A new, partially preserved skull of chigutisaurid amphibian (*Temnospondyli*) has been reported for the first time from the Late Triassic Tiki Formation of India. The specimen belongs to the genus *Compsocerops* prevalent in the Late Triassic Maleri Formation occurring 700 km south. However, the chigutisaurid specimen recovered from the Tiki Formation is a new species when compared to that of the Maleri Formation. Biostratigraphically, it proves that the Tiki Formation, is not only coeval with the Lower Maleri Formation but also a part of Upper Maleri too. Chigutisaurids are now known to occur in the Early and Late Triassic of Australia, Late Triassic in India, Argentina and Brazil, in Jurassic of South Africa and Australia and Cretaceous of Australia. In India the first appearance of chigutisaurids marks the Carnian – Norian Boundary. This work also attempts to correlate, again for the first time, the advent of chigutisaurids and the occurrence of Carnian Pluvial Events in Late Triassic Maleri and Tiki Formation of Central India.

12 Abstract

13 A new, partially preserved skull of chigutisaurid amphibian (Temnospondyli) has been reported

14 for the first time from the Late Triassic Tiki Formation of India. The specimen belongs to the

15 genus *Compsocerops* prevalent in the Late Triassic Maleri Formation occurring 700 km south.

16 However, the chigutisaurid specimen recovered from the Tiki Formation is a new species when

17 compared to that of the Maleri Formation. Biostratigraphically, it proves that the Tiki Formation

18 is coeval with the Lower Maleri Formation and a part of Upper Maleri. Chigutisaurids are now

19 known to occur in Australia's Early and Late Triassic, the Late Triassic in India, Argentina, and

20 Brazil, the Jurassic of South Africa and Australia, and the Cretaceous of Australia. In India, the

21 first appearance of chigutisaurids marks the Carnian – middle Carnian / Norian Boundary. This

22 work also attempts to correlate, again for the first time, the advent of chigutisaurids and the

23 occurrence of Carnian Pluvial Episodes in the Late Triassic Maleri and Tiki Formation of Central

24 India.

25 Introduction

26 Temnospondyls are a very diverse and widespread group of extinct amphibians that thrived from
27 Carboniferous to Cretaceous reaching their peak in the Triassic. Capable of flourishing in both
28 land and water in a variety of ecological niches, the fossils of these extinct amphibians are found
29 in almost all places from Antarctica in the South to Greenland in the North, India being no
30 exception. The temnospondyl fossils in India are found in various Gondwana deposits
31 throughout the country. Chigutisaurids are by far one of the most important temnospondyl
32 amphibians, the majority of which originated in the Upper Carnian to Lower Norian of the Late
33 Triassic Period and continued till the Cretaceous. The family Chigutisauridae is much less
34 diversified than the other temnospondyl families. Falling within the superfamily Brachiopoidea
35 which comprises parabolic, brevirostrine skulled temnospondyls, Chigutisauridae forms a single
36 monophyletic family in the phylogenetic position. The spatial and temporal distribution of the
37 chigutisauridae ([Cabrera 1944](#); [Rusconi 1949](#); [Rusconi 1951](#); [Bonaparte 1975](#); [Warren 1981](#); [Warren &](#)
38 [Hutchinson 1983](#); [Warren & Hutchinson 1983](#); [Sengupta 1995](#); [Marsicano 1999](#); [Warren & Marsicano](#)
39 [2000](#); [Bandyopadhyay & Ray 2020a](#); [Dias-da-Silva et al. 2012](#); [Pledge 2013](#)) is schematically
40 represented in Table -1 along with their general habitat. The earliest origin is in the Early
41 Triassic of Australia with the latest being in the Cretaceous of Australia as well. So far, the
42 origin and diversification of chigutisaurids remain restricted only to the Gondwana countries.

43 The Gondwana Successions of India are exposed in four discrete basins coinciding with some of
44 the major river valleys throughout the Indian Subcontinent ([Robinson 1970](#); [Pascoe 1973](#); [Veevers](#)
45 [& Tewari 1995](#)). Of these, the Late Triassic Maleri and the Tiki Formations of the Pranhita-
46 Godavari Valley Basin and the Son Valley Basin respectively are long known to be coeval
47 ([Robinson 1970](#); [Chatterjee & Roy-Chowdhury 1974](#); [Kutty & Sengupta 1989](#); [Mukherjee & Ray 2014](#)).

48 Both Formations are known for the metoposaurid *Panthesaurus maleriensis* ([Sengupta 2002](#);
49 [Chakravorti & Sengupta 2019](#)) In the Late Triassic Maleri Formation *P. maleriensis* is thought to
50 be restricted within the Carnian and the chigutisaurids appear in the mid-Carnian to early Norian
51 ([Sengupta 1995](#); [Chakravorti & Sengupta 2019](#)). Though a considerable amount of work has been
52 done on the microvertebrates ([Ray et al. 2016a](#); [Bhat 2017](#); [Hussain 2018](#)) rhynchosaurs ([Mukherjee](#)
53 [& Ray 2012](#); [Mukherjee & Ray 2014](#)) and phytosaurs ([Datta et al. 2019](#); [Datta et al. 2021a](#); [Datta et al.](#)
54 [2021b](#)) of the Tiki Formation; no comprehensive work has been done in the last decade on its
55 temnospondyl faunal contents. ([Chakravorti & Sengupta 2019](#)) in their taxonomic revision of the
56 Indian metoposaurids, included the metoposaurids of the Tiki Formation and grouped them into a
57 new genus *Panthesaurus maleriensis* based on morphometric and phylogenetic approaches.
58 However, the biostratigraphic implications of the Tiki Formation based on its temnospondyl
59 contents have not been attempted so far. Taphonomic aspects of *Panthesaurus* have recently
60 been studied by ([Rakshit & Ray 2020](#)). Also, to date, no chigutisaurid remains were reported from
61 the Late Triassic Tiki Formation though the same is widely prevalent in the Late Triassic Maleri
62 Formation ([Sengupta 1995](#)). Therefore, the finding of a chigutisaurid amphibian from the Late
63 Triassic Tiki Formation is very important in the context of correlating the Late Triassic Maleri
64 and Tiki Formation, India, and their position concerning global biostratigraphic correlation. This
65 paper will subsequently highlight a brief geological setting of the Tiki Formation followed by the
66 taxonomic status of chigutisaurids from the Tiki Formation and subsequently its role in
67 demarcating the Carnian Pluvial Episode in India.

68 Geological setting of the Tiki Formation

69 The Tiki Formation named after a small village of Tiki in the district of Shahdol, Madhya
70 Pradesh has been an interest to scientists for decades. Reports on the geology and palaeontology

71 of the Tiki Formation date back to as early as 1877 when ([Hughes 1877](#)) noticed reptilian fossils
72 near this village. ([Cotter 1917](#)) noticed several other such fossils and finally ([Fox 1931](#)) formally
73 designated the area as the “Tiki stage”. ([Aiyengar 1937](#)) first divided the “Tiki stage” into
74 lithostratigraphic units viz. the lower unit being fossiliferous and composed dominantly of red
75 and green mudstones, proportionately lesser number of sandstones and mud-galls while the
76 upper unit is composed of ferruginous sandstones and shales. ([Robinson 1970](#)) in her memoir kept
77 the Tiki Formation to be coeval with the Late Triassic Maleri Formation. However, ([Dutta &](#)
78 [Ghosh 1993](#)) did not recognize the separate entity of the Tiki Formation and placed Tiki rocks in
79 the upper part of the Pali Formation forming the “Pali-Tiki Formation”. ([Roychowdhury et al.](#)
80 [1975](#)) based on the megaflora assemblage noted the age of the Nidhipur beds is Anisian and
81 separated the upper part of the Tiki Formation to be Carnian – Rhaetian in age. ([Maheshwari et al.](#)
82 [1976](#)) separated the Tiki Formation to be a separate entity (including the Nidhipur beds) and
83 based on the mega flora and faunal assemblages suggested the age of the Tiki (including
84 Nidhipur beds) Formation to be ranging from Anisian to Norian with a possible extension to
85 Rhaetian. ([Mukherjee et al. 2012](#)) revised the stratigraphy of the Rewa Basin and put the Tiki
86 Formation with the coeval Carnian Lower Maleri Formation. ([Ray et al. 2016b](#)) the study of
87 vertebrate faunal assemblage of the Tiki formation also suggested Tiki Formation be of Carnian
88 in age but they narrowed the range to Otischalkian to early Adamanian. The common
89 conclusions of all this literature are that the Late Triassic Tiki Formation is dominantly Carnian
90 and its fauna can be correlated with the Lower Maleri fauna. So far, no evidence of a Norian age
91 was assigned to any part of the Tiki Formation. As stated earlier, based on the faunal pieces of
92 evidence and correlating it with the Late Triassic Maleri Formation of the Pranhita – Godavari
93 valley a Carnian age was assigned to the Tiki Formation ([Kutty et al. 1987](#); [Sengupta 1992](#); [Dutta &](#)

94 [Ghosh 1993](#)). Henceforth, through Decades, the Tiki formation was considered to be coeval with
95 the Carnian Maleri Formation ([Veevers & Tewari 1995](#); [Sengupta 1992](#); [Mukhopadhyay et al. 2010](#)).
96 Only recently, ([Datta et al. 2021b](#)) while describing a new phytosaur from the Tiki Formation,
97 commented that the age of the Tiki Formation may range from Carnian to early/Middle Norian.
98 To date, the faunal assemblage of the Tiki Formation includes fishes belonging to the family
99 Ceratodontidae, Hybodontidae and new undescribed forms of Xenacanthidae ([Ray et al. 2016b](#)),
100 temnospondyl amphibians belonging to Metoposauridae; reptilian belonging to families
101 Rhynchosauridae, Rauisuchidae, Rhyncocephalia, Acrodanta, basal Saurischia, Dromatheridae,
102 and Traversodontidae. Mammaliaformes are also reported from the Tiki Formation ([Ray et al.](#)
103 [2016b](#); [Bandyopadhyay & Ray 2020b](#)). An updated list of the faunal list of the vertebrate fossils so
104 far excavated and reported from the Tiki Formation is provided in Table 2a and Table 2b.
105 The appearance of chigutisaurids in India is noted with the demise of the metoposaurs,
106 rhynchosaurids, and primitive phytosaurs. Large prosauropods also appeared during that time
107 ([Novas et al. 2010](#)). Those events were thought to demarcate India's Carnian – Norian boundary
108 ([Datta et al. 2021](#)). However, recent signatures of the pluvial event and its role in extinction might
109 shift this boundary to Carnian – mid-Carnian/Norian. The Maleri Formation starts with a 250-
110 meter-thick mudstone ([Kutty & Sengupta 1989](#); [Dasgupta et al. 2017](#)). At the top of the mudstone, a
111 sandy zone initiates the sand–mud alternations of Upper Maleri ([Kutty & Sengupta 1989](#)). This
112 sandy zone contains a maximum number of rhynchosaur fossils, abundant metoposaurids, and
113 unionids. The chigutisaurids in Maleri appear just above this sandy zone ([Sengupta 1995](#)) and no
114 rhynchosaurids or metoposaurids are known from that level (or above that). The occurrence of
115 chigutisaurids in Tiki is also restricted within a sandy zone which do not contain metoposaurids
116 or rhynchosaurids. Unionids are also present there but in lesser abundance than Maleri. Phytosaur

117 teeth are also present. This sandy horizon noticed in Maleri and Tiki has been stratigraphically
118 placed below the Carnian – mid-Carnian/ Norian boundary and may indicate the Carnian Pluvial
119 Episodes (CPE) in India.

