ABSTRACT

Background. Brown adipose tissue (BAT) dissipates caloric energy as heat and plays a role in glucose and lipid metabolism. Therefore, augmentation and activation of BAT are the focus of new treatment strategies against obesity, a primary risk factor of metabolic syndrome. The vitamin D system plays a crucial role in mineral homeostasis, bone metabolism, and cell proliferation and differentiation. In this study, we investigated the effects of vitamin D₃ [1,25(OH)₂D₃] on brown adipocyte differentiation.

Methods. The mouse fibroblast-like cell line C3H10T1/2 was differentiated into brown adipocytes in the presence of 1,25(OH)₂D₃. The effect of 1,25(OH)₂D₃ on brown adipocyte differentiation was assessed by measuring lipid accumulation, the expression of related genes, and cytotoxicity. The viability of C3H10T1/2 cells was measured using the Cell Counting Kit-8 assay. Gene expression was investigated using quantitative reverse transcription-polymerase chain reaction. Protein expression was estimated using western blotting.

Results. 1,25(OH)₂D₃ inhibited adipocyte differentiation and exerted a cytotoxic effect at 1 nM. However, in the physiological concentration range (50–250 pM), 1,25(OH)₂D₃ promoted uncoupling protein 1 (UCP1) expression in C3H10T1/2 cells. This effect was not observed when 1,25(OH)₂D₃ was added 48 h after the initiation of differentiation, suggesting that the vitamin D system acts in the early phase of the differentiation program. We showed that 1,25(OH)₂D₃ increased the expression of two key regulators of brown adipogenesis, PR domain containing 16 (*Prdm16*) and peroxisome proliferator-activated receptor γ coactivator-1 α (*Pgc1 α*). Furthermore, 1,25(OH)₂D₃ increased *Ucp1* expression in 3T3-L1 beige adipogenesis in a dose-dependent manner.

Conclusion. These data indicate the potential of vitamin D and its analogs as therapeutics for the treatment of obesity and related metabolic diseases.

INTRODUCTION

Obesity is a major risk factor of metabolic syndrome. The increasing prevalence of obesity has become a worldwide concern, and effective treatments for obesity-related diseases are of growing importance. The fundamental cause of obesity is an energy imbalance between

calorie intake and calorie use, and adipose tissue plays an essential role in this process. In general, two types of adipose tissue, white (WAT) and brown adipose tissue (BAT), exist in mammals. WAT stores excess energy as triglycerides, whereas BAT dissipates energy as heat.

BAT specializes in thermogenesis and plays a crucial role in cold adaptation in small rodents by regulating nonshivering thermogenesis. Studies using mouse models have also shown that BAT has a regulatory role in glucose and lipid metabolism ([Stanford et al., 2013](#); [Bartelt et al., 2011](#)). In humans, BAT was initially thought to exist at physiologically significant levels in newborns and to become essentially absent in adults. However, recent studies using positron emission tomography-computed tomography have shown that a physiologically significant amount of BAT exists in adults, and its presence is inversely related to body mass index and levels of visceral fat ([Cypess et al., 2009](#); [Saito et al., 2009](#); [Virtanen et al., 2009](#)). Moreover, BAT activation increases whole-body glucose disposal and insulin sensitivity in humans ([Chondronikola et al., 2014](#); [Orava et al., 2013](#)). BAT also plays a significant role in human whole-body lipid metabolism ([Chondronikola et al., 2016](#)). Recent studies have demonstrated that the presence of BAT correlates with low odds of type 2 diabetes, dyslipidemia, coronary artery disease, cerebrovascular disease, congestive heart failure, and hypertension ([Becher et al., 2021](#)). Chronic cold stimulation or capsinoid intake can lead to the recruitment of BAT even in individuals with low or no detectable BAT activity ([Yoneshiro et al., 2013](#)). Consequently, BAT is emerging as a promising target for the treatment of obesity and related metabolic diseases ([Cheng et al., 2021](#); [Singh et al., 2021](#)).

Vitamin D is well known for its role in the regulation of calcium and phosphate homeostasis. It also regulates proliferation, differentiation, and apoptosis in several cell lines ([Nagpal, Na & Rathnachalam, 2005](#); [Fleet et al., 2012](#)) and is associated with several metabolic processes in the cardiovascular ([Chen et al., 2011](#)) and immune ([Liu et al., 2006](#); [Priehl et al., 2013](#)) systems. Accumulating evidence indicates that vitamin D deficiency is associated with metabolic diseases ([Park, Pichiah & Cha, 2018](#); [Theik et al., 2021](#)).

Several studies have examined the relationship between adipocyte differentiation and vitamin D ([Vu et al., 1996](#); [Kelly & Gimble, 1998](#); [Blumberg et al., 2006](#); [Kong & Li, 2006](#); [Nimitphong et al., 2012](#); [Basoli et al., 2017](#); [Shi et al., 2002](#); [Huang et al., 2002](#); [Duque, Macoritto & Kremer, 2004](#); [Zhuang, Lin & Yang, 2007](#); [Cianferotti & Demay, 2007](#); [Sun & Zemel, 2008](#); [Sakuma et al., 2012](#); [Ricciardi et al., 2015](#); [Chang & Kim, 2016](#)). In most studies, 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃), the most biologically active vitamin D₃ metabolite, has been reported to have an inhibitory effect on adipogenesis. However, certain studies have reported a promoting effect of 1,25(OH)₂D₃ on adipogenesis. These discrepancies have been attributed to differences in the cell types and concentrations of 1,25(OH)₂D₃ used in these studies. Previously, 1,25(OH)₂D₃ was reported to have an inhibitory effect on brown adipocyte differentiation ([Ricciardi et al., 2015](#)). However, the concentration of 1,25(OH)₂D₃ used in that study was far higher than that typically observed in physiological settings. Consequently, the effects of physiological concentrations of 1,25(OH)₂D₃ on brown adipocyte differentiation remain ambiguous.

