Background: Knowledge of global clarithromycin (CLA)-resistant rates of *Helicobacter pylori* is crucial for decision of the most appropriate eradication therapies with good clinical outcomes. Therefore, this review and meta-analysis aimed to evaluate the global prevalence of the CLA resistance in *H. pylori* to provide some guidance for selecting the first-line antibiotics. **Method:** A comprehensive search was performed for relevant literature until April 2021 in PubMed, Embase, and Web of Science databases. Freeman-Tukey double arcsine transformation was performed to estimate the weighted pooled prevalence of resistance. **Results:** The meta-analysis included 248 articles. The prevalence of CLA-resistant *H. pylori* was 27.53% (95% CI; 25.41, 29.69). The heterogeneity between reports was significant ($I^2=97.80\%$, $P < 0.01$). The resistance rate increased from 24.28% in 2010-2017 to 32.14% in 2018-2021 ($P < 0.01$). Iran, with 38 articles, has the most report. Nevertheless, Switzerland, Portugal, and Israel had the highest resistance rates (67.16%, 48.11%, and 46.12%, respectively). The heterogeneity between the continents and the antimicrobial susceptibility methods also interpreted standard guidelines and breakpoints was insignificant ($P > 0.05$). **Conclusion:** Overall CLA resistance rate was 27.53%, worldwide. The difference in CLA resistance rate among the included studies can be due to several reasons such as differences in antibiotic prescription rates in various geographic areas, use of different breakpoints or inaccurate criteria in performed studies, and the emergence of multidrug-resistant (MDR) strains.

34 **Abstract**

35 **Background:** Knowledge of global clarithromycin (CLA)-resistant rates of *Helicobacter pylori*
36 is crucial for decision of the most appropriate eradication therapies with good clinical outcomes.
37 Therefore, this review and meta-analysis aimed to evaluate the global prevalence of the CLA
38 resistance in *H. pylori* to provide some guidance for selecting the first-line antibiotics.

39 **Method:** A comprehensive search was performed for relevant literature until April 2021 in
40 PubMed, Embase, and Web of Science databases. Freeman-Tukey double arcsine transformation
41 was performed to estimate the weighted pooled prevalence of resistance.

42 **Results:** The meta-analysis included 248 articles. The prevalence of CLA-resistant *H. pylori* was
43 27.53% (95% CI; 25.41, 29.69). The heterogeneity between reports was significant ($I^2=97.80\%$,
44 $P < 0.01$). The resistance rate increased from 24.28% in 2010-2017 to 32.14% in 2018-2021 ($P <$
45 0.01). Iran, with 38 articles, has the most report. Nevertheless, Switzerland, Portugal, and Israel
46 had the highest resistance rates (67.16%, 48.11%, and 46.12%, respectively). The heterogeneity
47 between the continents and the antimicrobial susceptibility methods also interpreted standard
48 guidelines and breakpoints was insignificant ($P > 0.05$).

49 **Conclusion:** Overall CLA resistance rate was 27.53%, worldwide. The difference in CLA
50 resistance rate among the included studies can be due to several reasons such as differences in
51 antibiotic prescription rates in various geographic areas, use of different breakpoints or
52 inaccurate criteria in performed studies, and the emergence of multidrug-resistant (MDR) strains.

53 **Keywords:** Clarithromycin; meta-analysis; Antibiotic resistance; *Helicobacter pylori*

54

55

56 **Introduction**

57 *Helicobacter pylori* is a successful bacterial pathogen that affects approximately 50% of the
58 population worldwide. In developing countries, 70% - 90% of the people are infected by this
59 bacterium (1, 2). The infection is associated with various gastric diseases including chronic
60 gastritis, uninvestigated and functional dyspepsia, mucosa-associated lymphoid tissue
61 lymphoma, peptic ulcers, and even gastric cancer (3). Due to the high prevalence of the infection
62 and its associated diseases, appropriate and timely treatment is crucial. Today, the standard
63 treatment for *H. pylori* infection is a triple therapy regimen for 14 days that consists of 2
64 antibiotics, clarithromycin (CLA), and metronidazole or amoxicillin, and an acid neutralizer (4).
65 However, treatment is complicated since the bacterium quickly expands resistance against the
66 known effective antibiotics (5). So that the World Health Organization (WHO) has categorized
67 *H. pylori* as one of the 12 most drug-resistant bacteria in the world (6). Unfortunately, the
68 effectiveness of the treatment has decreased to less than 80% worldwide. The treatment failure
69 due to the emergence of resistant strains of *H. pylori* has increased the global prevalence of the
70 disease, followed by inflammatory and neoplastic disorders (2, 7).