120 **Materials used and overview of their preservation**

121 **Preservation of specimen RH01/Pal/CHQ/Tiki/15-**

122 Only the picture of the palate published in the paper (Kumar & Sharma 2019) (Fig: 1a, b) could be
123 studied. as mentioned in the paper ([Kumar & Sharma 2019](#)) the material could not be excavated
124 from the field. The photograph of the said publication was reproduced with permission of the
125 journal editor and a higher resolution image was reproduced for better clarity and study. The
126 palate is dorsoventrally elongated and slightly sheared. The edges of the palate are not well
127 preserved.

128 The new specimens with ISI numbers, ISI A 202 and the published specimen of ([Kumar & Sharma](#)
129 [2019](#)) RH01/Pal/CHQ/Tiki/15 were recovered from mudrocks at a distance of about 100 meters
130 from each other from the village of Tenduadh in the Late Triassic Tiki Formation. Thus, ISI A
131 202 and RH01/Pal/CHQ/Tiki/15 are now the two chigutisaurid individuals that are being
132 reported from the Tiki Formation for the first time.

133 **Preservation of specimen ISI A 202** - The skull along with a fragmentary clavicle, ISI A 202, is
134 poorly preserved (Fig: 2a,2b,3a,3b,4,5). Only the left half of the skull is preserved and the
135 specimen is heavily eroded. Thus, the ornaments are not well observed in all the areas. The upper
136 part of the parietal and postfrontal have coarse ridges and grooves preserved in them. The palate
137 ISI A 202/1, ISI A 202/3-5 (Fig: 3a,3b). The skull, its fragments and the clavicle, all have been
138 excavated from the same point in the location and were present together with the same individual
139 as the skull.

140 The electronic version of this article in Portable Document Format (PDF) will represent a
141 published work according to the International Commission on Zoological Nomenclature (ICZN),
142 and hence the new names contained in the electronic version are effectively published under that
143 Code from the electronic edition alone. This published work and the nomenclatural acts it
144 contains have been registered in ZooBank, the online registration system for the ICZN. The
145 ZooBank LSIDs (Life Science Identifiers) can be resolved and the associated information viewed
146 through any standard web browser by appending the LSID to the prefix <http://zoobank.org/>. The
147 LSID for this publication is urn:lsid:zoobank.org:pub:1B45D1E1-9FFE-421D-8060-
148 4174334A7EF4. The online version of this work is archived and available from the following
149 digital repositories: PeerJ, PubMed Central SCIE, and CLOCKSS.

150 Chigutisauridae from the Tiki Formation

151 Systematic Palaeontology

152 Temnospondyli [Zittel 1888](#)

153 Stereospondyli [Zittel 1888](#)

154 Chigutisauridae [Rusconi 1951](#)

155 *Compsocerops* [Sengupta 1995](#)

156 *Compsocerops tikiensis* sp. nov. (ISI A 202/1, ISI A 202/2, ISI A 202/3, ISI A 202/4, and ISI A
157 202/5, RH01/Pal/CHQ/Tiki/15) (Fig: 2.a, 2b)

158 **Type material:** ISI A 202/1 which comprises the left half of a skull roof, ISI A 202/2 – a
159 nearly complete clavicle and ISI A 202/3, ISI A 202/4, and ISI A 202/5 – broken parts of the
160 skull are the holotype. The holotype materials are housed in Geological Studies Unit, Indian
161 Statistical Institute, Kolkata, India (Fig: 2a, b).

162 **Paratypes:** ISI A 202/2, ISI A 202/3, ISI A 202/4 and ISI A 202/5,
163 RH01/Pal/CHQ/Tiki/15.

164 **Referred material:** A palate (RH01/Pal/CHQ/Tiki/15) previously assigned to a
165 metoposaurid by (Kumar & Sharma 2019) has been referred (Fig: 1a,b). The parabolic skull
166 outline, vaulted pterygoid, shape and proportion of the interpterygoid vacuities, wide and folded
167 palatine ramus of the pterygoid, and comparatively narrow cultriform process of the
168 parasphenoid in RH01/Pal/CHQ/Tiki/15 indicate that it is not a metoposaurid. The cultriform
169 process is wider than *Compsocerops cosgriffi* but narrower than any of the metoposaurids. This
170 palate is comparatively well preserved and bears definite characteristics of a chigutisaur as it
171 appears from the field photograph (Fig: 1a, b). Only the photograph of the palate is available for
172 study.

173 **Locality:** Southwest of the Village of Tenduadh (23°59'41" N; 81°25'02" E), just next to
174 the Barakachh - Beohari Road in the district of Shahdol, Madhya Pradesh, Central India.

175 **Etymology:** The new species of chigutisaur is named after the Late Triassic Tiki
176 Formation from where the specimen has been excavated and studied.

177 **Diagnosis of genus:** A chigutisaur temnospondyl identified as *Compsocerops* by the
178 presence of the following combination of characters: skull outline parabolic in shape, orbits
179 anteriorly placed, raised rim of the naris, presence of a well preserved conspicuous quadratojugal
180 projection, presence of squamosal horn (which though broken and eroded is recognizable), and
181 ill preserved postparietal horn (though ill preserved the presence of horns can be clearly
182 identified), well preserved vaulted pterygoid, long and narrow cultriform process of the
183 parasphenoid, dentigerous area restricted to the anterior portion of the palate, short and restricted

184 palatine dentition not reaching to the middle of the choana, wide ramus of the pterygoid with a
185 gentle fold, walls like quadrate ramus of the pterygoid, presence of postpterygoid process, typical
186 shape of the ramus of the pterygoid and that of the subtemporal vacuities, long dorsal process of
187 the clavicle with a distinct groove and bean-shaped cross section.

188 **Diagnosis of species:** The new species of *Compsocerops* is identified by the presence of
189 an inward curved process of the quadratojugal as opposed to the straight downward trending
190 process of the quadratojugal in *Compsocerops cosgriffi*, presence of vomerine foramen, shorter
191 and wider interpterygoid vacuities, wider subtemporal vacuities, the base of the interpterygoid
192 vacuities at the same level with the base of the subtemporal vacuity as opposed to *Compsocerops*
193 *cosgriffi* (where the base of the interpterygoid vacuity is lower than the base of the subtemporal
194 vacuity making the interpterygoid vacuities longer and slenderer in *Compsocerops cosgriffi*) and
195 wider cultriform process of the parasphenoid.

196 Description and comparative anatomy

197 *The skull roof* (Fig: 2a, b)

198 The dorsal part of the skull roof can only be studied in ISI A 202.

199 The skull roof is parabolic in shape with a broad and concave posterior part of the skull table.
200 Even though the anterior part of the skull roof is mostly broken, a major portion of the left orbit
201 is preserved. The orbit is subcircular in shape and bordered by the prefrontal, jugal, postfrontal
202 and postorbital. The orbit is located in the anterior half of the skull and is laterally placed. The
203 posterior and posterolateral part of the left external nares is also preserved. It can be understood
204 from the posterior outline of the external nares that they are oval. The external nares are located
205 very close to the anterior border of the skull roof. The posterior part of the external nares is thick

206 and raised. This character is noted in chigutisaurids and is found in *Pelorocephalus tenax*
207 ([Marsicano 1999](#)) and *Compsocerops cosgriffi* ([Sengupta 1995](#)). The supraorbital sensory canal in
208 the region of the naris is unusually deep around the posterolateral border of the naris which is
209 responsible for the thick and raised posterior part of the naris in the ISI A 202. This characteristic
210 feature has also been noted in *Compsocerops cosgriffi* ([Sengupta 1995](#)) where anteriorly the naris
211 is flushed with the skull roof. The entire disposition of the sensory sulci is not well preserved in
212 the specimen. Apart from the supraorbital sulcus, the presence of postorbital dermal sensory
213 sulcus through the postfrontal can be recognized by the deep continuous canal like structure in
214 these two bones. The infraorbital sulcus is visible in the maxilla but gradually becomes less
215 prominent as it enters the jugal to form the jugal lateral dermal sensory sulcus. Just like other
216 comparable chigutisaurids like *Keratobrachyops australis* ([Warren 1981](#)), *Siderops kehli* ([Warren](#)
217 [& Hutchinson 1983](#)), *Pelorocephalus tenax* ([Rusconi 1949](#); [Marsicano 1999](#)), *Compsocerops cosgriffi*
218 ([Sengupta 1995](#)) the lacrimal is absent in ISI A 202 and the maxilla enters the border of the
219 external nares. However, the anterior part of the skull is fragmentary and heavily eroded. The
220 better-preserved left side of the dorsal part of the skull roof consists of partially preserved
221 prefrontal, postfrontal, postorbital and supratemporal. The squamosal is broken at the posterior
222 part, and parietal, postparietal, tabular, jugal and quadratojugals are also partially preserved. The
223 surfaces of the bones are eroded in most places and ornamentations are poorly preserved. The
224 parietal is comparatively large, rectangular and broken along the midline. Coarse ridges and
225 grooves can be recognized from the anterior part of the parietal. Just as in *Compsocerops* the
226 postparietal of ISI A 202 (Fig: 2a, b) is much shorter in length than the parietal. The pineal
227 foramen is not preserved in the parietal. The suture of the postparietal with the tabular is
228 obliterated. The postparietal is broken and eroded along the midline and at its posterior part in

229 the region of the postparietal horn. The postparietal horn is broken in ISI A 202 (Fig: 2a, b).
230 However, there is clear evidence that the horns exist. Postparietal horns are the most
231 unambiguous synapomorphy of *Compsocerops*. It is preserved in *C. cosgriffi* ([Sengupta 1995](#)), *C.*
232 *sp.* ([Dias-da-Silva et al. 2012](#)) and *C. tikiensis*. These horns are not preserved in any other
233 chigutisaur (the relevant area is not preserved in *Siderops* though ([Warren & Hutchinson 1983](#)) and
234 *Koolasuchus* ([Warren et al. 1997](#)). The tabular is most likely to be in contact with the parietal
235 though that part is not very well preserved. The broad tabular–parietal contact is considered to be
236 a diagnostic character of *Compsocerops* ([Sengupta 1995](#)). The tabular horn is broken. This post-
237 quadratojugal process is robust and despite the very poor preservation of the skull in general, the
238 posterior quadratojugal process is well preserved. The shapes and sutural patterns of the posterior
239 left side of the skull are very similar to *Compsocerops cosgriffi*.

240 *The Palate* (Fig: 3a, b)

241 Kumar and Sharma 2019, (Fig: 1a, b) described the palate (RH01/Pal/CHQ/Tiki/15) as a
242 metoposaurid palate (Fig: 1a, b). However, no detailed osteological description or identifying
243 characters were described by the authors as to why the specimen was identified to be a
244 metoposaurid. The authors only described the palate to be the ‘dorsal’ part of a metoposaurid as
245 it has conical teeth present on the anterior part. However, this description is vague and of no
246 taxonomical significance whatsoever as all temnospondyls have conical teeth and both
247 chigutisaurids and metoposaurids have teeth and tusks in the anterior part of the skulls. Again,
248 dentition restricted to the anterior margin of the skull is a characteristic of all temnospondyls
249 with parabolic skulls. Additionally, ([Kumar & Sharma 2019](#)) grouped the palate collected from the
250 village of Tenduadh with the specimens of metoposaurid clavicle collected from the village of
251 Jora. This grouping is not viable as the two villages are approximately 12 kilometres apart from

252 each other and there is a probability that these two villages might be parts of the Upper and
253 Lower parts of the Tiki Formation and may even be of different ages as discussed later. The
254 specimen, as said in [Kumar and Sharma \(2019\)](#), was too friable and could not be excavated by
255 them. Thus, there is no option to study the specimen first-hand. Henceforth, the image of [Kumar
256 and Sharma \(2019\)](#), has been replicated into a high-resolution photograph with the required
257 permission from the editor of the Journal of the Palaeontological Society of India to study the
258 detail of the described specimen (RH01/Pal/CHQ/Tiki/15) (Fig: 1a, b).