Therefore, we aimed to demonstrate that $1,25(\text{OH})_2\text{D}_3$ stimulates the brown adipocyte differentiation program at physiologically relevant concentrations. Our findings suggest that vitamin D may have therapeutic utility in the treatment of obesity and related metabolic diseases.

MATERIALS & METHODS

Cell culture and induction of adipogenesis

C3H10T1/2-clone 8 cells (#IF050415) were obtained from the Health Science Research Resources Bank (Osaka, Japan). Cells were grown at 37°C in a 5% CO_2 humidified atmosphere in Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal bovine serum (FBS). On reaching confluency, cells were induced to differentiate into brown adipocytes by supplementing the culture medium with $10\ \mu\text{g}/\text{mL}$ insulin (Nacalai Tesque, Kyoto, Japan), $1\ \mu\text{M}$ dexamethasone (DEX; Sigma-Aldrich, St. Louis, MO, USA), $0.5\ \text{mM}$ 3-isobutyl-1-methylxanthine (IBMX; Sigma-Aldrich), $125\ \mu\text{M}$ indomethacin (Cayman Chemical, Ann Arbor, MI, USA), and $3\ \text{nM}$ 3,3,5-triiodo-L-thyronine (T3; Sigma-Aldrich). Two days after stimulation, the medium was replaced with DMEM supplemented with 10% FBS, $10\ \mu\text{g}/\text{mL}$ insulin, and $3\ \text{nM}$ T3 as previously described (Kusudo *et al.*, 2019). Thereafter, the medium was changed every two days for a period of seven to eight days. Cells were treated with $1,25(\text{OH})_2\text{D}_3$ (Sigma-Aldrich) at the indicated doses depending on the experiment. 3T3-L1 cells (Japanese Collection of Research Bioresources Cell Bank, Tokyo, Japan) were stimulated for differentiation using DMEM, containing 10% FBS, $10\ \mu\text{g}/\text{ml}$ insulin, $1\ \mu\text{M}$ DEX, and $0.5\ \text{mM}$ IBMX, for two days, followed by DMEM supplemented with 10% FBS and $10\ \mu\text{g}/\text{ml}$ insulin. The medium was changed every two days for eight days. $1,25(\text{OH})_2\text{D}_3$ or ethanol was added to the media during the experiment. For beige adipocyte differentiation, 3T3-L1 cells were differentiated with DMEM, supplemented with 10% FBS, $10\ \mu\text{g}/\text{ml}$ insulin, $1\ \mu\text{M}$ DEX, and $0.5\ \text{mM}$ IBMX, $10\ \mu\text{M}$ rosiglitazone (Sigma-Aldrich), and $3\ \text{nM}$ T3, for 48 h (Asano *et al.*, 2014). Subsequently, the medium was replaced with DMEM containing 10% FBS, $10\ \mu\text{g}/\text{mL}$ insulin, $10\ \mu\text{M}$ rosiglitazone and $3\ \text{nM}$ T3 every two days for eight days. The cells were stimulated with $10\ \mu\text{M}$ isoproterenol for 4 h before harvesting.

Vitamin D receptor (VDR) silencing in C3H10T1/2 cells

The VDR and negative control Stealth small interfering RNAs (siRNAs) (#MSS238646 and #12935200, respectively) were obtained from Thermo Fisher Scientific (Waltham, MA, USA). siRNAs were transfected into cells using Lipofectamine RNAiMAX reagent (Thermo Fisher Scientific) according to the manufacturer's protocol. The following day, the medium was replaced with DMEM supplemented with 10% FBS. Three days after transfection, the medium was replaced with a differentiation medium for differentiation into brown adipocytes. In addition, to enhance UCP1 expression, C3H10T1/2 cells were stimulated with $1\ \mu\text{M}$ all-trans retinoic acid (Sigma-Aldrich) for the last 24 h of differentiation.

Quantitative reverse transcription-polymerase chain reaction (qRT-PCR)

Total RNA was extracted using TRI Reagent (Molecular Research Center Inc., Cincinnati, OH, USA), according to the manufacturer's protocol. To quantify mRNA expression levels, qRT-PCR analysis was performed using a StepOne real-time PCR system (Applied Biosystems, Foster City, CA, USA) and PowerUp SYBR Green Master Mix (Thermo Fisher Scientific), as described previously ([Kusudo et al., 2019](#)). All gene expression data were normalized to the 36B4 expression levels. The respective sense and antisense oligonucleotide primers for the target genes were as follows: *Cebpa*, 5'-CAAGAACAGCAACGAGTACCG-3' and 5'-GTCACTGGTCAACTCCAGCAC-3'; *Cebpb*, 5'-ACGACTTCCTCTCCGACCTCT-3' and 5'-CGAGGCTCACGTAACCGTAGT-3'; *Cebpd*, 5'-CGACTTCAGCGCCTACATTGA-3' and 5'-CTAGCGACAGACCCACAC-3'; *Plin*, 5'-CTGTGTGCAATGCCTATGAGA-3' and 5'-CTGGAGGGTATTGAAGAGCCG-3'; *Vdr*, 5'-GAATGTGCCTCGGATCTGTGG-3' and 5'-ATGCGGCAATCTCCATTGAAG-3'; *Cox7a1*, 5'-AGAAAACCGTGTGGCAGAGA-3' and 5'-CAGCGTCATGGTCAGTCTGT-3'; *Cox8b*, 5'-GCGAAGTTCACAGTGGTTCC-3' and 5'-GAACCATGAAGCCAACGACT-3'; *MT-CO1*, 5'-CAAGAACAGCAACGAGTACCG-3' and 5'-GTCACTGGTCAACTCCAGCAC-3'; and *Ndfv1*, 5'-ACGACTTCCTCTCCGACCTCT-3' and 5'-CGAGGCTCACGTAACCGTAGT-3'. All other oligonucleotide primer sets used in this study have been described previously ([Kusudo et al., 2019](#); [Hashimoto et al., 2019](#)).

