## ABSTRACT

Asymmetric body traits in bilateral organisms are common and serve a range of different functions. In crustaceans, specifically among brachyuran crabs, heterochely and handedness in some species are known to aid in behavioural responses such as food acquisition, and sexual and territorial displays. However, the heterochely of the intertidal mud crab genus *Scylla* is still poorly understood. This study investigated the cheliped morphometric characteristics of orange mud crab *Scylla olivacea* and the relation of heterochely and handedness to sex. *Scylla olivacea* is heterochelous, with predominant right-handed (70.2%). Three morphometric variables, *i.e.*, propodus length (PL), propodus depth (PD), and propodus width (PW) were significantly larger in the right cheliped and the estimated handedness based on these three variables were consistent with the presence of molariform teeth. The effect of sex had no influence on the occurrence of heterochely or handedness. The frequency of left-handedness increased with size, especially in males. We postulate that handedness reversal, a phenomenon seen in other crab species when the dominant hand is lost, also occurs in *S. olivacea*, thereby resulting in a change in left-handedness frequency. The use of chelipeds by males in mate and territorial defenses might provide an explanation for the higher risk of losing a dominant cheliped and thus, higher left-handedness frequency compared to females. Future behavioural research could shed light on the selective forces that affect the handedness distribution in mud crabs. Knowledge on heterochely and handedness of mud crabs could be useful for future development of less aggressive crab populations by claw reversal and the optimisation of limb autotomy techniques.

## INTRODUCTION

Asymmetries are common among living organisms, and they can be seen in a variety of forms. Asymmetry, either in size or shape, is a pattern that regularly arises in evolutionary processes (Palmer, 1996; Spani et al., 2020). A random minor variation of a morphological trait from perfect bilateral symmetry is an example of what is referred to as fluctuating asymmetry at the population level. Analysis of the degree to which the right and left sides of the organism's bilateral characteristics diverge from one another may be used to estimate the level of body asymmetry that an organism possesses, which can be done by using a population sample (Ottaviano & Scapini, 2010). Often, it results from a difference in how an individual's left and right sides of their body have developed. This state can be interpreted as a deviation from perfect symmetry on the part of an organism or a component of that organism (Van Valen, 1962; Spani et al., 2020). In particular, many decapod crustaceans (Lezcano et al., 2015; Hamasaki & Dan, 2022), including brachyurans, show asymmetry in the shape and size of their chela (Scalici & Gherardi, 2008). The development of heterochely thus results from this disruption of bilateral symmetry (Graham et al., 2010).

The chela, carpus, and merus are the three major cheliped segments of brachyuran crabs. Two primary parts form a chela; the first is a propodus that extends distally and is known as the pollex. The second component is termed as the dactylus, and together they form an appendage that has a pincher-like claw (Claverie & Smith, 2007). Heterochely, in which the two chelae are distinct from one another in terms of size and shape or between the both of them, is a phenomenon that frequently occurs in the Brachyura (Hartnoll, 1982; Silva & Paula, 2008). In most cases, individuals of both sexes exhibit heterochely (Emlen, 2008; Claverie & Smith, 2010). The two chelae are commonly referred to as major and minor chela due to their size disparity. They are also known as the crusher and the cutter based on their functionality in addition to their difference in size (Spani et al., 2020). The major chela can be found on the right side of most crab species, but a small population of left-handed crabs coexists among the species. The occurrence of left-handedness is thought to be due to the reversal of handedness resulting from the major chela being lost from the right side of the crab (Abby-Kalio & Warner, 1989).