259 The studied specimen is the palate of a temnospondyl and not the dorsal view of the skull as
260 erroneously stated by [Kumar and Sharma \(2019\)](#). The palate showed in the picture
261 (RH01/Pal/CHQ/Tiki/15) (Fig: 1a, b) has a distinct vaulted pterygoid, parabolic skull outline,
262 and comparatively narrow cultriform process than metoposaurids. The specimen
263 (RH01/Pal/CHQ/Tiki/15), ([Kumar and Sharma 2019](#)) (Fig: 1a, b) has a parabolic skull, thickening
264 of the pterygoid, presence of vaulted pterygoid, presence of post-pterygoid process and concave
265 vertical wall of pterygoid that are characteristic of chigutisaurids as written repeatedly above.
266 The specimen is indeed friable with dense networks of fractures that obscured the clear
267 identification of the sutures. The specimen (RH01/Pal/CHQ/Tiki/15) is partly eroded along the
268 lateral margins as well as anteriorly and posteriorly. The right half of the palate is slightly
269 compressed, deformed and curved (Fig: 1).

270 The anterior portion of the palate is considerably broken both anteriorly and anterolaterally.
271 Though the sutures cannot be delineated, the presence of vomer is very apparent. The vomer is
272 broken anteriorly and the anterior palatal vacuity is not preserved (RH01/Pal/CHQ/Tiki/15) (Fig:
273 1). The posterior part of the preserved vomer includes the anterior tongue of the cultriform
274 process of the parasphenoid. The left half of a possible vomerine cavity is preserved. The

275 vomerine cavity is present only in Jurassic chigutisaur *Siderops kehli* ([Warren and Hutchison](#)
276 [1983](#)) and it is absent in *Compsocerops* (Sengupta 1995) or *Pelorocephalus* ([Marsicano 1999](#)).
277 The left lateral margin of the right choana is aligned to the left lateral margin of the right
278 interpterygoid vacuity. The ectopterygoids are exposed on the anterolateral margins of the
279 interpterygoid vacuities and are preserved on both sides. The ectopterygoid borders the anterior
280 portion of the subtemporal vacuity inwards. The subtemporal vacuity is wide and broad bordered
281 by the ectopterygoid and the parasphenoid on the inward margin and the quadratojugal, the alar
282 process of the jugal on the outward lateral margin. The dentigerous area is restricted to the
283 anterior region of the palate. The anterior and the anterolateral margins of the palate are broken,
284 and all teeth are not preserved. However, two broken ectopterygoid teeth can be seen preserved
285 at the anterolateral corner of the ectopterygoid in contact with the palatine in the left part of the
286 palate. The palatine teeth row in the left half of the skull is also preserved partially. Like other
287 chigutisaurids, the dentigerous area of the palate is remarkably short. The palatine row of teeth is
288 not continuous up to the middle of the choana. This character has been considered to be a
289 synapomorphy of *Compsocerops cosgriffi* ([Sengupta 1995](#)). Conical, inward curved four complete
290 palatine teeth are preserved in the margin of the left palatine bone of the palate. Since, the
291 dentigerous area is restricted to the anterior part of the skull the posterior part is longer in
292 proportion and covered by large and wide subtemporal vacuity (Fig: 3a, b).

293 In (RH01/Pal/CHQ/Tiki/15) (Fig: 1a, b) ([Kumar and Sharma 2019](#)) both the interpterygoid
294 vacuities are well preserved. The interpterygoid vacuities are quadrangular in shape, shorter and
295 wider compared to *Compsocerops cosgriffi* ([Sengupta 1995](#)). The borders of the interpterygoid
296 vacuities are approximately parallel sided. The interpterygoid vacuities are bordered dominantly
297 by the cultriform process along the inward margin as well as the vomer. Anteriorly, it is

298 bordered by the vomer and the palatine. The pterygoid forms the dominant margin of the
299 interpterygoid vacuities laterally with a small area being occupied by the ectopterygoid.
300 Posteriorly, these are formed by the parasphenoid. In ISI A 202/1, the interpterygoid vacuities
301 are not completely preserved. In both, the specimens ISI A 202 and (RH01/Pal/CHQ/Tiki/15)
302 ([Kumar and Sharma 2019](#)), the interpterygoid vacuities are shorter and broader than *Compsocerops*
303 *cosgriffi* where the base levels of the interpterygoid vacuities are lower than that of the
304 subtemporal vacuities. The subtemporal vacuity extends anteriorly to the level higher than the
305 centre of the interpterygoid vacuities.

306 In (RH01/Pal/CHQ/Tiki/15) ([Kumar and Sharma 2019](#)) (Fig: 1a, b) both the pterygoids are
307 preserved. They are deep and vaulted. The vertical lateral wall of the pterygoid projects
308 posteriorly possibly up to the posterior level of the occipital condyles which are broken. The
309 palatal ramus of the pterygoid is visible on both sides in (RH01/Pal/CHQ/Tiki/15). The palatal
310 ramus of the pterygoid is longitudinally concave with a gentle fold which is again a character of
311 some chigutisaurids specially *Compsocerops*. The quadrate ramus of the pterygoid is better
312 preserved on the right side of the palate (RH01/Pal/CHQ/Tiki/15). The quadrate ramus of the
313 pterygoid looks like a wall as they are deeply vaulted. The ascending ramus of the pterygoid is
314 not visible in (RH01/Pal/CHQ/Tiki/15). A broken post pterygoid process that is a projection
315 from the posterior border of the pterygoid corpus is visible on the right side of the palate
316 (RH01/Pal/CHQ/Tiki/15). This area on the left side of the palate of (RH01/Pal/CHQ/Tiki/15) is
317 broken. The postpterygoid process is considered to be an apomorphic character for
318 *Compsocerops cosgriffi* ([Marsicano 1999](#)). The suture of the quadrate and pterygoid is present on
319 the outer side of the downturned part of the quadrate ramus of the pterygoid. In ISI A 202, (Fig:
320 3a, b) only the right pterygoid is ill-preserved but the bone surface is crushed. However, a

321 distinct post pterygoid process characteristic of *Compsocerops* is present. Though the bone is
322 crushed and compressed, the vaulted nature of the pterygoid can be made out because of the
323 concavity of the vertical wall of the pterygoid. In both, the specimens (RH01/Pal/CHQ/Tiki/15)
324 ([Kumar and Sharma 2019](#)) and ISI A 202, the palatine ramus of the pterygoid is much broader and
325 wider than that in *Compsocerops cosgriffi*.

326 Just like other chigutisaurids, the base of the parasphenoid is almost hexagonal with a long
327 extension in the form of the cultriform process placed between two interpterygoid vacuities in
328 (RH01/Pal/CHQ/Tiki/15) ([Kumar and Sharma 2019](#)). The parasphenoid has a long suture with the
329 pterygoid laterally and the exoccipitals posteriorly. A distinct raised longitudinal keel is present
330 on the ventral surface of the cultriform process in this specimen. The presence of this keel in the
331 cultriform process has been noted by [Marsicano \(1999\)](#) as a distinguishing character present only
332 in *Pelorocephalus mendozensis*. However, first-hand studies reveal that this longitudinal keel of
333 the cultriform process is also present in *Compsocerops cosgriffi* from the Maleri Formation of
334 Pranhita - Godavari Valley Basin. The cultriform process of parasphenoid of this specimen is
335 comparatively narrower than all other specimens of *Compsocerops cosgriffi*. The cultriform
336 process of the *Compsocerops* species from Tiki is wider than *C. cosgriffi*, the cultriform process
337 is also comparatively broader than *Siderops kehli*, more comparable to the width of the
338 cultriform process in the specimen previously denoted as *Kuttycephalus triangularis* ([Sengupta](#)
339 [1995](#)). The cultriform process preserved in (RH01/Pal/CHQ/Tiki/15) ([Kumar and Sharma 2019](#)) is
340 thin and constricted in the middle part of the interpterygoid vacuities and gets broader as it
341 progresses to the anterior part of the process. This type of cultriform process is unique among the
342 chigutisaurids. In the specimen photographed by [Kumar and Sharma \(2019\)](#), the anterior tongue of
343 the cultriform process is in contact with the vomer and lies posterior to the level of the anterior

344 margin of the interpterygoid vacuities. The cultriform process is not preserved in ISI A 202. The
345 occipital condyles are broken as well. In the earliest known chigutisaur *Keratobrachyops*, the
346 cultriform process of the parasphenoid is also narrower than ISI A 202.

347 *The Occiput* (Fig: 4)

348 The occiput is very ill preserved only in ISI A 202 (Fig: 4). The occiput could not be prepared
349 due to the extremely fragile nature of the skull. Removing the matrix load from the occiput
350 would result in the sagging of the entire specimen. However, from the little that could be studied,
351 it can be said that in occipital view, the quadrate ramus of the pterygoid is deeply downturned.
352 The vagus nerve foramen is preserved on the left exoccipital lateral to the broken occipital
353 condyle. The ascending process of the exoccipital is wide and inclined and meets the descending
354 process of the postparietal. A sub-circular, matrix filled, paraquadrate foramen is present in the
355 quadratojugal. The quadrate is partially preserved in the occipital view. It is bounded by the
356 squamosal, quadratojugal and the downturned pterygoid. The absence of occiput makes the
357 comparison of ISI A 202 difficult with the different species of *Pelorocephalus* as different
358 species of the genus are differentiated, to a great extent, by their occipital characters (Marsicano
359 1999).

360 *Clavicle* (Fig: 5)

361 An almost complete left clavicle (ISI A 202/2) (Fig: 5) was found associated with the skull (ISI
362 A 202/1) during excavation. The clavicle has a flat eye-drop shaped blade and a long straight
363 dorsal process that ascends almost straight, nearly at ninety degrees with the plate. The cross-
364 section of the process at the dorsal end is bean shaped as a feeble furrow runs along the process.

365 This is very similar to the clavicle of *Compsocerops cosgriffi* ([Sengupta 1995](#)), *Siderops kehli*
366 ([Warren and Hutchinson 1983](#)) and *Koolasuchus cleelandi* ([Warren et al. 1997](#)).

367 The Carnian Pluvial Episode – A Global Climatic Consequence

368 The Carnian Pluvial Episode (CPE) can be defined as a geologically short-lived (234-232
369 Million years ago) monsoonal period of extreme rainfall that brought about significant changes
370 in several depositional environments ([Schlager & Schöllnberger 1974](#); [Simms & Ruffell 1990](#); [Furin et](#)
371 [al. 2006](#); [Arche & Lopez-Gomez 2014](#); [Dal Corso et al. 2015](#)). The Carnian Pluvial Episode was a
372 global phenomenon. Geochemical data suggest that global warming involved environmental and
373 biotic changes. Radioisotopic ages coupled with biostratigraphic correlation suggest a possible
374 link to the eruption of the Wrangellia Large Igneous Province (LIP) ([Dal Corso et al. 2020](#)). CPE
375 was a significant (but previously neglected) time of extinction linked to the Carnian explosive
376 diversification of many key modern groups of plants and animals ([Dal Corso et al. 2020](#)). The CPE
377 marks a distinct change in the hydrological cycle during which the climate shifted from arid to
378 humid conditions and back again to arid conditions ([Bernardi et al. 2018](#)). It is represented by
379 remarkable enhancement of the hydrological cycle demarcated by four episodes of increased
380 rainfall indicated by diverse sedimentary and paleontological data, repeated Carbon Cycle
381 perturbations, evidenced by sharp negative C-isotope excursions, coincided with global
382 environmental changes and climate warming all of which suggest a cause and effect relationship
383 ([Dal Corso et al. 2015](#), [Dal Corso et al. 2020](#)).