Western blot analysis

Western blotting was performed as previously described ([Mukai et al., 2017](#)). Briefly, C3H10T1/2 cells were lysed with radioimmunoprecipitation assay buffer, and protein concentrations were determined using the Pierce BCA Protein Assay Kit (Thermo Fisher Scientific). Samples containing equal amounts of protein were separated by sodium dodecyl sulfate–polyacrylamide gel electrophoresis and subsequently transferred onto polyvinylidene difluoride membranes (Millipore, Bedford, MA, USA). These membranes were incubated overnight at 4°C with primary antibodies against FABP4 (12802-1-AP; Proteintech, Rosemont, IL, USA), VDR (#12550; Cell Signaling Technology, Danvers, MA, USA), UCP1 (sc-518171; Santa Cruz Biotechnology, Inc., Dallas, TX, USA), CIDEA (13170-1-AP; Proteintech), PPAR γ (#2435; Cell Signaling Technology), PPAR α (15540-1-AP; Proteintech), FGF21 (ab171941; Abcam, Cambridge, UK) and α/β -tubulin (#2148, Cell Signaling Technology). The membranes were then washed and incubated with horseradish peroxidase–labeled secondary antibodies for 1 h at room temperature. Immunoreactivity was determined using Immobilon-P (Millipore) or Chemi-Lumi One L (Nacalai Tesque), and chemiluminescence was visualized using Amasham Imager 680 (GE Healthcare, Chicago, IL, USA).

Oil Red O staining

Cells were washed with phosphate-buffered saline, fixed with 4% paraformaldehyde, and stained with Oil Red O (Merck Millipore, Billerica, MA, USA). Images were captured using a BZX-700 microscope (Keyence, Osaka, Japan). To quantify lipid levels, the stain was

dissolved in isopropyl alcohol, and its absorbance was measured at 490 nm using an iMark microplate absorbance reader (Bio-Rad Laboratories, Hercules, CA, USA).

Cell viability

The viability of pre-differentiated and differentiated C3H10T1/2 cells was measured using the Cell Counting Kit-8 (Dojindo Molecular Technologies, Inc., Kumamoto, Japan) according to the manufacturer's instructions. In addition, the absorbance at 570 nm was measured using an iMark microplate absorbance reader (Bio-Rad Laboratories).

Reporter assay

Reporter assays were performed as previously described ([Kusudo et al., 2019](#)). C3H10T1/2 cells were transfected with pGL4.21-UCP1 and pRL-TK. In addition, 24 h later, cells were stimulated with 100 pM 1,25(OH)₂D₃ for 24 h. Cells were lysed, and the luciferase activity was measured using the Dual-Luciferase System (Promega, Madison, WI, USA).

Quantification of relative mitochondrial copy number

C3H10T1/2 cells were differentiated for eight days. Total DNA was isolated using the NucleoSpin DNA RapidLyse (Takara Bio, Kyoto, Japan) according to the manufacturer's instructions. To calculate relative mitochondrial DNA copy number, the expression of mitochondrially encoded cytochrome C oxidase I (*MT-CO1*) and NADH dehydrogenase [ubiquinone] flavoprotein 1 (*Ndifu1*) genes was quantified using qRT-PCR ([Amthor et al., 2007](#)).

Statistical analysis

Data are expressed as mean \pm standard error of the mean. The number of samples was three to six for RT-qPCR and four for Oil Red O staining, cell viability assay, and the reporter assay. The significance of differences between two groups was assessed using Student's *t*-test. The significance of differences between multiple groups was assessed using a one-way analysis of variance followed by Dunnett's *post hoc* test. Statistical significance was set at $p < 0.05$.

RESULTS

VDR is required for brown adipogenesis of C3H10T1/2 cells

To investigate the relationship between vitamin D signaling and brown adipocyte differentiation, we first examined the expression of VDR in C3H10T1/2 cells, an established model of brown adipogenesis ([Brunmeir et al., 2016](#)) ([Fig. 1A](#)). After differentiation, the mRNA expression of the adipogenic markers fatty acid-binding protein 4 (*Fabp4*) and peroxisome proliferator-activated receptor γ (*Ppar γ*) and that of the brown adipogenesis-related genes uncoupling protein 1 (*Ucp1*), cell death-inducing DFFA-like effector A (*Cidea*), *Ppar α* , and fibroblast growth factor 21 (*Fgf21*) significantly increased ($p < 0.001$). The expression of these genes was confirmed at the protein level ([Fig. 1B](#)). The mRNA expression of *Vdr* decreased transiently after stimulation (day 2) but recovered on day 4 and thereafter. However, at the protein level, VDR expression decreased after the differentiation ([Fig. 1B](#)).