*Scylla olivacea* can be found in large numbers throughout most of mangrove forests and in the intertidal zones of the Malaysia's coastal zones. It has been documented in many mangrove regions, including the waters of west Malaysia in the states of Perak (Matang Mangrove Forest Reserve, Taiping) and Terengganu (Setiu), as well as the seas of east Malaysia in the states of Sabah (Kota Merudu), and Sarawak (Lundu) (Waiho, Fazhan & Ikhwanuddin, 2016b; Fazhan, Waiho & Ikhwanuddin, 2017a). In addition to Malaysia, *S. olivacea* is also found in Thailand (Moser et al., 2005), Indonesia (Fujaya et al., 2020), Vietnam (Macintosh, Overton & Thu, 2002), Bangladesh (Rouf et al., 2021), India (Viswanathan & Raffi, 2015), Japan (Ogawa et al., 2011), and western Australia (Keenan, Davie & Mann, 1998). All four species of mud crabs, including *S. olivacea*, are

economically important species and play critical role in sustaining the livelihood of local coastal communities through mud crab fishery and aquaculture.

Most of the research that have been done on chelipeds of mud crabs are related to limb autotomy and regeneration (Quinitio & Estepa, 2011; De la Cruz-Huervana, Quinitio & Corre, 2019; Fujaya et al., 2020; Gong et al., 2022), a process that affects the physiology and behaviour of these animals (Fazhan et al., 2022), and is the primary focus of mud crab aquaculture sector for growth enhancement and optimisation, as well as soft-shell crab production (Fujaya et al., 2020; Rahman et al., 2020). In addition, there is research on the chelae crushing force at multiple gape sizes in *S. olivacea* conducted by Yap, Lin & Todd (2013). However, there are limited knowledge and information regarding the heterochely and handedness of members of the *Scylla* genus, particularly *S. olivacea*. Therefore, in this study, we examined the relationship of heterochely and handedness of the orange mud crab, *S. olivacea*, based on selected cheliped morphometric characteristics. The potential biological functions of heterochely and handedness of *S. olivacea* were further discussed. Knowledge of the presence of heterochely and handedness in *S. olivacea* serves as an essential foundation for future research on limb autotomy and regeneration of mud crabs.

## MATERIALS & METHODS

Mud crabs were sampled from Matang Mangrove Forest Reserve, Perak, Malaysia (4°45'N 100°37'E). Standard crab pots with trash fish as baits were deployed during low tide and retrieved on the subsequent low tide. Mud crab fishery is permitted at Matang Mangrove Forest Reserve and supports the livelihood of local communities; thus, no specific license is needed for the capture of mud crabs. Upon capture, mud crabs were identified at the species level based on the morphological characters provided by Keenan, Davie & Mann (1998) and Fazhan et al. (2020). *Scylla olivacea* has distinct orange or red through brown to black coloured chelipeds, rounded frontal lobe spines, reduced outer carpus spines, lack of inner carpus spines, and reduced propodus spines. After species identification, crabs were then sexed according to their abdomen shape and characters; males possess triangular-shaped abdomens, whereas females have darkened globular abdomens in mature individuals and slightly rounded abdomens in immature individuals (Ikhwanuddin et al., 2011; Fazhan et al., 2021). Due to the lack of clear and objective morphological character to discern between immature and mature males, previously determined size at sexual maturity (carapace width, CW<sub>50</sub>) of 87 mm CW for *S. olivacea* from the same population was used in this study (Waiho, Fazhan & Ikhwanuddin, 2016b). In addition, the abdomen looseness of each male was also checked; males were considered as mature if the abdomen was not locked to the sternum when probed using a dissecting needle, whereas only the telson can be flipped open in immature males (Waiho et al., 2016a). Only crabs with no physical signs of abnormalities or disease were used. Crabs with missing one or both chelipeds were measured but not included in heterochely analysis. After data collection, all crabs were either released live to the mangrove, returned to local fishers, or used in other mud crab-related studies.

Morphometric measurements of the carapace, including CW—the distance between the tips of the 9th anterolateral spine, internal CW (ICW)—the distance between the groove

of the 8th and 9th anterolateral spine, carapace length (CL)—the distance between the middle of the rostrum (between the eye socket) and the most posterior part of the carapace, and that of both chelipeds, including cheliped dactyl length (DL), propodus length (PL), propodus width (PW), propodus depth (PD), and merus length (ML) were measured to the nearest 0.01 mm using digital vernier caliper (Fazhan *et al.*, 2020). In addition, body weight (BW) was weighed to the nearest 0.1 g using a standard digital weighing scale. Tooth types, either molariform or serratiform type, of both chelipeds of males ( $n = 15$ ) and females ( $n = 15$ ) were also analysed, and the large molar tooth on each cheliped was measured to the nearest 0.01 mm. All mean values are expressed using standard deviation unless stated otherwise.