384 The Carnian is the earliest part of the Late Triassic and its base or lower boundary is dated at
385 approximately 237 million years based on U-Pb radiometric dating of a single crystal zircon
386 from a tuff layer within a section having strong biostratigraphic constraints ([Corso et al. 2012](#); [Dal](#)
387 [Corso et al. 2015](#); [Dal](#); [Maron et al. 2019](#)). The upper boundary of the Carnian is constrained at

388 approximately 227 million years based on magnetostratigraphic correlations between the marine
389 successions of Tethys and the astrochronological time scale of the continental Newark Basin
390 ([Kent et al. 2017](#)). The Carnian is subdivided into Julian (Early Carnian) and Tuvalian (Late
391 Carnian) substages. The Julian – Tuvalian boundary occurs at approximately 233 million years
392 ([Dal Corso et al. 2015](#); [Kent et al. 2017](#); [Dal Corso et al. 2020](#)). The beginning of the onset of CPE is
393 well defined from ammonoid, conodont, and sporomorph biostratigraphic dating and
394 synchronous in several geological settings. It coincides with the first appearance of the
395 ammonoid genus *Austrotrachyceras* in the Julian ([Simms & Ruffell 1990](#); [Roghi et al. 2010](#); [Dal Corso](#)
396 [et al. 2020](#); [Dal Corso et al. 2012](#); [Dal Corso et al. 2015](#); [Sun et al. 2016](#)). However, the upper
397 boundary or the end of CPE is poorly defined in most locations. It is usually placed at the base or
398 within the Tuvalian 2 based on sedimentological (e.g., end of terrigenous sediment supply) and
399 chemostratigraphic (last C-isotope excursion) evidence ([Dal Corso et al. 2015](#); [Dal Corso et al. 2018](#);
400 [Dal Corso et al. 2020](#)). The total duration of this pluvial episode is variable. Cyclostratigraphy of
401 marine successions of the South China Block and continental successions of the Wessex Basin
402 (United Kingdom) gives a duration of the CPE of approximately 1.2 ma but this is variable and
403 longer to 1.6-1.7 million years as indicated by integrated stratigraphy (biostratigraphy and
404 magnetostratigraphy).

405 **Significance of temnospondyl amphibians in the Carnian Pluvial Episode**

406 The CPE facilitated the Dinosaur Diversification Event (DDE) ([Bernardi et al. 2018](#)). But the role
407 of CPE on the temnospondyls has not much been discussed barring a few papers ([Buffa et al.](#)
408 [2019](#); [Fortuny et al. 2019](#); [Lucas 2020](#); [Gee & Jasinski 2021b](#)). The amphibious temnospondyls living
409 both on land and water were the most sensitive to the changes in climate. Two dominant groups
410 of temnospondyls, in this context, were the metoposaurids and the chigutisaurids. According to

411 ([Fortuny et al. 2019](#)) the gigantism of the metoposaurids might have been linked to the Carnian
412 Pluvial Episode. ([Buffa et al. 2019](#)) also stated that the diversification of the metoposaurids might
413 have been linked to the CPE and the post CPE aridification led to the extinction of the
414 metoposaurids during the Rhaetian. ([Gee & Jasinski 2021a](#)) have also commented on the fact that
415 the physiological variation of the metoposauridae and their palaeoclimatic range also
416 corroborates a palaeo-environmental barrier. Finally, ([Lucas 2020](#)) concluded that climate change
417 that occurred during CPE played an important part in the metoposaurid evolution. According to
418 [Lucas \(2020\)](#), Metoposaurids appeared during the CPE, attained their highest diversity and
419 cosmopolitan distribution during this time and had reduced diversity and showed endemism in
420 the post CPE climate.

421 [Significance of *Compsocerops tikiensis* in demarcating the Carnian Pluvial](#) 422 [Episode \(CPE\) in India.](#)

423 The presence of *Compsocerops* in both Maleri and Tiki Formation enhances the scope to discuss
424 the palaeoenvironment of these two Late Triassic basins in India and to compare the possible
425 reason for faunal turnover from Carnian to Norian ([Sengupta 1995](#)) concerning the amphibious
426 temnospondyls.

427 In the light of the newly excavated chigutisaurid *C. tikiensis*, the faunal changeover in the Tiki
428 Formation is now more apparent and as follows:

429 [Tiki Formation](#)

430 No detailed sedimentological or geochemical studies have been carried out in the Late Triassic
431 Tiki Formation in India to analyse the associated changes from Carnian to Norian through the
432 humid phase of the Carnian Pluvial Episode. Though, ([Ahmed & Ray 2010](#)) presented a
433 geochemical analysis of 42 nodular carbonates confirming their pedogenic origin, no details of

434 the localities of collection in terms of lower and upper Tiki have been provided. The map of the
435 temnospondyl bearing localities of the Tiki Formation has been modified here with faunal
436 boundaries (hypothetical faunal boundary demarcated in red dotted line) after [Mukherjee et al.](#)
437 [\(2012\)](#) (Fig: 6). Till date, no temnospondyl fauna has been recorded from the upper part Tiki
438 Formation. Excavation taken up in 2018 revealed the first chigutisaurid from the Tiki Formation
439 in the Tenduadh locality (Fig: 7) in the upper part of the Tiki Formation. Several vertebrae and
440 postcranial bones of metoposaurid have been excavated from the Jora and Tiki Nala sections
441 which have been assigned to the lower Tiki Formation

442 Based on the changes in the faunal assemblage in the lower and the upper Tiki Formation and
443 considering the lithostratigraphy, a boundary between the basal and upper Tiki Formation has
444 been assigned and the zone demarcating the Carnian to Norian faunal turnover in the Tiki
445 Formation has been approximated and marked in red dotted line in the map (Fig: 6).

446 The lithological logs modified after [Kumar and Sharma \(2019\)](#) and [Mukherjee et al. \(2012\)](#) reveal
447 that just like the Maleri Formation, the basal Tiki Formation is dominated by a large band of red
448 mudrock intercalated with peloidal calcirudite-calcarenite ([Sarkar 1988](#)) (Fig: 8). The Jora Nala
449 section in the Carnian basal Tiki has been logged in detail in this work (Fig:8a). This shows the
450 dominance of greenish to reddish siltstones and mudstones in the Jora Nala section with sparse
451 deposition of trough cross-bedded sandstones in between. The terrestrial influx of sediments is
452 significantly low at that period as denoted by the sparse occurrence of sandstones in the basal
453 Tiki Formation (Fig: 8a, b,c). The presence of Unio beds in between the basal thick layers of
454 mud (Fig: 9) reflects a stagnant quiet and well-watered environment. This basal mud
455 encompasses areas like the Jora and Tiki River sections. Abundant postcranial fragments of
456 metoposaurids and rhynchosaurs have been collected from these sections. Moving upwards in

457 the direction of the dip of the beds, there is a sudden influx of siliciclastic sediments marked by
458 thick sandstone units with little intermittent mudstone. This could be a demarcation of the rapid
459 influx of siliciclastic sediments that took place during CPE in the Tiki Formation. Only two
460 dominant sand bodies are observed in Tiki before the recurrence of a thick horizon of mud and
461 subsequently sand-mud alternations indicating the onset of seasonality and aridity in the Norian
462 (Fig: 9). The Norian of Tiki Formation is demarcated by red mudstones, whitish sandstones and
463 sparse calcirudites. The Norian Upper Tiki Formation is exposed in sections near Tenduadh as
464 shown in the map (Fig: 6) and an estimated approximate faunal boundary between the Carnian
465 and the Norian in the Tiki Formation is also furnished as in Fig: 6.

466 Tiki has a long history of yielding fossil vertebrates ([Chatterjee & Roy-Chowdhury 1974](#);
467 [Bandyopadhyay & Ray 2020b](#)) (Table 1). It has a rich Late Triassic faunal association marked by
468 different taxa of Chondrichthyes and Osteichthyes fishes, a metoposaur *Panthesaurus*, a
469 phytosaur *Volcanosuchus* belonging to the subfamily Mystriosuchinae and leptosuchomorphs, a
470 rhynchosaur *Hyperodapedon tikiensis*, a rauisuchid named *Tikisuchus*, cynodonts and
471 mammaliaformes taxa among others ([Chatterjee & Majumdar 1987](#); [Bandyopadhyay & Ray 2020b](#);
472 [Mukherjee & Ray 2014](#)). The Tiki faunal assemblage was thought to be coeval to the Lower Maleri
473 faunal assemblage ([Kutty & Sengupta 1989](#); [Datta 2005](#)). However, [Datta et al. \(2019\)](#) stated that the
474 Tiki fauna ranges from Middle Carnian to Early Norian and is younger than Lower Maleri
475 Fauna. The mid Carnian / Norian Upper Maleri fauna has chigutisaurids. The Discovery of a
476 chigutisaurid from the upper part of the Tiki Formation confirms [Datta et al. \(2019\)](#) regarding the
477 presence of Middle Carnian / Norian fauna in the Tiki Formation. The presence of
478 *Compsocerops* in Tiki, for the first time, confirms the presence of the Upper Maleri faunal
479 element in Tiki. ([Lucas 2020](#)) thought that the demise of metoposaurids in most parts of the world

480 was at the end of Carnian and that tallies with the last appearance datum of the metoposaurids of
481 Maleri. The chigutisaurids, both in Maleri and Tiki have their first appearance datum at the onset
482 of the Middle Carnian or Early Norian.

483 Maleri Formation

484 The overall palaeoenvironment and sedimentology of the Maleri formation have been worked
485 upon by several workers ([Sarkar 1988](#); [Dasgupta & Ghosh 2018](#)). Most of these studies were done
486 on the Maleri Formation as a whole without distinguishing its basal and upper parts. However,
487 no detailed analyses about the changes in sedimentology or geology or geochemistry have been
488 done to study the changes in the pattern of sedimentation from the Carnian basal Maleri to the
489 Norian Upper Maleri.

490 The temnospondyl bearing (metoposaurid and chigutisaurid) localities of the Maleri Formation
491 have been extensively mapped and modified after ([Kutty & Sengupta 1989](#); [Dasgupta et al. 2017](#))
492 (Fig: 10) and a boundary between the Carnian basal Maleri and Middle Carnian / Norian Upper
493 Maleri has been established from both lithological and faunal contents (Fig: 10 – faunal
494 boundary indicated by a green broken line). From the field studies and maps it is evident that
495 though sandstone - mudstone alternation is present throughout the Maleri Formation, the Carnian
496 basal Maleri is abundant in red mudrocks and calcirudites (Fig: 10,11) and moving towards
497 Upper Maleri there is a sudden increase in the deposition on siliciclastic sediments leading to the
498 more frequent occurrence of sandstone bands alternating with red mudstone (Fig: 11). The
499 abundance of red mudstone in basal Maleri Formation (Fig: 12) with a sudden increase in the
500 frequency of sandstone bands in the upper part can be correlated with the advent of the Carnian
501 Pluvial Episode (CPE) in India. The CPE had a significant impact on the terrestrial environment

502 and ecosystem globally. The evidence of CPE has never been worked upon or mentioned in India
503 because of the lack of proper age constraints present in the Late Triassic Formations in India,
504 both in the Maleri and Tiki Formations. However, evidence from detailed geological mapping,
505 logs and associated faunal turnover in the Late Triassic Maleri Formation all point toward the
506 distinctive effect of CPE in India. The overall thickness of the Maleri Formation is about 350-
507 600 m which is variable in different places. From the map of the Maleri Formation and log of the
508 same near Achlapur and Nalapur (Fig: 11), it is evident that the basal part of the Maleri
509 Formation has a large stretch or band of red mudrock dominated unit. This unit of red mudrock
510 stretches from about 100m- 200m in thickness in basal Maleri and is the thickest band of red
511 mudrock encountered in the entire Maleri Formation. It encompasses villages namely
512 Aigerrapalli (19°15'22.4" N; 79°27'23.4" E), Achlapur (19°09'34" N; 79°31'51" E) and
513 Nambala (19°13'47" N; 79°26'07" E), areas slightly north of village Gampalpalli (19°10'11" N;
514 79°30'53" E) and is rich in vertebrate fossils, the most significant among them being
515 rhynchosaurus and metoposaurids. This significantly thick basal Maleri mudstone has sporadic
516 carbonate grainstones (*sensu* [Dunham 1962](#)); calcarenites–calcirudites of [Sarkar 1988](#)) and the
517 presence of palaeosols with no significant siliciclastic deposition of sandstone present within this
518 mud. The upper part of the Formation is approximately 200–350 m thick and has three to four
519 multi-storeyed sheet sandstone bodies (each 10–35 m thick) vertically separated by mudrock
520 dominated intervals (15–55 m thick). The mudrock intervals in the upper part are lithologically
521 similar to those occurring in the lower part of the Formation. The mudrock units comprise both
522 stratified and massive mudstones ([Dasgupta et al. 2017](#)) with sporadic carbonate grainstones
523 (calcirudite of [Sarkar 1988](#)). Moving upwards from the thick stretch of mudrock, the influx of
524 siliciclastic sedimentation increases as evident from the increase in the deposition of frequent

