Ting Chin and Tai-Lin Huang for technical assistance in DNA extraction and serum *MEG3* measurement.

## Additional information and declarations

## Funding

This study was supported by grants from the Taichung Tzu Chi Hospital (TTCRD111-15), China Medical University Hospital, and Asia University (CMU111-ASIA-02). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

## Grant Disclosures

The following grant information was disclosed by the authors:

Taichung Tzu Chi Hospital in Taichung, Taiwan: TTCRD111-15.

China Medical University Hospital, and Asia University in Taichung, Taiwan:

CMU111-ASIA-02.

## Competing Interests

The authors declare no competing interests.

## Author Contributions

Kuo-Liang Chiu conceived and designed the experiments, analyzed the data, and approved the final draft.

Wen-Shin Chang performed the experiments, analyzed the data, and approved the final draft.

Chia-Wen Tsai performed the experiments, analyzed the data, prepared figures and tables, and approved the final draft.

Mei-Chin Mong conceived and designed the experiments, authored and reviewed drafts of the paper, and approved the final draft.

Te-Chun Hsia analyzed the data, authored and reviewed drafts of the paper, and approved the final draft.

Da-Tian Bau conceived and designed the experiments, authored and reviewed drafts of the paper, and approved the final draft.

## **Human Ethics**

The following information was supplied relating to ethical approvals (i.e., approving body and any reference numbers):

The study was approved by the Ethics Review Committee of the China Medical University Hospital (CMUH106-REC1-004).

## **Data Availability**

The following information was supplied regarding data availability:

The raw measurements are available in the Supplemental Files.