71 CLA has emerged as the basis for *H. pylori* treatment in combined therapy because of its small
72 effect on gastric acidity, low minimal inhibitory concentration, and relatively good mucosal
73 diffusion (8, 9). Due to the extensive usage of clarithromycin in some geographical regions, the
74 global prevalence rate of clarithromycin resistance is increasing. (10). In developing countries, in
75 addition to CLA resistance, the frequency of re-infection is another factor contributing to high
76 worldwide infection and subsequent disorders (11). In most European countries and other parts
77 of the world, the prevalence of clarithromycin-resistant *H. pylori* has reached more than 20%.

78 With rare exceptions, it is no longer recommended to include CLA in empirical treatment in
79 regions where primary clarithromycin resistance is 20% (11, 12).

80 Knowledge of global CLA-resistant rates of *H. pylori* is crucial for decisions on the most
81 appropriate eradication therapies with good clinical outcomes. Therefore, the current review and
82 meta-analysis aimed to evaluate the global prevalence of CLA resistance in *H. pylori* to provide
83 some guidance for selecting effective antibiotics.

84 **Methods**

85 **Search strategy**

86 A systematic search was performed for relevant literature with two researchers independently
87 until April 2021 in the online databases including PubMed, Embase, and Web of Science with
88 relevant keywords such as clarithromycin, antibiotic resistance, and *H. pylori* and mesh terms.

89 The search syntax is available in Table 1.

90 **Study selection**

91 All systematic search records from online databases were imported to EndNote (Version 20), and
92 duplicates were removed. Two authors independently performed the title and abstract selection
93 (M-H, S-K); the third author solved any disagreement (V-H-K). Studies were considered eligible
94 for the analysis if they reported data on the prevalence of clarithromycin-resistant *H. pylori*. A
95 restriction on the English language was imposed. In contrast, abstracts, conferences, case reports,
96 case series, reviews, studies with unclear results, and duplicate articles were excluded from
97 proceedings.

98 **Data Extraction**

99 Studies considered appropriate for inclusion based on criteria in our study were evaluated as full
100 text of articles. Two reviewers performed data extraction process independently (M-H, S-K).
101 Discrepancies were discussed and decided by consensus. The primary outcome of interest was
102 the prevalence of clarithromycin-resistant *H. pylori*. The extracted information from each
103 included study were: the first author names, publication year, location, antimicrobial
104 susceptibility test method, breakpoints for antimicrobial susceptibility test results interpretation,
105 sample size, and the number of clarithromycin-resistant *H. pylori*. All extracted data are
106 available in a supplementary file.

107 **Quality Assessment**

108 Two reviewers (S-K and M-H) assessed the quality of studies using the measurement tool
109 Newcastle Ottawa scale (NOS). The disagreement was resolved by the opinion of the third
110 author (M-SH). The three parameters used to evaluate the quality of individual studies were
111 selection, comparability, and exposure/outcome assessments.

112 **Statistical analysis**

113 The sample size of isolates for antimicrobial susceptibility testing (AST) and the number of
114 resistances to each antibiotic were used to estimate a weighted pooled resistance and their 95%
115 confidence intervals. The Inverse of Freeman-Tukey double arcsine transformation was
116 performed by Metaprop command in STATA software (version .17.1). The transformation
117 helped avoid excluding studies from the meta-analysis because of 0 or 100 resistance prevalence.
118 The random-effects model was used to estimate pool proportions (13, 14). The I^2 with a $P \leq 05$
119 was considered a significant heterogeneity. Egger's linear regression test and Begg's test for
120 small-study effects: assessed the small study effect or publication bias (15). The subgroup

121 analyses based on the country, continent, publication year (2017-2010, 2018-2021,) AST ((Disc
122 diffusion, Gradient methods), and breakpoints for interpretation of AST results were investigated
123 as a source of variation.