525 sandstone units. The beginning of these sandstone units is marked by the presence of
526 metoposaurids and rhynchosaurs and unionid fossils in a sandy zone. In the upper part, apart
527 from the chigutisaurids, there are basal sauropods like *Jaklapallisaurus*, and sauropodomorphs
528 like *Nambalia*, probable Guaibasaurids and *Herrerasaurus* like forms (Novas et al. 2010). The
529 authors in the same work, also mentioned that early theropods are known from the Norian-
530 Rhaetian time from North and South America, India, South Africa, and Europe and the demise of
531 members of Lower Maleri fauna like rhynchosaurs together with the global extinction of
532 *Chiniquodon* (cynodont) and Proterocampsidae (archosauriform) mark the Carnian – Norian
533 boundary and also the North Tethyan Pluvial Event of end Carnian (CPE). [Benton et al. \(2018\)](#)
534 have argued that CPE triggered the diversification of early dinosaurs. It has been discussed
535 earlier those indications of CPE are present in Maleri and Tiki Formations of India. The sudden
536 appearance of several basal dinosaurs like *Jaklapallisaurus*, *Nambalia*, probable Guaibasauridae
537 and *Herrerasaurus* ([Novas et al. 2010](#)) in the Norian Upper Maleri fauna also corresponds to that.

538 Thus, the palaeoenvironment of the Maleri Formation shifted from a comparatively arid and dry
539 climate in the Julian at the basal substage of Carnian to a high competence fluvial-lacustrine
540 environment with the presence of small, ephemeral and vegetated swamps or ponds along the flow
541 path of the channels at the time of Carnian Pluvial Episode from the end of Julian to Tuvlian and
542 back again to fluvial deposition in the Norian ([Dasgupta et al. 2017](#)). The episodes of increased
543 rainfall during the Carnian Pluvial Episode demarcated by increased frequency of sandstone
544 deposition are intervened by seasonality as evident from the red mudrock alternations between
545 sandstones. Similar climatic shifts are seen from the coeval Santa Maria to Caturrita formations
546 of Brazil ([Dal Corso et al. 2015](#)). These shifts indicating a major variation of the hydrological regime
547 in terrestrial depositional settings suggest an enhancement of the hydrological cycle during the

548 CPE. Recently, [Lucas \(2010\)](#) stated that the demise of metoposaurids in most parts of the world
549 during the Carnian is related to the end of the enhanced hydrological cycle at the dying phase of
550 CPE. The disappearance of key herbivorous groups such as dicynodonts and rhynchosaurs of
551 Carnian and their places taken up by giant sauropodomorphs seems to be linked to CPE which is
552 not documented in India so far.

553 Also, the *Hyperodepadon* Assemblage Zone (HAZ) is characterized by the presence of
554 rhynchosaur *Hyperodepadon* and is present in the lower part of the Ischigualasto Formation of
555 Argentina, the Lossiemouth Sandstone Formation of Scotland, and the Lower Maleri Formation
556 of India ([Langer et al. 2010](#)). The HAZ is dated as late Carnian to early Norian, approx. 228–224
557 Ma by some authors ([Brusatte et al. 2010](#); [Ezcurra et al. 2017](#); [Benton et al. 2018](#)). Most metoposaurids
558 in the Gondwana deposits are considered to be Carnian in age ([Chakravorti & Sengupta 2019](#); [Gee &](#)
559 [Jasinski 2021b](#); [Sengupta 2002](#)). The demise of the metoposaurids *Panthsaurus maleriensis*
560 ([Chakravorti & Sengupta 2019](#)) in India along with the demise of *Hyperodepadon* in both Late
561 Triassic Maleri and Tiki Formation also points to the presence and effect of CPE in India. The
562 demise of the metoposaurids left a vacant niche to be occupied by the chigutisaurids in the Norian
563 suggesting short lived aridity in post Carnian stage.

564 The Effect of CPE on the terrestrial ecosystem of Maleri and Tiki 565 Formations

566 The Carnian of Argentina has its age radiometrically constrained between 231.4 ± 0.3 and 225.9
567 ± 0.9 Ma ([Martínez et al. 2016](#)) and similar reports are present from Santa Maria and Caturrita
568 Formations of Brazil (233.2 ± 0.7 and 225.4 ± 0.4 Ma) ([Langer et al. 2018](#)). The onset of CPE is
569 well constrained in stratigraphic sections like the Southern Alps of Italy, Northern Calcareous Alps
570 of Austria, Transdanubian Range of Hungary, and the Nanpanjiang Basin of the South China block

571 and is placed at the substages Julian 1 – Julian 2 boundary of the Carnian ([Gallet et al. 1994](#), [Dal](#)
572 [Corso et al. 2016](#)). Due to the lack of any radiometric dating, Late Triassic Maleri and Tiki
573 Formations are poorly constrained and pose difficulty in global correlation, their correlation is
574 based only on available fauna. The CPE has always been dated as mid-Carnian ([Ruffell et al. 2016](#))
575 but this is not a unanimous viewpoint. The Italian Dolomites occur between the
576 Aonoides/Austriacum interval (about Julian) and the base of the Subbullatus Zone (Tuvalian),
577 dated at 234–232 Ma ([Roghi et al. 2010](#); [Dal Corso et al. 2015](#)). The further constraint has been
578 documented in borehole successions in the southwest UK, which indicates a maximum duration
579 of 1.09 MYA ([Miller et al. 2017](#)). The precise radiometric dating to constrain the Maleri and Tiki
580 Formations and to denote the beginning of CPE in India will shed further light on the pattern of
581 faunal diversification post CPE event in the subcontinent and help in the global stratigraphic
582 correlation. A continental carbon isotope record in southwest England shows multiple carbon cycle
583 perturbations during CPE ([Miller et al. 2017](#)). The CPE is not only the time interval of increased
584 humidity but also a major carbon perturbation ([Dal Corso et al. 2016](#)). Unfortunately, no carbon
585 isotope data is noted from the Maleri and the Tiki Formations of India.

586 Conclusion

- 587 1. In the current work a new species of chigutisarid amphibian, *Compsocerops tikiensis*
588 from the Late Triassic Tiki Formation of the Rewa Gondwana Basin has been described
589 in detail. The presence of chigutisaurid *Compsocerops tikiensis* in the Upper part of the
590 Tiki Formation is the first evidence of the Norian chigutisaurid amphibian from the said
591 Formation and is important for correlation of the Late Triassic basins worldwide.
- 592 2. Along with the extinction of the rhyncosaurs and *Parasuchus* (primitive phytosaur),
593 chiniquodontids (cynodonts), the Carnian – Norian Extinction Event (CNEE) also caused

594 the extinction of the metoposaurids in India. Chigutisaurids appeared in Middle Carnian /
595 Norian and India is the only place which accommodates definite metoposaurids and
596 chigutisaurids within the same formations (the Late Triassic Maleri and Tiki Formations)
597 the former being replaced by the latter. Incidentally, among the phytosaurs, the
598 *Parasuchus* of Lower Maleri fauna is replaced by the *Leptosuchus* like forms of Upper
599 Maleri and *Volcanosuchus statisticae* in the upper part of the Tiki Formation.

600 3. The post-CNEE empty niche left by the metoposaurids in the Late Triassic Gondwana
601 deposits of India (controversially Brazil as well, see ([Dias-da-Silva et al. 2011](#)) was
602 occupied by the chigutisaurids in the Norian. The availability of phytosaur teeth along
603 with *C. tikiensis* only indicated their co-existence in the same aquatic niche but does not
604 necessarily point towards any prey-predatory relationship between the phytosaurids and
605 the chigutisaurids. However, detailed studies on histology and growth pattern of the
606 chigutisaurids might shed light on the gigantism of these amphibious animals in the post-
607 CNEE and recovery of the temnospondyls.

608 4. The presence of both metoposaurids and chigutisaurids and the faunal turnover from the
609 Carnian to the Norian along with the extinction of the rhynchosaurs (*Hyperodapedon*)
610 and *Parasuchus* in the Carnian of both the Late Triassic Maleri and Tiki Formation and
611 the presence of prosauropods in the Upper Maleri Formation and undescribed
612 dinosauriformes including theropod-like forms ([Bandyopadhyay & Ray 2020b](#)) sheds light
613 and documents for the first time the existence and effect of the Carnian Pluvial Episode
614 in India.

615 5. The finding of *Compsocerops tikiensis* from the Tiki Formation and assessing its
616 importance in global palaeoclimatic and palaeoclimatic correlation paves the way for

617 future scope of works in finding the effect of CPE in India and comparing its faunal
618 diversification at a global scale. Also, finding any new and better-preserved specimen of
619 *Compsocerops tikiensis* from the Tiki Formation would help to establish the phylogenetic
620 relationship of the other chigutisaurids around the world with that of the Indian
621 counterparts. As the specimens are deformed broken and have poor preservation
622 potential, phylogenetic analysis is beyond the scope of this paper as it will add more
623 missing and misinterpreted data.

624 Acknowledgements

625 The authors SC and DPS would like to acknowledge the Indian Statistical Institute, Kolkata for
626 funding the field work and excavation of this specimen. The author SC would like to thank Ms.
627 Aindrila Roy, Project Linked Person (PLP) at the Geological Studies Unit, Indian Statistical
628 Institute, Kolkata for her help in editing the manuscript. The authors SC and DPS would like to
629 acknowledge Mr Lakshman Mahankur for helping in the preparation of the poorly preserved
630 material. We acknowledge the editor (Surendra Kumar) of the Journal of Palaeontological
631 Society of India for providing us with the permission to reproduce the picture published on page
632 159, (Plate IV. number 1) of the journal volume 64(2), December 31, 2019. We are also very
633 grateful to Dr Claudia Marsicano, Dr Valentin Buffa and the anonymous reviewer who through
634 their insightful comment and meticulous suggestions has enriched this work to a great extent.

Table 1 (on next page)

Spatial and temporal range of the family Chigutisauridae along with their paleoecology and paleoenvironment.