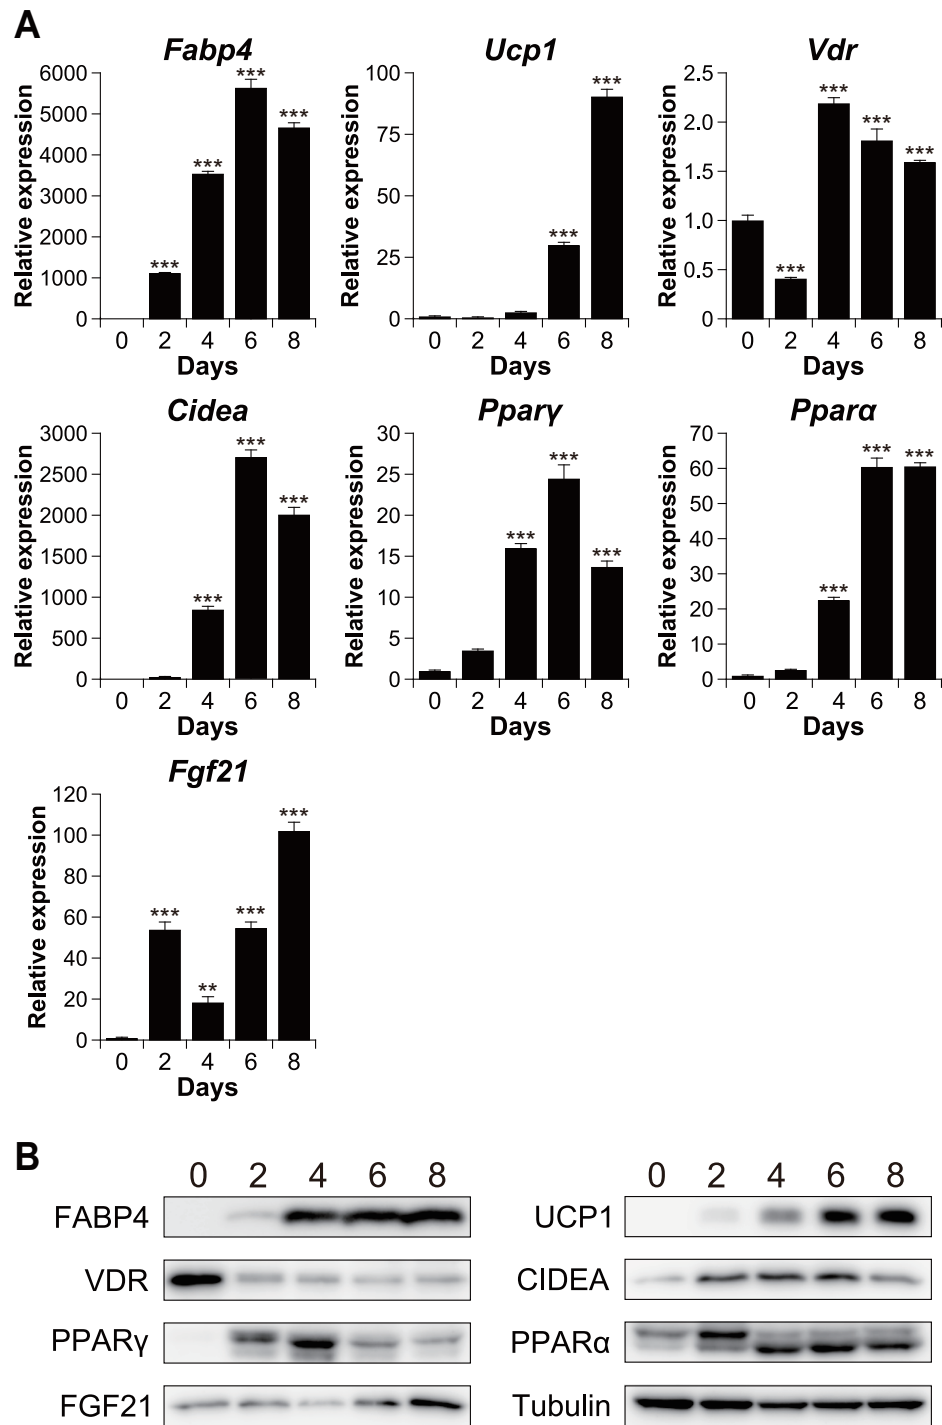

Figure 1 Time course analysis of mRNA and protein expression during brown adipocyte differentiation of C3H10T1/2 cells. (A) mRNA expression of *Fabp4*, *Ucp1*, *Vdr*, *Cidea*, *Ppar γ* , *Ppara*, and *Fgf21*, as measured using quantitative reverse transcription-polymerase chain reaction ($n = 4$). Representative images with three samples of each siRNA are shown. Data are shown as mean \pm standard error of the mean. *** $p < 0.001$.

Full-size DOI: [10.7717/peerj.14785/fig-2](https://doi.org/10.7717/peerj.14785/fig-2)

To examine the contribution of VDR to brown adipogenesis in C3H10T1/2 cells, we performed knockdown experiments using siRNA for *Vdr* in C3H10T1/2 cells (Fig. 2A). VDR knockdown significantly inhibited the differentiation of C3H10T1/2 cells (Fig. 2B). In addition, the expression of *Ucp1* and adipogenic markers *Fabp4* and perilipin (*Plin*) were significantly reduced in VDR knockdown cells compared to the control cells (all $p < 0.001$, Fig. 2C). Decreased UCP1 expression was also confirmed at the protein level (Fig. 2D). These results suggest that VDR plays a vital role in brown adipocyte differentiation.

Effect of 1,25(OH)₂D₃ concentration on brown adipocyte differentiation

To explore the role of vitamin D signaling in brown adipocyte differentiation, we investigated the effects of 1,25(OH)₂D₃ on brown adipocyte differentiation in C3H10T1/2 cells. As shown in Figs. 3A and 3B, high concentrations of 1,25(OH)₂D₃ suppressed lipid accumulation in the C3H10T1/2 cells cultured in adipogenic medium. In addition, consistent with Oil Red O staining, the expression of *Plin* (adipogenic and lipid droplet accumulation marker) decreased depending on the concentration of 1,25(OH)₂D₃ (Fig. 3C). Figure 3D shows the cytotoxic effect of 1,25(OH)₂D₃ on pre-differentiated or differentiated C3H10T1/2 cells. While 100 pM 1,25(OH)₂D₃ did not exert cytotoxic effects on either stage of C3H10T1/2 cells, 1,000 pM 1,25(OH)₂D₃ showed significant cytotoxic effects on both cell types ($p < 0.001$).