124 **Results**

125 **Descriptive statistics**

126 In this study 19169 records as results of the systematic search were collected in reference
127 manager software (EndNote version 20), and 8689 duplicated articles were removed).
128 Eventually, this systematic review and meta-analysis included 247 eligible studies. The
129 screening and selection presage were summarized in PRISMA flow chart (Figure 1). Overly
130 20936 *H. pylori* isolates have been investigated in included articles (Supplementary data 1).
131 More than half of the isolates were investigated in Asia (55.10% Isolated). Although most pieces
132 were from Iran (38 articles), the highest number of isolates among the countries was that
133 investigated from China (32,130 Isolates, 36.52% of total isolates). Description data are
134 summarized in Table 2.

135 **Publication bias**

136 The publication bias was significant by the Regression-based Egger test for small-study effects
137 ($P=0.04$), but Begg's test for small-study effects was insignificant ($P=0.09$). The Nonparametric
138 trim-and-fill analysis of publication bias also did not change the effect size. The funnel plot also
139 did not have significant evidence of publication bias (Figure 2A). The sensitivity analysis or one
140 leave-out method also had no significant bias.

141 **Meta-analysis**

142 In 248 included studies, 20936 isolates have been investigated, and 8736 isolates have been
143 reported as resistant. The pooled prevalence of clarithromycin-resistance *H. pylori* was %27.53
144 (%95)CI; 25.41, 29.69(.Heterogeneity between reports was significant ($I^2 = 97.80, p < 0.01$). The
145 heterogeneity between countries was substantial ($p < 0.001$). Switzerland, Portugal, and Israel had
146 the highest resistance rates (67.16%, 48.11%, and 46.12%, respectively), and Senegal, Lithuania,
147 and the Dominican Republic had the lowest resistance prevalence ,%0.93) ,%2.53 and 3.13%,
148 respectively) (Table .(1 The heterogeneity between the continent subgroups was insignificant
149 ($P > 0.05$) (Figure 2B). The heterogeneity between the AST methods subgroup was insignificant
150 ($P > 0.05$) (Figure 2C). The breakpoints for the interpretation AST subgroup were insignificant
151 ($P > 0.05$) (Figure 2D). The clarithromycin-resistant *H. pylori* prevalence increased from 24.28%
152 in 2010-2017 to 32.14% in 2018-2021 years period ($P < 0.01$) (Figure 2E). All statistics are
153 summarized in Table 2. The regression meta-analysis for resistance rate over the publication year
154 had a significant correlation 0.013 (95% CI; 0.01, 0.02) ($P < 0.001$) (Figure 2F).

155 Discussion

156 Over the past years, the treatment of *H. pylori* infections has been performed using the standard
157 triple therapy regimen including CLA, a proton pump inhibitor, with either metronidazole or
158 amoxicillin(16). However, in recent years, it is revealed that some *H. pylori* isolates have
159 developed resistance to CLA(17). Therefore, the efficacy of the standard triple therapy regimen
160 is in decline. In 2017, the World Health Organization (WHO) listed the CLA-resistant *H. pylori*
161 among antibiotic-resistant priority pathogens that need research and development of new
162 antibiotics(18). Globally, surveillance and being aware of the frequency of resistance to
163 antibiotics among pathogens is critical, and obtained results can be helpful in different sections

164 such as the design of screening or follow-up programs, and the development of antimicrobial
165 stewardship programs (19, 20).

166 In the present systematic review and meta-analysis study, we surveyed and analyzed the
167 worldwide prevalence of CLA resistance among *H. pylori* isolates from 2010 to 2021. The
168 awareness of CLA resistance *among different countries of the world* and effective treatment of
169 *H. pylori* infections are the main goal of the current study. The present systematic review and
170 meta-analysis study included 248 eligible studies from 54 different countries. Our analyses
171 revealed that the overall prevalence of clarithromycin-resistance *H. pylori* was 27.53%,
172 worldwide.