Abbreviations Max ma = Maximum age million years ago, Min ma = Minimum age million years ago, Fm. = Geological Formations from which the specimen had been excavated. The table has been modified after data was acquired from the Paleobiology Database on 10th May 2022, using the family name "Chigutisauridae". Data for the table was modified after Bonaparte 1957; Marsicano 1999; Dias - da- Silva and Sengupta 2012; Warren 2006; Pledge 2013; Cabrera 1944; Rusconi 1949; Rusconi 1951; Sengupta 1995; Warren and Hutchinson 1983; Warren 1981; Warren and Marsicano 2000)

1 Table 1

Name	Early_interval	Late_interval	Max_ma	Min_ma	Country	Fm.	Lithology	Palaeoenvironm
<i>Koolasuchus cleelandi</i>	Late Aptian	–	122.46	112.03	Australia	Eumeralla Fm.	Sandstone	
<i>Koolasuchus cleelandi</i>	Late Aptian	–	122.46	112.03	Australia	Eumeralla Fm.	Sandstone

6

7 Table 2b

Order/Family	Genus and Species	Order/Family	Genus and Species
--------------	-------------------	--------------	-------------------

AMPHIBIA		DIAPSIDA	
Metoposauridae	<i>Panthisaurus maleriensis</i>	Archosauriformes	<i>Galtonia sp.</i> , <i>Protecovasaurus sp.</i> , and other intermediate forms
Chigutisauridae	<i>Compsocerops tikiensis</i>	Dinosauriformes	Undescribed Theropod-like (?) forms
DIAPSIDA		Aetosauria	Undescribed
Phytosauria	<i>Volcanosuchus statisticae(?) leptosuchomorph</i>	SYNAPSIDA	
Rhynchosauria	<i>Hyperodapedon tikiensis</i>	Cynodontia	<i>Ruberodon roychowdhurii</i>
Rauisuchidae	<i>Tikusuchus romeri</i>	Mammaliaformes	<i>Tikitherium copei</i>
Rhynchocephalia	<i>Undescribed</i>		<i>Gondwanadon tapani</i>

8 Table- 2b: Vertebrate fossil assemblage (tetrapod content) of the Late Triassic Tiki Formation of the Rewa Basin, India (modified
9 after Bandopadhyay and Ray 2020).

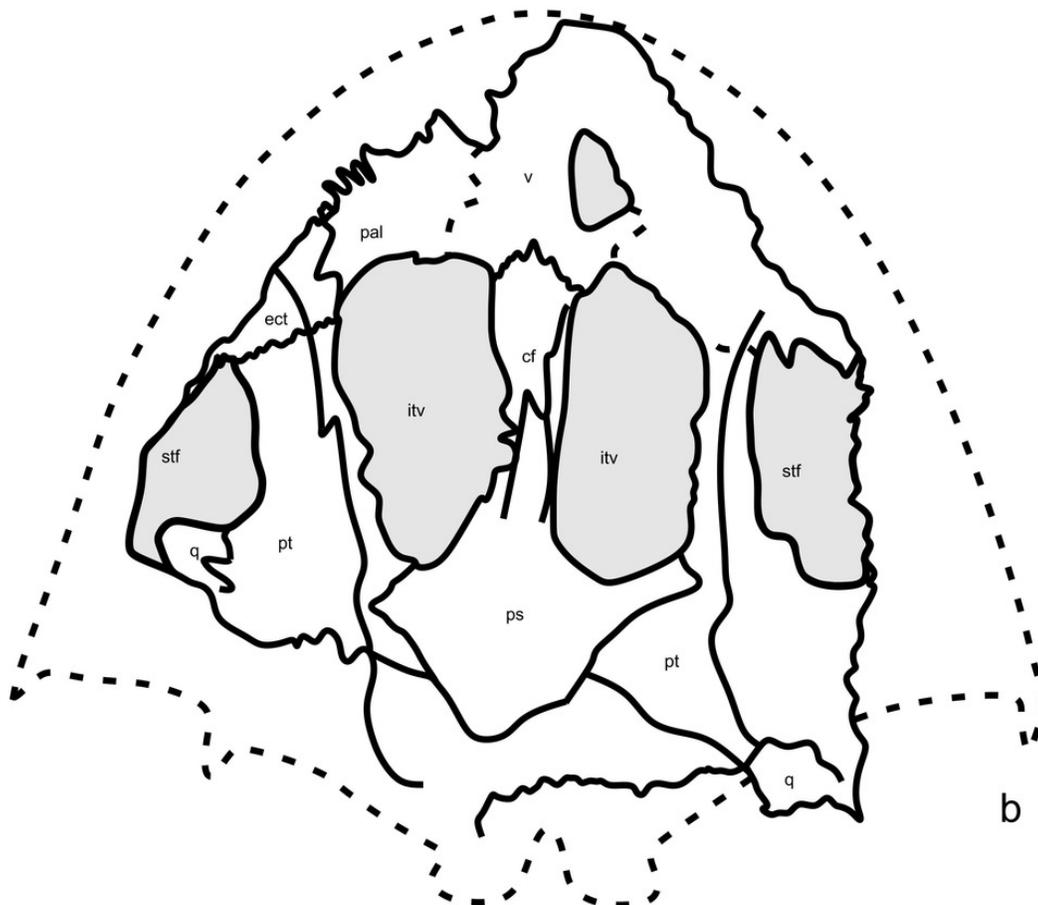

Figure 1

Palatal surface of the skull photograph (RH01/Pal/CHQ/Tiki/15) Kumar and Sharma 2019, recreated with permission from the editor of the Palaeontological Society of India.

a. Shows the field photograph published in Kumar and Sharma (2019). b. is the line drawing showing the disposition of the bones in the palatal surface of the skull published in Kumar and Sharma (2019). The abbreviation stated in the figure are as follows: cf = cultriform process, ect= ectopterygoid, itv = interpterygoid vacuity, pal= palatine, ps = parasphenoid, q = quadrate, stf = subtemporal foramen, v = vomer.

The poorly preserved occiput of ISI A 202 *Compsocerops tikiensis*.

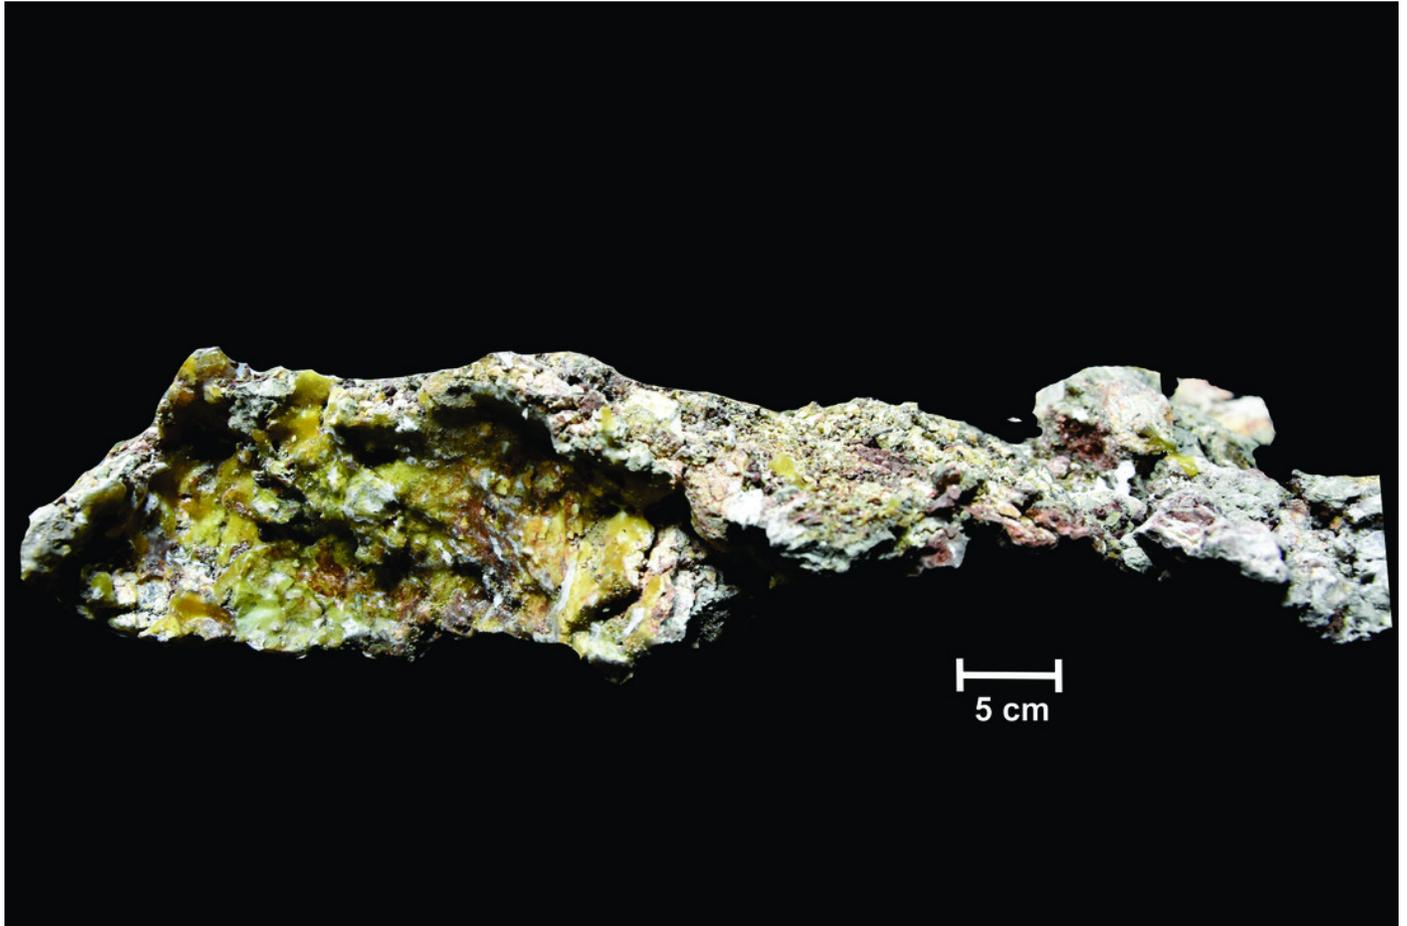

Figure 5

Dorsal view of poorly preserved left clavicle of ISI A 202 *Compsocerops tikiensis*.

Figure 6

Geological Map showing the Tiki Formation, Rewa Basin, India.

Geological map of the Tiki Formation, Rewa Basin, India, modified after Mukherjee et al. (2012). The red dotted line shows the hypothetical faunal boundary.