Data analysis was performed in SPSS Statistic ver. 25. CW was chosen as the reference baseline parameter (independent variable) for regression analyses, as it is a commonly used size measurement standard in portunid crabs, including mud crabs, due to the ease of measurement and the lack of abrupt changes while reaching morphometric maturity (Parvizi *et al.*, 2017; Waiho *et al.*, 2017). Data were checked for normality using the Shapiro–Wilk test. Data of cheliped dimensions, *i.e.*, DL, PL, ML, PD and PW, were not normally distributed ( $P < 0.05$ ), except for DL of left cheliped ( $P = 0.138$ ). As the paired-samples *t*-test is robust to violations of normality (Wiedermann & Von Eye, 2013), paired comparisons of left and right cheliped dimensions were conducted, with any violations of normality being noted. The Chi-square test of independence was conducted to determine the relationship between handedness (left or right) and sex, maturation status, and body size (CW size class); the assumptions of the chi-square test were met, and all expected cell frequencies were above five. Binomial logistic regression was conducted using handedness as the dependent variable and sex, maturation status, CW, ICW, and CL as the predictor variables to predict the probability of *S. olivacea* being left- or right-handed based on the independent variables. Regression analyses were conducted on log-transformed variables; cheliped variables based on handedness and sex were considered as dependent variables, whereas CW was regarded as the independent variable. Owing to the lack of significant difference in handedness according to maturation status, this variable was collapsed in the subsequent regression analysis. However, we maintained sex as an important category throughout regression analysis to aid in understanding the handedness pattern in major and minor chelipeds of *S. olivacea*. Statistical significance level was set at  $P = 0.05$ .

## RESULTS

A total of 151 individuals were obtained, and all had both chelipeds intact (Table 1). Only two mature males were missing their left cheliped dactylus (Table S1). *Scylla olivacea* is heterochelous, in which PL, PD, and PW of right cheliped were  $1.28 \times$ ,  $1.39 \times$ , and  $0.74 \times$  larger than that of left cheliped (PL:  $t(150) = 3.827$ ,  $P < 0.001$ ; PD:  $t(150) = 4.63$ ,  $P < 0.001$ ; PW:  $t(150) = 3.744$ ,  $P < 0.001$ ). However, DL and ML were not significantly difference between left and right chelipeds (DL:  $t(148) = 0.343$ ,  $P = 0.732$ ; ML:  $t(150) = 1.442$ ,  $P = 0.151$ ). In addition, it was observed that crabs, in general, had a larger tooth on the major cheliped, and the first major tooth on the right cheliped was 1.18 times larger

than that on the left cheliped ( $t(18) = 2.314$ ,  $P = 0.033$ ; the assumption of normality was not violated, as assessed by Shapiro–Wilk’s test,  $P = 0.141$  for right tooth and  $P = 0.225$  for left tooth). Manual handedness assessment by comparing the PL, PD and PW of both chelipeds revealed that handedness based on these three cheliped morphometric characters was in sync with the handedness estimated *via* the presence of large molariform cheliped on the major cheliped, whereas in comparison, minor cheliped has angular and serrate teeth (Fig. 1; Table S1). In addition, major cheliped, either left or right, showed consistent superiority in size in all three morphometric characters (PL, PD, and PW), except for four right-handed individuals with larger left PW and one left-handed individual with larger right PW. No individual was found to have both large chelipeds.