Furthermore, we examined *Ucp1* mRNA expression in 1,25(OH)₂D₃-treated cells. Similar to the lipid accumulation results, at a high concentration of 1,25(OH)₂D₃, *Ucp1*

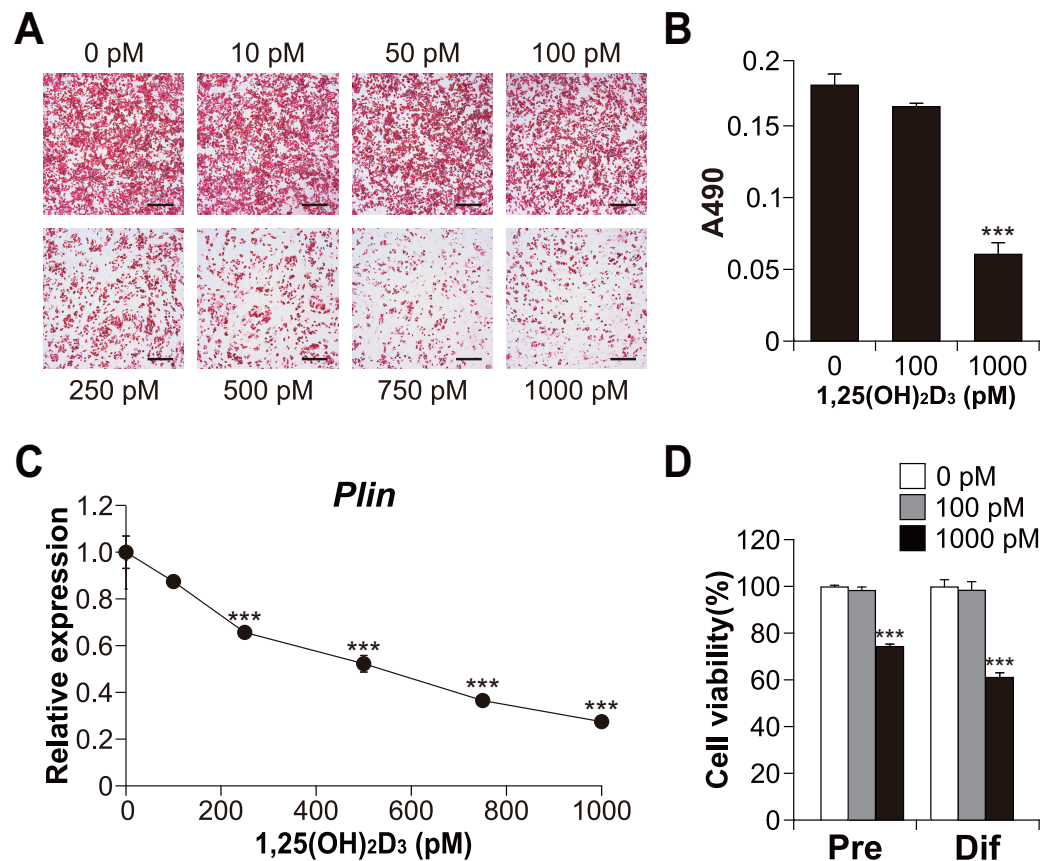

Figure 3 Effects of 1,25(OH)₂D₃ on the differentiation and viability of C3H10T1/2 cells. (C) Dose-dependent effects of 1,25(OH)₂D₃ on *Plin* mRNA expression ($n = 3$). (D) Effect of 1,25(OH)₂D₃ on C3H10T1/2 viability. Pre-differentiated (Pre) or differentiated (Dif) C3H10T1/2 cells were treated with 100 pM or 1000 pM 1,25(OH)₂D₃ for 24 h ($n = 4$). Data are shown as mean \pm standard error of the mean. *** $p < 0.001$ versus control (0 pM).

Full-size [DOI: 10.7717/peerj.14785/fig-3](https://doi.org/10.7717/peerj.14785/fig-3)

expression decreased in a dose-dependent manner (Fig. 4A). However, *Ucp1* mRNA expression increased at low concentrations of 1,25(OH)₂D₃ (50–250 pM). UCP1 expression was confirmed at the protein level (Fig. 4B). Analysis of the effects of high (1,000 pM) and low (100 pM) concentrations of 1,25(OH)₂D₃ on the expression of different adipocyte differentiation markers revealed that the PR domain containing 16 (*Prdm16*), a master regulator of BAT differentiation, was significantly elevated in cells treated with 100 pM 1,25(OH)₂D₃ when compared with control cells ($p = 0.030$, Fig. 4C). Notably, 100 pM 1,25(OH)₂D₃ did not affect the expression of the white adipocyte-specific markers resistin (*Retn*) and angiotensinogen (*Agt*) or the adipogenic genes *Fabp4* and *Plin* when compared with the control cells. Except for *Prdm16*, the expression of all these genes was suppressed following treatment with 1,000 pM 1,25(OH)₂D₃ ($p < 0.001$), suggesting that a high concentration of 1,25(OH)₂D₃ inhibits the differentiation of C3H10T1/2 cells into brown and white adipocytes. At 100 pM, 1,25(OH)₂D₃ did not increase mitochondrial

copy number (Fig. 4D) but significantly increased the mRNA expression of cytochrome c oxidase polypeptide (*Cox7a1* ($p = 0.05$) and *Cox8b* ($p < 0.001$), which are brown fat-selective mitochondrial genes (Fig. 4E). The blood concentration of $1,25(\text{OH})_2\text{D}_3$ is typically within 2–350 pM (Ryan et al., 2013), suggesting that a low concentration of $1,25(\text{OH})_2\text{D}_3$ stimulates the brown adipogenic program at physiological concentrations.