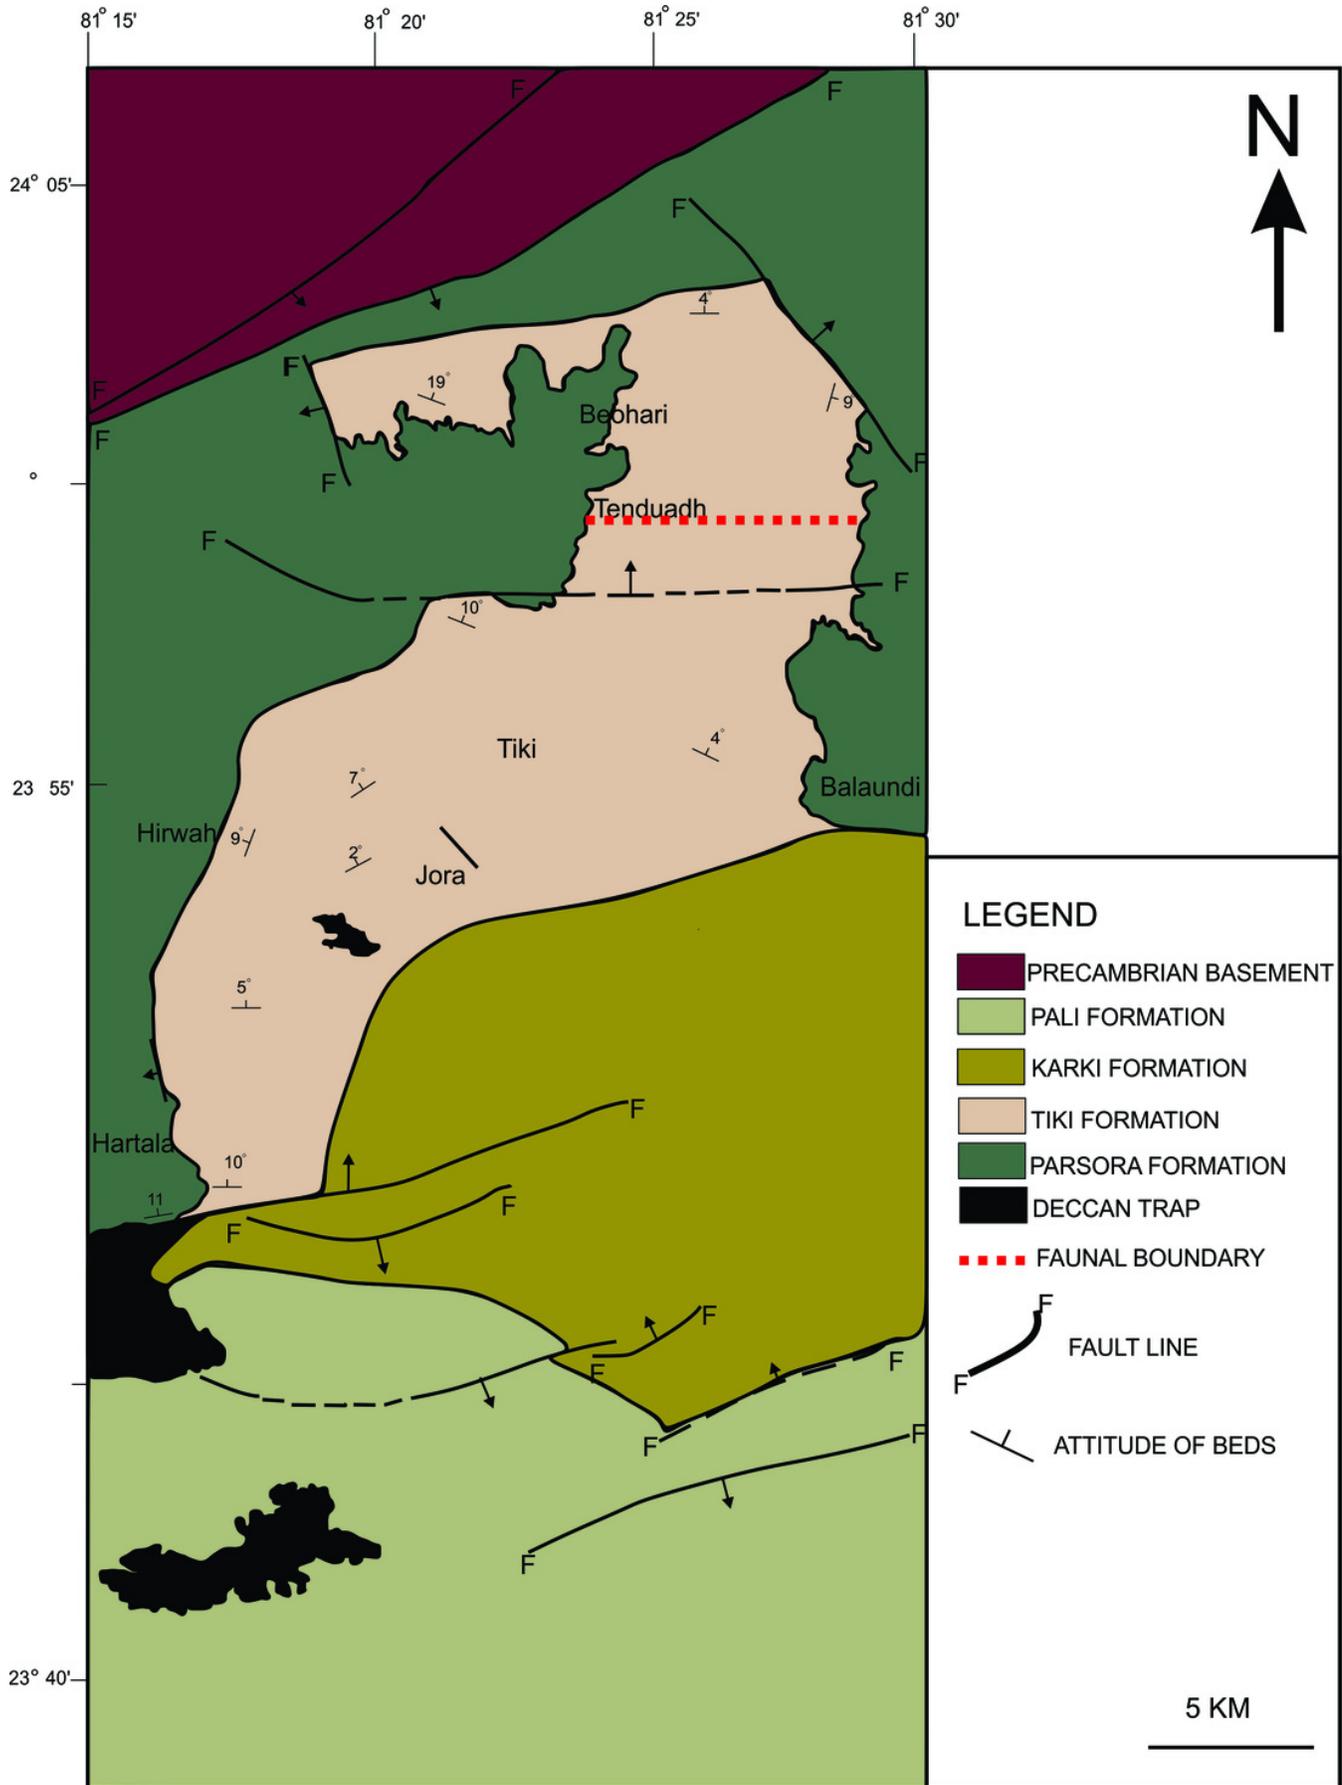

Figure 7

Field photograph showing the exposure of *Compsoceroops tikiensis* embedded in mudstone in the Upper part of the Tiki Formation.

Figure 8

Lithologs of the Tiki Formation.

a. Litholog in the Jora Nala Section in the Lower Tiki Formation. b. Litholog in the Lower part of Tiki Formation modified after Mukherjee et al. (2012). c. Litholog of the Tiki Formation modified after Kumar and Sharma (2019).

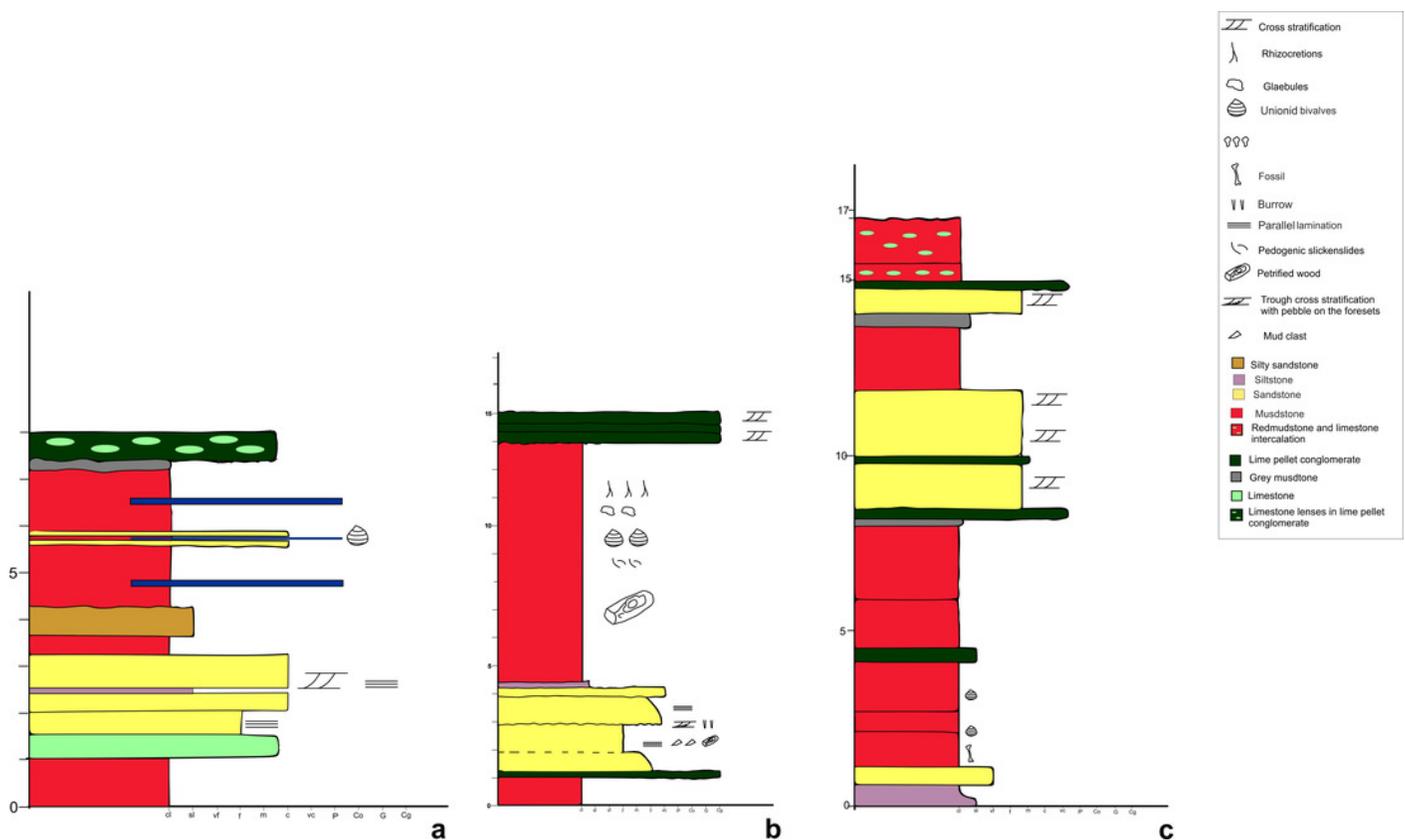

Figure 9

Field photograph of the sand-mud alternation in the Tiki Formation near Tenduadh.

a. Trough cross- bedded sandstone in the Tiki Formation b. Extensive mudstone in the Tiki Formation.

Figure 10

Geological map of the Maleri Formation, Pranhita-Godavari Valley Basin, India

Geological map modified after Kutty and Sengupta (1989), Dasgupta et al. (2017) showing the sand- mud alternations in the Maleri Formation, Pranhita- Godavari Valley Basin, India. The green line represents the faunal boundary that occurred due to the faunal turnover from the Carnian Lower Maleri to the Norian Upper Maleri Formation.