Overall, 70.2% of the measured individuals were right-handed (106 out of 151 individuals). When divided according to size class, left-handed individuals were concentrated between 76–115 mm CW, and the highest percentage of left-handed crabs (37.5%) was found between the size of 91 to 95 mm CW (Fig. 2). There was no significant association between handedness and sex ( $\chi^2(1) = 0.023$ ,  $P = 0.880$ , Cramer’s  $V = 0.012$ ), between handedness and maturation status ( $\chi^2(1) = 0.0004$ ,  $P = 0.983$ , Cramer’s  $V = 0.002$ ), and between handedness and CW size class ( $\chi^2(10) = 7.662$ ,  $P = 0.662$ , Cramer’s  $V = 0.225$ ) of *S. olivacea*. Additionally, the logistic regression model (Hosmer and Lemeshow test;  $\chi^2(8) = 3.303$ ,  $P = 0.914$ ) with a correct classification of 99.1% indicated that all five predictor variables, *i.e.*, sex, maturation status, CW, ICW, and CL, failed to predict handedness status in *S. olivacea* (Table 2).

All cheliped variables of right-handed individuals exhibited a stronger relationship with CW compared to that of left-handed individuals, as implied by their higher coefficient of determination ( $R^2$ ) values, except for the RPW of right-handed females (Table 3). The size of PL, PD, and PW on the major cheliped, regardless of if the major cheliped is left or right cheliped, was always larger than the corresponding variables on the minor cheliped (Fig. 3). Additionally, the size of PL, PD, and PW on both major and minor chelipeds of right-handed individuals was larger than that of left-handed individuals, and this pattern became clearer with increasing body size (CW). Notably, the PL of males and PD of females showed an inverse relationship (the sizes of PL or PD on major and minor chelipeds of left-handed crabs were larger than that of right-handed crabs) when CW was small but reverted to right-handed biased size difference as the CW increases.

## DISCUSSION

Most species of brachyuran crabs, including those of the family Portunidae, are known to be heterochelous (Abby-Kalio & Warner, 1989; Haefner Jr, 2000; Akin-Oriola, Anetekhai & Olowonirejuaro, 2005; Zainal, 2017). The understanding of heterochely in a species would aid in deciphering the potential function of biased cheliped sizes and provide added information to its life history. Although not as prominent as possessing one large cheliped as in some crab species such as fiddler crabs *Uca* spp. (Yamaguchi & Henmi, 2001; Martins & Masunari, 2013), morphometric comparison of cheliped variables suggests the presence of heterochely in mud crab *S. olivacea*, with a higher percentage of individuals being right-handed. The right-handed biasness among brachyuran crabs is common,

**Notes.** BW, body weight; CW, carapace width; ICW, internal carapace width; CL, carapace length; RDL, right dactyl length; RPL, right propodus length; RML, right merus length; RPD, right propodus depth; RPW, right propodus width; LDL, left dactyl length; LPL, left propodus length; LML, left merus length; LPD, left propodus depth; LPW, left propodus width.

especially in predatory brachyuran species, in which the presence of right-handed major cheliped would facilitate easier handling of molluscan preys that are often asymmetric, dextrogerous, and exhibit right-handed shell coiling (Goés & Fransozo, 1998; Mariappan, Balasundaram & Schmitz, 2000; Dietl & Hendricks, 2006). The dominant right-handed individuals observed in *S. olivacea* thus could be driven by its natural feeding habits (Seed & Hughes, 1995) as hard-shelled bivalves are among the primary consumed food of mud crabs of the genus *Scylla* (Viswanathan & Raffi, 2015; Ghazali et al., 2017; Fazhan et al., 2022). Similarly, in other portunids that exhibit right-handedness, such as Gazami crabs *Portunus trituberculatus*, Masunari et al. (2020) noticed that *P. trituberculatus* exclusively used their major (right) cheliped to crack open shells. Based on handedness development during the megalopa stage of *P. trituberculatus*, Masunari et al. (2015) postulate that the earliest durophagous crabs favoured the selection of right-handedness, and this character preference subsequently succeeded to extant species. Similarly, right-handedness in the xanthid crab *Eriphia smithii* conferred greater attack success on the dextral snail *Planaxis sulcatus* (Shigemiya, 2003). Future studies on the handedness characteristics of *S. olivacea* during early development stages will be helpful in validating the right-handed inheritability observed in other portunid species.