$1,25(\text{OH})_2\text{D}_3$ affects the differentiation phase of brown adipogenesis

To determine whether $1,25(\text{OH})_2\text{D}_3$ affects the early or late phase of brown adipogenesis, C3H10T1/2 cells were treated with $1,25(\text{OH})_2\text{D}_3$ specifically during the differentiation phase (first 48 h) and cultured without $1,25(\text{OH})_2\text{D}_3$ (days 2 to 7). As shown in Fig. 5A, treatment with 100 pM $1,25(\text{OH})_2\text{D}_3$ for the first two days increased *Ucp1* and *Fabp4* mRNA expression in C3H10T1/2 cells compared to that in the control cells ($p = 0.019$ and $p = 0.049$, respectively). *Plin* expression, however, remained unchanged. We then investigated the effect of $1,25(\text{OH})_2\text{D}_3$ on the maturation phase of brown adipogenesis (days 2 to 7). To achieve this, C3H10T1/2 cells were initially differentiated in the absence of $1,25(\text{OH})_2\text{D}_3$ and then treated with 100 pM $1,25(\text{OH})_2\text{D}_3$ from days 2 to 7. The addition of $1,25(\text{OH})_2\text{D}_3$ did not affect the expression of *Ucp1*, *Fabp4*, or *Plin*. UCP1 protein expression under both conditions showed the same tendency as the mRNA expression (Fig. 5B). Therefore, a physiological concentration of $1,25(\text{OH})_2\text{D}_3$ enhanced brown adipocyte differentiation of C3H10T1/2 cells by acting during the early stages of brown adipogenesis. To further understand the molecular mechanism by which $1,25(\text{OH})_2\text{D}_3$ stimulates the brown adipocyte differentional program, we examined the expression of transcription factors 48 h after induction of differentiation. As shown in Fig. 5C, $1,25(\text{OH})_2\text{D}_3$ treatment significantly increased the mRNA expression of *Prdm16* and peroxisome proliferator-activated receptor γ coactivator-1 α (*Pgc1 α*) and slightly decreased the expression of CCAAT-enhancer-binding protein α (*Cebpa*) ($p < 0.001$, $p = 0.003$, and $p < 0.001$, respectively). *Ppara α* , *Ppar γ* , and *Cidea* were unaffected by $1,25(\text{OH})_2\text{D}_3$ treatment. Studies have reported that at an early stage of differentiation, the CEBP family and PPAR γ play an essential role in brown and white adipogenesis (Wu, Bucher & Farmer, 1996; Yubero et al., 1994; Manchado et al., 1994). Therefore, we further investigated the expression levels of *Ppar γ* , *Cebpa*, *Cebpb*, and *Cebpd* 12 h after the initiation of differentiation. However, the addition of $1,25(\text{OH})_2\text{D}_3$ did not alter the mRNA expression of these genes (Fig. 5D). Malloy & Feldman (2013) reported that VDR directly modulates UCP1 expression. The effect of $1,25(\text{OH})_2\text{D}_3$ on *Ucp1* promoter activity was examined. As shown in Fig. 5E, *Ucp1* promoter activity was not affected by adding $1,25(\text{OH})_2\text{D}_3$.

$1,25(\text{OH})_2\text{D}_3$ inhibits white adipocyte differentiation in a dose-dependent manner but enhances *Ucp1* expression in 3T3-L1 beige adipogenesis

We also examined whether the effect of $1,25(\text{OH})_2\text{D}_3$ on differentiation in the physiological range is specific to brown adipocyte differentiation. To investigate the effect of $1,25(\text{OH})_2\text{D}_3$ on white adipocyte differentiation, 3T3-L1 cells, a widely used white adipocyte differentiation model, were differentiated with $1,25(\text{OH})_2\text{D}_3$. As shown in Fig. 6A, treatment with 1,000 pM $1,25(\text{OH})_2\text{D}_3$ inhibited the differentiation of 3T3-L1

C3H10T1/2 cells were differentiated in the absence or presence of 100 pM 1,25(OH)₂D₃. mRNA levels of *Prdm16*, *Pgc1α*, *Pparα*, *Pparγ*, *Cidea*, and *Cebpa* were measured 48 h after the initiation of differentiation ($n = 4$). (D) Expression of adipogenesis-related transcription factors during the early stages of differentiation. C3H10T1/2 cells were differentiated in the absence or presence of 100 pM 1,25(OH)₂D₃ 12 h after differentiation initiation, and the mRNA levels of *Pparγ*, *Cebpa*, *Cebpb*, and *Cebpd* were measured using quantitative reverse transcription-polymerase chain reaction ($n = 3$). (E) Effect of 1,25(OH)₂D₃ on the stimulation of *Ucp1* promoter activity ($n = 4$). Data are shown as mean ± standard error of the mean. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ versus control (0 pM).

cells. At 100 pM, there was no apparent morphological difference in 3T3-L1 cells compared to that in the control, but the *Plin* mRNA level was slightly decreased ($p = 0.025$, Fig. 6B). In addition, the expression of *Plin* and adiponectin (*Adipoq*) was significantly reduced at 1,000 pM 1,25(OH)₂D₃ ($p < 0.001$ and $p = 0.011$, respectively). Thus, 1,25(OH)₂D₃ inhibits white adipocyte differentiation in a dose-dependent manner. To investigate the inhibitory effect of 1,25(OH)₂D₃ on white adipogenesis of 3T3-L1, we measured the expression of *Pparγ*, *Cebpa*, and *Cebpb* after 48 h of initiation of differentiation. At 1,000 pM, 1,25(OH)₂D₃ significantly downregulated these genes ($p < 0.001$, $p < 0.001$, and $p = 0.010$, respectively, Fig. 6C), which suggested that the inhibitory effect of 1,25(OH)₂D₃ on 3T3-L1 differentiation is exerted through suppression of regulator gene expression. 3T3-L1 cells were reported to differentiate into beige adipocytes with long-term treatment with rosiglitazone, T3, and IBMX (Asano et al., 2014). Therefore, we verified the effect of 1,25(OH)₂D₃ on beige adipogenesis of 3T3-L1. As shown in Fig. 6D, 1,25(OH)₂D₃ significantly increased *Ucp1* mRNA expression in a dose-dependent manner at 100 pM ($p = 0.011$) or higher ($p < 0.001$).