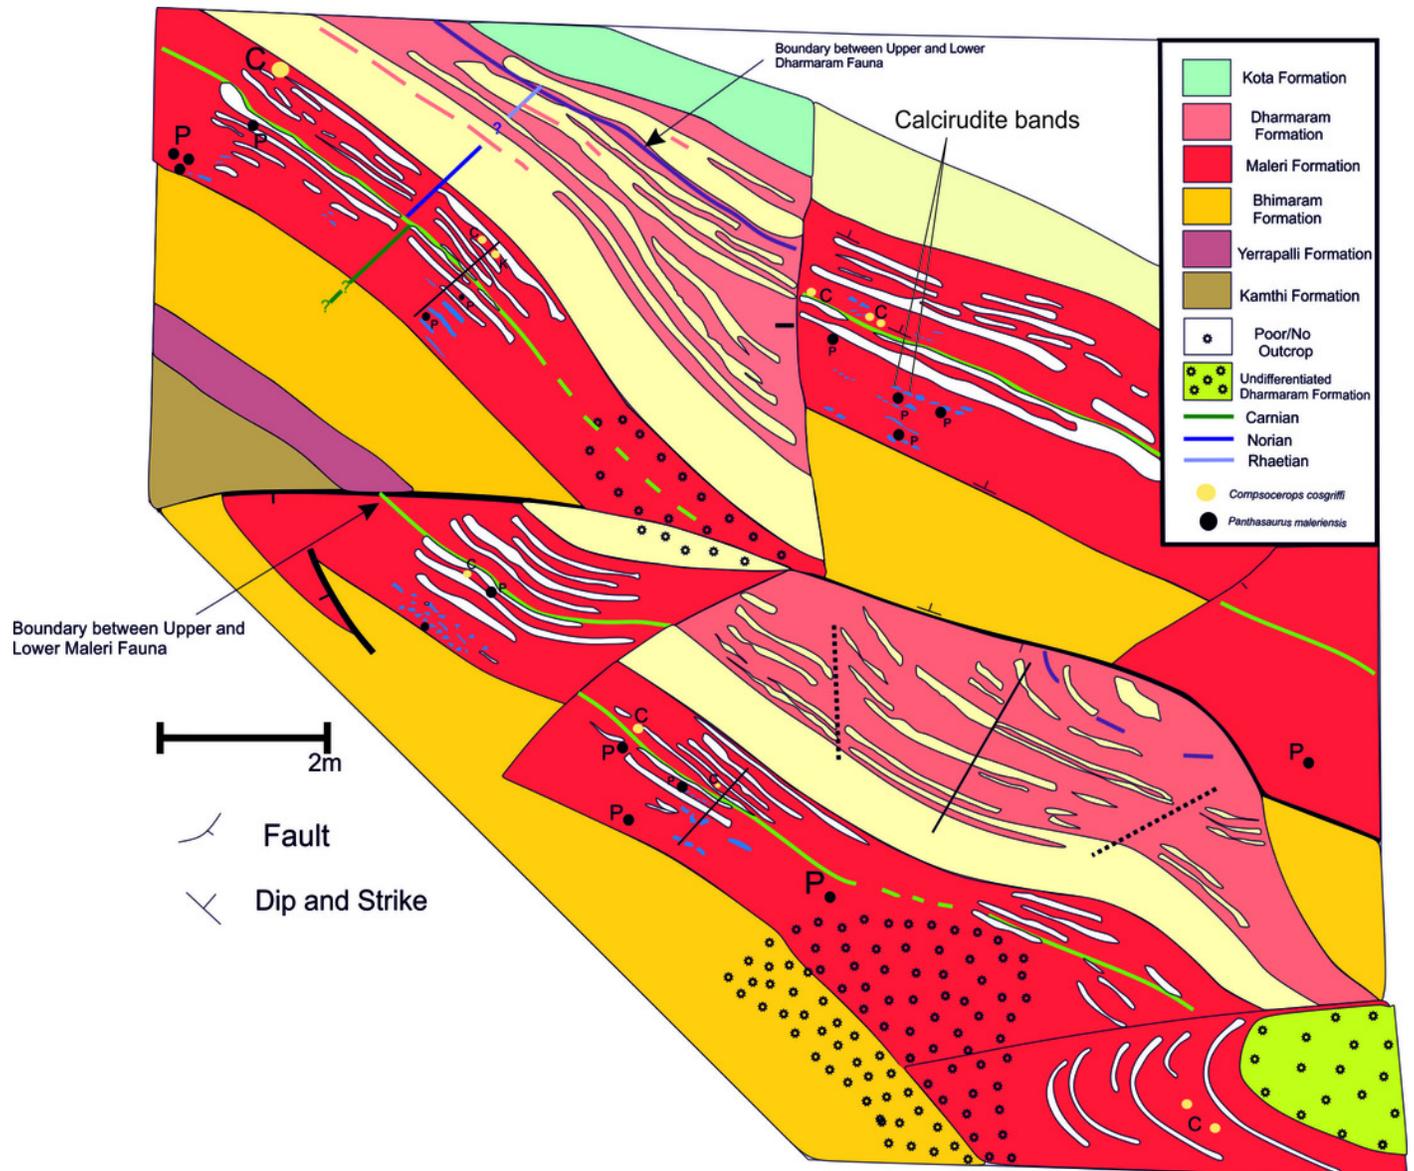

Figure 11

Litholog of the Maleri Formation modified after Kutty and Sengupta (1989).

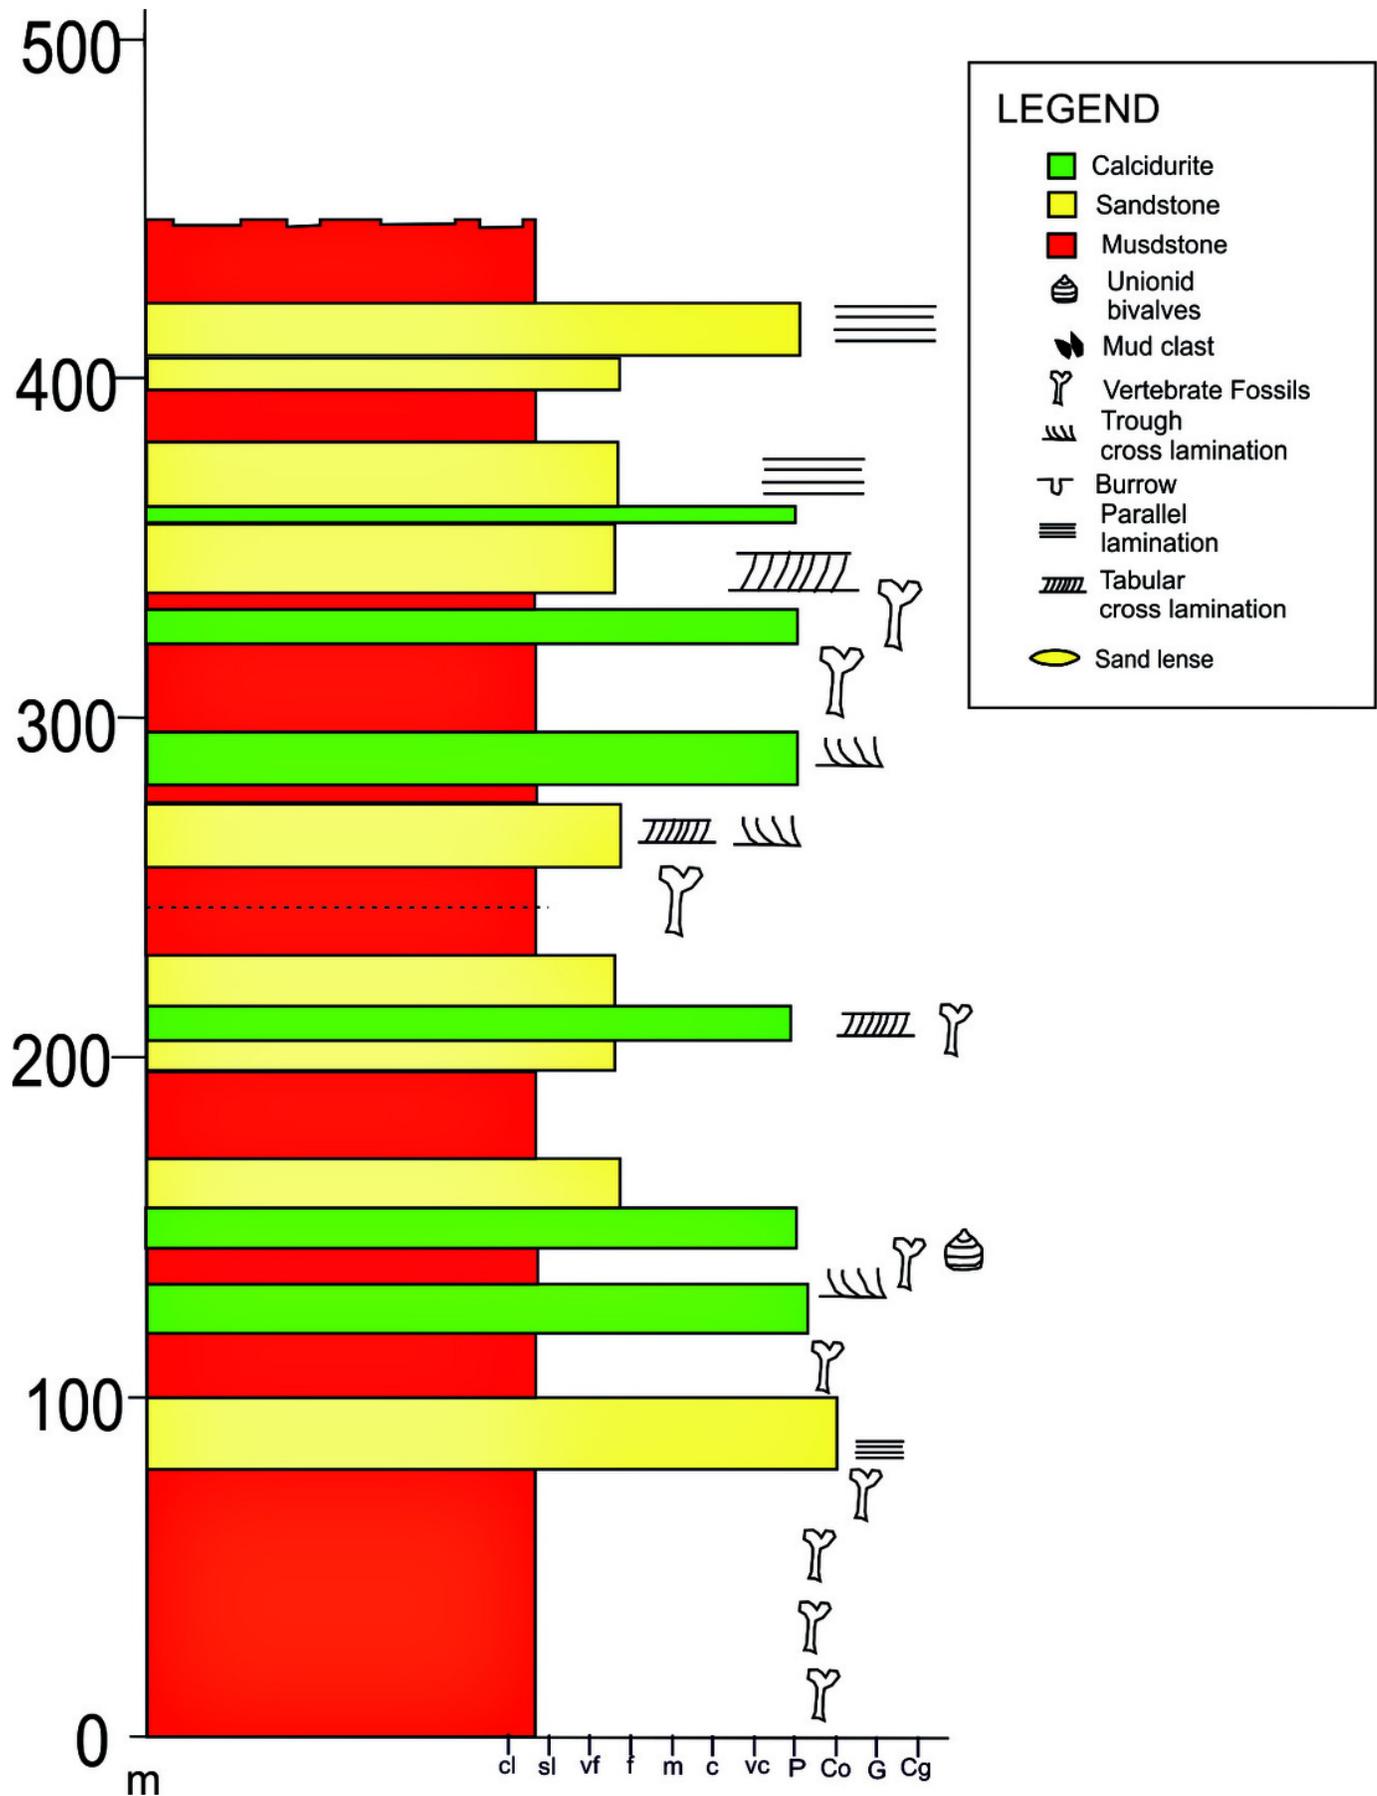

Figure 12

Field photograph showing the abundance of red mudstone in the basal part of the Maleri Formation.