The presence of a large-sized molariform tooth on the major cheliped (or also known as the crusher) in *S. olivacea* might also be an evolutionary adaptation to facilitate better grasping and provide added mechanical force (Freire, Sampedro & González-Gurriarán, 1996; Mariappan, Balasundaram & Schmitz, 2000) during feeding of crustaceans and molluscs of various shapes and sizes. Similar presence of a large tooth on the major

**Figure 1** (A–D) Examples of heterochely and the presence of large molariform teeth on major cheliped. The measurement points for molariform teeth are represented by dotted lines as in (A). (A) Left molariform = 4.43 mm, right molariform = 5.48 mm. (B) Left molariform = 4.76 mm, right molariform = 5.56 mm. (C) Left molariform = 3.61 mm, right molariform = 5.93 mm. (D) Left molariform = 4.55 mm, right molariform = 3.14 mm.

cheliped is common in other heterochelous crab species and is often used as an indicator for handedness (Yamaguchi & Tokunaga, 1995; Goés & Fransozo, 1998). *S. olivacea* with two major or minor chelipeds was not observed in this study, as all crabs showed the presence of major molariform teeth in one of its chelipeds. Similar absence of individuals possessing two major chelipeds was reported in other portunids, including *Portunus pelagicus* (Zainal, 2017), *Carcinus maenas* (Abby-Kalio & Warner, 1989), *Liocarcinus deputator* and *Macropipus tuberculatus* (Abello, Pertierra & Reid, 1990). In comparison, individuals with two small chelipeds or two large chelipeds have been reported in brachyurans of other families, such as in fiddler crab *Tubuca arcuata* (Yamaguchi & Henmi, 2001; Vale et al.,

2015). Since cheliped morphology, including the presence of molariform teeth, influence the generation of force and link with hardness of diet (Schenk & Wainwright, 2001), behavioural and selection studies on various diet types and cheliped shape and size of *S. olivacea* are warranted in the near future.