DISCUSSION

In this study, we investigated the effects of 1,25(OH)₂D₃ on brown adipocyte differentiation of C3H10T1/2 cells. We found that 1,25(OH)₂D₃ has a biphasic effect on this process, with physiological concentrations enhancing differentiation and high concentrations inhibiting differentiation.

In a previous study, Ricciardi et al. (2015) reported that 1,25(OH)₂D₃ inhibited brown adipocyte differentiation and mitochondrial respiration in a dose-dependent manner (Ricciardi et al., 2015). The discrepancy between their data and the present study is probably the differences in the concentration of 1,25(OH)₂D₃ and cell types used in both studies. The 1,25(OH)₂D₃ concentration used in their study was greater than 1 nM, which is very high compared to the physiological concentration. Although the working concentrations in our experiment differed from those in their study, 1,25(OH)₂D₃ also inhibited brown adipogenesis of C3H10T1/2 cells in the high concentration range. However, at a physiologically relevant concentration of 100 pM (i.e., within the 2–350 pM serum concentration range), 1,25(OH)₂D₃ positively stimulated brown adipogenesis.

Several studies have reported that 1,25(OH)₂D₃ exerts an inhibitory effect on white adipocyte differentiation (Kelly & Gimble, 1998; Blumberg et al., 2006; Kong &