173 Resistance to CLA among *H. pylori* is occur in two different levels including 1) a high level of
174 resistance (MIC more than 64 mg l^{-1}) and 2) a low level of resistance ($0.5 \leq \text{MIC} \leq 1 \text{ mg l}^{-1}$)
175 (21). Point mutations, multidrug efflux pump systems, and synergistic effect of mutations in
176 genes *rpl22* (ribosomal protein L22) and *infB* (translation initiation factor IF-2) with 23S rRNA
177 point mutations are the main CLA resistance mechanisms among *H. pylori* isolates (22, 23).
178 Moreover, it is presumed that some outer-membrane proteins have a role in CLA resistance in *H.*
179 *pylori* isolates (22). In the western world and among developed countries, more than 90% of
180 CLA resistance is related to point mutations in the peptidyl transferase region of the V domain of
181 23S rRNA gene (24). The main point mutations related to CLA resistance are A2142G, A2143G
182 (adenine-to-guanine transition at either position 2142 or 2143), A2142C (adenine-to-cytosine
183 transversion at position 2142), A2115G, A2144T, G2141A, G2144T, T2289C, T2717C, and
184 C2694A (16, 22, 23). Moreover, *hp1181* and *hp1184* mutations are associated with CLA
185 resistance(23). Mutation in the 2142 and 2143 positions leads to restricted resistance and
186 different levels of resistance, respectively (25).

187 In the present research, more than half of the included studies were performed in Asia. These
188 results demonstrated that CLA resistance is a main public health issue in most Asia countries.
189 Among studies surveyed CLA resistance rates in 54 different countries, Switzerland (67.16%)
190 and Senegal (0.93%) had the highest and lowest resistance rates, respectively. The high level of
191 CLA resistance can be due to the following reasons: 1) inappropriate prescription and
192 unregulated or widespread use of CLA, and 2) the use of CLA in other infections such as
193 respiratory tract infections or intestinal parasites infections(26). Time trend analyses revealed
194 that the CLA-resistant rates among *H. pylori* isolate increased from 24.28% in 2010-2017 to
195 32.14% in the 2018-2021 years' period. An increase in CLA resistance rates is an alarming
196 finding. In areas where CLA-resistance is more than 15%, it is recommended to perform
197 susceptibility testing before prescribing the standard triple therapy regimen (17, 27).
198 Combination therapy with other drugs such as tinidazole can be helpful in the treatment of *H.*
199 *pylori* infections. It is revealed that CLA combined with tinidazole can reduce the CLA
200 resistance rate, decrease inflammatory reactions, and can effectively eliminate *H. pylori*
201 infections (21). One of the limitation of this study was that we evaluated the CLA resistance rate
202 only and the other antibiotics were not considered.

203 Conclusion

204 Our analysis revealed that CLA resistance rates varied among studies performed in different 54
205 countries. Altogether, results showed that the overall CLA resistance rate is 27.53%, worldwide.
206 The difference in CLA resistance rate among the included studies can be due to several reasons
207 such as differences in antibiotic prescription rates in various geographic areas, use of different
208 MIC breakpoints or inaccurate criteria in performed studies, and the emergence of multidrug-
209 resistant (MDR) strains. We performed a time trend analysis and the results revealed that the

210 clarithromycin-resistance rates in increasing in recent years. Based on our findings, systematic
211 surveillance, and proper monitoring of CLA resistance rates, as well as monitoring the use of
212 CLA in patients, and performing the CLA susceptibility test before prescription may be critical
213 actions for the inhibition and control of *H. pylori* infections.

Table 2(on next page)

Clarithromycin-resistant *Helicobacter pylori* prevalence. 95% Confidence Intervals (CI) were used. $P \leq 0.05$ was considered statistically significant.

High confidence interval (HCl), low confidence interval (LCI), I-squared (I^2), Degrees of freedom (DF).

	No of Article	Clar-resistant, Total isolates	Proportion (LCI, HCl)	Weight	I ² (P)
Overall	248	8736, 87991	27.53 (25.41, 29.69)	100.00	97.80% (P=0.00)