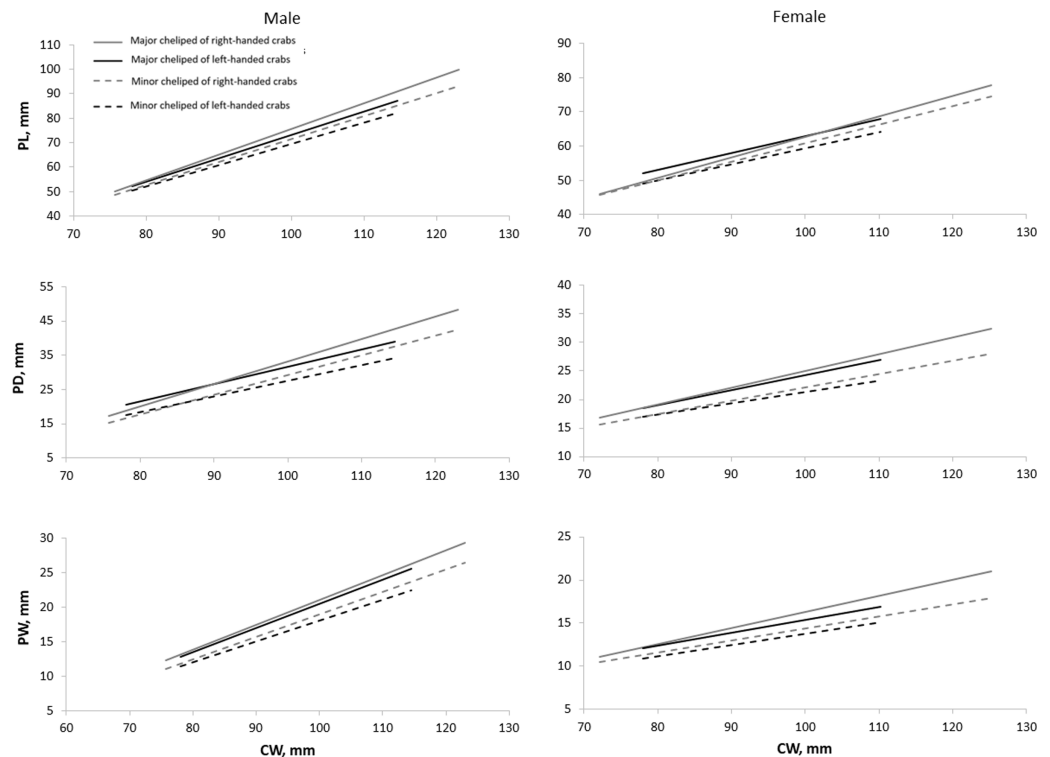

The 70.2% right-handed *S. olivacea* found in this study fall within the range of other right-handed crab species as well. For example, a range of 78.0% to 82.5% right-handed individuals was reported in *C. sapidus* (Hamilton, Nishimoto & Halusky, 1976; Smith, 1990), 75.3% right-handedness in *Potamon potamios* (Scalici & Gherardi, 2008), 83.5% right-handed crabs in *C. ornatus* (Haefner Jr, 1990), 80.4% right-handedness in *Eriphia gonagra* (Goés & Fransozo, 1998), and 79% right-handed individuals in *C. maenas* (Abby-Kalio & Warner, 1989). Right-handed individuals were found to be dominant in all size classes of *S. olivacea*, with 100% right-handed individuals being observed in the smallest and largest size classes. In other crabs and shrimp species, the reversal of handedness is well documented, such as in crabs *Menippe mercenaria* (Simonson, 1985), *P. trituberculatus* (Masunari et al., 2020), *Callinectes sapidus*, *C. maenas*, *Callinectes ornatus*, *Monomia argentata* (Yamaguchi

& Tokunaga, 1995), and snapping shrimp *Alpheus angulosus* (Cooney, Korey & Hughes, 2017). Left-handed crabs risen from the loss of the right major cheliped might not attain the same shape and crushing force as the original right major cheliped (Masunari et al., 2015). However, there are species, such as lithodid crab *Lopholithodes foraminatus* (Duguid, 2010), that will not reverse the direction of cheliped asymmetry despite experiencing limb loss of the major cheliped. Although the event of handedness reversal is yet to be documented in *S. olivacea*, the presence of left-handed individuals in a lesser percentage and only in the sub-adult size classes might suggest that they were originally right-handed crabs and experienced handedness transition due to the chela loss. Mud crabs of the genus *Scylla* are known for their aggressiveness and cannibalistic nature (Fujaya et al., 2020; Kawamura et al., 2020). Sub-adults might have a higher chance of losing their major cheliped during fighting with other larger-sized crabs over food, territory, or mate (Fazhan et al., 2017b) and thus resulting in the occurrence of left-handed individuals at these size classes. In

**Figure 3** Relationship of carapace width (CW) and cheliped characters (i.e., propodus length (PL), propodus depth (PD), and propodus width (PW)) on major and minor chelipeds of *Scylla olivacea*.  
Full-size [DOI: 10.7717/peerj.15143/fig-3](https://doi.org/10.7717/peerj.15143/fig-3)

comparison, some species (e.g., *Charybdis bimaculata*) are suggested to innately develop left-handedness based on the similar percentage of left-handedness across size groups (Yamaguchi & Tokunaga, 1995). The increase of left-handed individuals as size increases in *S. olivacea* is also evident in other portunid species (Hamilton, Nishimoto & Halusky, 1976; Haefner Jr, 1990; Norman & Jones, 1991; Smith & Hines, 1991; Yamaguchi & Tokunaga, 1995).