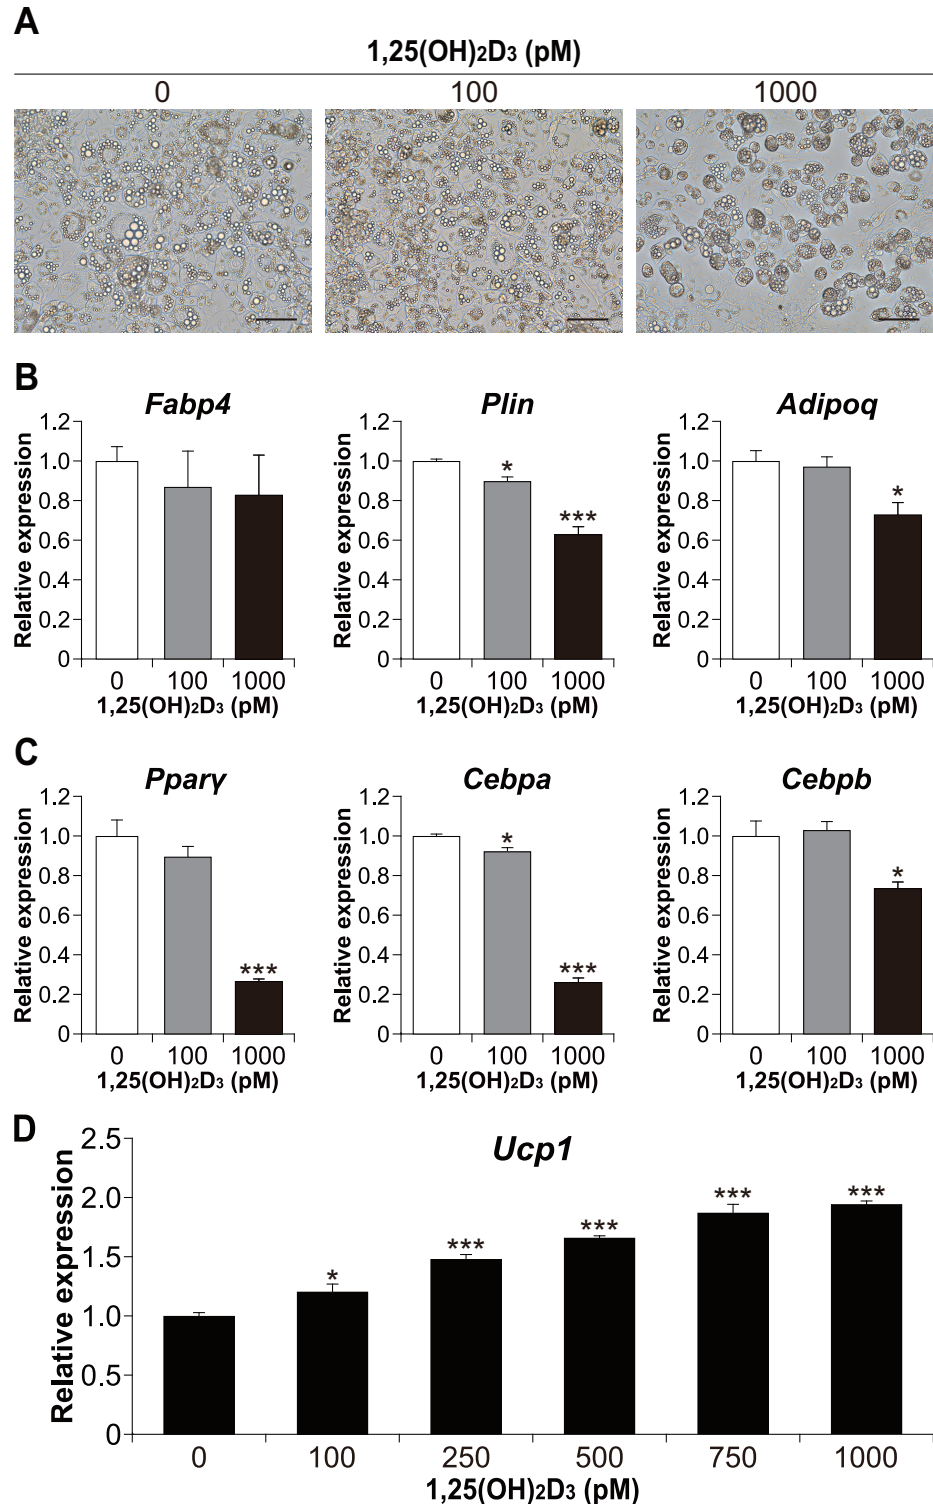

Figure 6 1,25(OH)₂D₃ inhibits white adipogenesis in 3T3-L1 cells but promotes beige adipocyte differentiation in 3T3-L1 cells. 3T3-L1 cells were differentiated with 0 pM (EtOH), 100 pM, or 1000 pM 1,25(OH)₂D₃. on day eight. Scale bars, 100 μm . (B) mRNA levels of *Fabp4*, *Plin*, and *Adipoq* on day six ($n = 4$). (C) Expression of adipogenesis-related transcription factors. 3T3-L1 cells were differentiated in the absence or presence of $1,25(\text{OH})_2\text{D}_3$. mRNA levels of *Ppar γ* , *Cebpa*, and *Cebpb* were measured 48 h after the initiation of differentiation ($n = 4$). (D) 3T3-L1 cells differentiated for eight days under browning conditions supplemented with various concentration of $1,25(\text{OH})_2\text{D}_3$. mRNA expression of *Ucp1* was measured by real-time reverse transcription polymerase chain reaction ($n = 4$). Data are shown as mean \pm standard error of the mean. * $p < 0.05$, *** $p < 0.001$ versus 0 pM.

Li, 2006; Basoli et al., 2017; Zhuang, Lin & Yang, 2007; Sakuma et al., 2012). Similarly, $1,25(\text{OH})_2\text{D}_3$ suppressed 3T3-L1 differentiation in our results at both 100 pM and 1000 pM concentrations. This suggests that $1,25(\text{OH})_2\text{D}_3$ exerts a suppressive effect on white adipocyte differentiation and has distinct effects on brown and white adipogenesis. Furthermore, *Kong & Li (2006)* reported that $1,25(\text{OH})_2\text{D}_3$ blocks the adipogenic program in 3T3-L1 cells by suppressing the expression of *Cebpa* and *Ppar γ* , the master regulators of adipogenesis. This result was confirmed in our study (Fig. 6C). In our experiments using C3H10T1/2 cells, $1,25(\text{OH})_2\text{D}_3$ treatment slightly decreased *Cebpa* mRNA expression but did not stimulate the expression of *Ppar γ* . However, we observed a significant increase in the expression of *Prdm16* and *Pgc1 α* in cells treated with 100 pM $1,25(\text{OH})_2\text{D}_3$, which suggested that $1,25(\text{OH})_2\text{D}_3$ stimulates brown adipogenesis via *Prdm16* and *Pgc1 α* upregulation. Further studies are required to clarify the precise mechanism by which $1,25(\text{OH})_2\text{D}_3$ increases *Prdm16* and *Pgc1 α* expression.

The role of the vitamin D system in energy metabolism has been explored in VDR knockout mice (*Wong et al., 2009; Narvaez et al., 2009*). These mice demonstrated lower body fat mass, higher energy expenditure, and increased UCP1 expression in WAT. These results suggest a suppressive role for vitamin D signaling in BAT generation and, therefore, seem to contradict our findings. However, VDR knockout mice also show a lean and alopecia-like phenotype (*Sakai & Demay, 2000; Li et al., 1997*). The thermoneutral temperature for mice is approximately 30°C ; therefore, normal housing conditions ($18\text{--}23^\circ\text{C}$) impose chronic thermal stress on these animals (*Feldmann et al., 2009; Cannon & Nedergaard, 2011*). The increase in body surface area and hair loss may make VDR knockout mice feel colder than the control mice. The sympathetic nervous system, the most important stimulus for adipose tissue browning, may demonstrate elevated activity in VDR knockout mice compared with that in the control mice. Consequently, increased energy expenditure and UCP1 expression in WAT may represent compensatory effects associated with a cold environment rather than a direct effect of the vitamin D system. Experiments conducted under thermoneutral conditions are needed to clarify the role of the vitamin D system in brown fat generation and energy expenditure. High energy expenditure, as seen in VDR knockout mice, is contrary to the findings of the majority of human studies that show an inverse correlation between adiposity/obesity and vitamin D status (*Bell et al., 1985; Snijder et al., 2005*). Our results support the findings of those human epidemiological and clinical studies.

CONCLUSIONS

In the brown adipogenesis of C3H10T1/2 cells, a high concentration of $1,25(\text{OH})_2\text{D}_3$ inhibits differentiation; however, the physiological concentration of $1,25(\text{OH})_2\text{D}_3$ upregulates certain brown adipose markers such as *Ucp1*, *Prdm16*, and *Pgc1 α* . In addition, *Ucp1* expression was induced by $1,25(\text{OH})_2\text{D}_3$ in the beige adipogenesis of 3T3-L1 cells. Further studies should be performed to clarify the underlying molecular mechanism and demonstrate the effect *in vivo*. Nevertheless, our findings suggest that supplementation of vitamin D and its analogs may represent an effective therapeutic strategy for the treatment of obesity and related metabolic diseases through the promotion and inhibition of brown and white adipocyte differentiation, respectively.

ACKNOWLEDGEMENTS

The authors are grateful to Dr. Nobuko Iritani and Dr. Hitomi Fukuda for their support throughout this study. We would like to thank Editage for English language editing.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by Grant-in-Aid for Scientific Research (KAKENHI) from the Japan Society for the Promotion of Science (Grant Number 18K05511 to Tatsuya Kusudo). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
Japan Society for the Promotion of Science: 18K05511.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Takako Mukai performed the experiments, analyzed the data, authored or reviewed drafts of the article, and approved the final draft.
- Tatsuya Kusudo conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.

Data Availability

The following information was supplied regarding data availability:
The raw measurements are available in the [Supplemental Files](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.14785#supplemental-information>.