The presence of heterochely in both sexes and the non-association between handedness and sex, as observed in males and females of *S. olivacea*, is commonly observed in other crab species as well (Abello, Pertierra & Reid, 1990; Goés & Fransozo, 1998; Scalici & Gherardi, 2008). We postulate that the similar heterochely phenomenon in both sexes of *S. olivacea* might be related to the shared biological functions of having a major cheliped, such as in food acquisition (Scalici & Gherardi, 2008) and territorial guarding (Mariappan, Balasundaram & Schmitz, 2000). Interestingly, major and minor chelipeds of right-handed individuals were larger compared to that of left-handed individuals. One of the possible explanations is that handedness reversal in crabs that have lost their right major cheliped might take up to several moults (Hamilton, Nishimoto & Halusky, 1976; Simonson, 1985). Left-handedness in a predominantly right-handed population has been related to lower aggressiveness (less likely to initiate a fight, engaged in less fights, and less likely to win a fight) in crabs such as *Uca* spp. (Backwell et al., 2007). Handedness reversal is still

undocumented in *Scylla* spp., and its validation in the future experiment could provide the basis for the optimisation of mud crab culture *via* the development of a less aggressive left-handed dominant mud crab population.

## CONCLUSIONS

In conclusion, the knowledge that *S. olivacea* exhibits heterochely and is predominantly right-handed provides a basis for understanding its ecological functions. In addition to traditional morphometric indices to discern heterochely, future studies could look into new indices –heterometry (ratio between the ‘size index’ of chelipeds) and heteromorphy (numerical quantification of shape differences between chelipeds) ([Spani et al., 2020](#)), and correlate them with ecological indices. As we show that heterochely and handedness occur in mud crabs, future aquaculture practices might benefit by exploring the potential lesser impact of autotomy of its minor instead of major chelipeds during moult induction practices during soft-shell crab production ([Waiho et al., 2021](#)).

## ACKNOWLEDGEMENTS

We thank Institute of Tropical Aquaculture and Fisheries, Universiti Malaysia Terengganu for providing working space and aiding in crab provision.

## ADDITIONAL INFORMATION AND DECLARATIONS

### Funding

This study was supported by the Ministry of Higher Education Malaysia, under the Higher Centre of Excellence (HiCoE) program, Malaysia accredited to the Institute of Tropical Aquaculture and Fisheries, Universiti Malaysia Terengganu (Vot No. 63933 & 56042). Khor Waiho was supported by a Visiting Researcher Program (Manajemen Talenta BRIN 2022) from the National Research and Innovation Agency, Indonesia and Khor Waiho and Hanafiah Fazhan received adjunct Academic Fellow positions from USM. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

### Grant Disclosures

The following grant information was disclosed by the authors:

Ministry of Higher Education Malaysia.

Institute of Tropical Aquaculture and Fisheries, Universiti Malaysia Terengganu.

National Research and Innovation Agency, Indonesia.

USM.

### Competing Interests

Khor Waiho is an Academic Editor for PeerJ.

## Author Contributions

- Rusydi Rozaimi performed the experiments, analyzed the data, authored or reviewed drafts of the article, and approved the final draft.
- Alexander Chong Shu-Chien performed the experiments, analyzed the data, prepared figures and/or tables, and approved the final draft.
- Youji Wang analyzed the data, authored or reviewed drafts of the article, and approved the final draft.
- Sutikno Sutikno analyzed the data, prepared figures and/or tables, and approved the final draft.
- Mhd Ikhwanuddin analyzed the data, prepared figures and/or tables, and approved the final draft.
- Xi Shi analyzed the data, prepared figures and/or tables, and approved the final draft.
- Ghazali Azmie performed the experiments, prepared figures and/or tables, and approved the final draft.
- Hanafiah Fazhan conceived and designed the experiments, performed the experiments, authored or reviewed drafts of the article, and approved the final draft.
- Khor Waiho conceived and designed the experiments, performed the experiments, authored or reviewed drafts of the article, and approved the final draft.

## Data Availability

The following information was supplied regarding data availability:

The raw measurements are available in the [Supplementary File](#).

## Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.15143#supplemental-information>.
