Abstract

Melanoma is a common skin tumor in high mortality, especially in Europe, North America and Oceania. Immunosuppressants such as PD-1 have been proved to be effective in the treatment of malignant melanoma. However, 60% of patients have no immune response. Sema4D is called CD100 and is distributed to T cells and other types of cancer. Sema4D and its receptor, Plexin-B1, plays crucial roles in the immune regulation, angiogenesis, and tumor progression, while Sema4D/Plexin-B1 in melanoma with anti-PD-1 resistance are still poorly understood. To verify the roles of Sema4D/Plexin-B1 in melanoma with anti-PD-1 resistance and the mechanism of Sema4D involvement in nivolumab resistance was related to PI3K/AKT pathway, we first detected the expression differences of Sema4D and Plexin-B1 in drug-resistant cell lines(B16-F10R) and sensitive cell lines(B16-F10), then B16-F10R cells were divided into Sema4D-shRNA group and Sema4D-NC group, co-cultured with TIL at a 1:5 ratio and nivolumab 50 ng/mL for 24 hours, cell viability, cell apoptosis, cell invasion, cell migration and PI3K/AKT expression were detected. In vitro, 12 Balb/c mice with 12-week-old and half male and female were divided into Sema4D-shRNA group and Sema4D-NC group which intradermal injected with B16-F10R-Sema4D-shRNA cells and B16-F10R-Sema4D-NC cells respectively, then

intraperitoneally injected nivolumab 10 mg/kg once at day 1, tumor volumes were measured on 1, 3, 6, 9, 12, 15, 18 days and tumor weight was measured at days 18. The results showed that the expression of Sema4D, Plexin-B1 was significantly overexpressed in B16-F10R anti-PD-1 resistance cell. Cell viability, cell invasion and migration are significantly decreased, while the apoptosis was increased by Sema4D knockdown synergizes with anti-PD-1 treatment. Moreover, the growth of tumors on the body surface of mice was also inhibited. Mechanistically, bioinformatics analysis revealed that Sema4D is involved in the PI3K/AKT signaling pathway. Downregulation of p-PI3K/PI3K and p-AKT/AKT expression were observed in Sema4D knockdown. Therefore, PD-1 inhibitor resistance is related to Sema4D/Plexin-B1 and Sema4D deficiency can overcome resistance to anti-PD-1 therapy via PI3K/AKT signaling pathway.

Keywords: Sema4D, Melanoma, Nivolumab, PI3K/AKT, PD-1 inhibitor resistance.

INTRODUCTION

Melanoma, which is prevalent in Europe and North America, has been on the rise in recent years (Rodriguez-Cerdeira et al., 2017). Melanoma is the most aggressive and fatal skin cancer, which can easily metastasize to the whole body through lymph and blood vessels. Melanoma has high tolerance to treatment and poor prognosis. If the tumor metastasizes to distant and visceral organs, the 5-year survival rate is only 15-20% (Huang and Zappasodi, 2022, Eggermont et al., 2014). The current treatment for melanoma includes surgery, chemoradiotherapy, targeted therapy and immunotherapy (Miller and Mihm, 2006). Because cutaneous melanoma is often associated with UV exposure and elevated tumor mutational load, melanoma is one of the most immunogenic of all cancer types and one of the most effective for immunotherapy (Melixetian et al., 2022).

Immune checkpoints include programmed cell death protein-1 (PD-1) and programmed death-ligand 1 (PD-L1) play important role in immunotherapy, PD-L1 is distributed in tumor cell and PD-1 is generally distributed in T-cells, when PD-L1 bind to its receptor PD-1, triggers inhibitory signaling to attenuate T cell activity (Sun et al., 2018). PD-1 or PD-L1 inhibitors such as nivolumab and pembrolizumab can prevent the binding of PD-1 to PD-L1, thus restoring T cell activity and killing tumors (Larkin et al., 2015, Ribas et al., 2015, Weber et al., 2015). Clinical evidence indicated that there are only 30-40% of patients receiving PD-1 or PD-L1 inhibitors could achieve a complete response (Hugo et al., 2016). Furthermore, there are a growing subset of responders acquired resistance within two years after treatment induction in melanoma (Robert et al., 2015b, Robert et al., 2015a). Therefore, it is urgent to develop new biomarkers with predictive value in the treatment of PD-1 inhibitor.

Semaphorins has become a key factor in regulating tumor growth and metastasis. Especially in the tumor microenvironment, the disturbance between different cell types can control the development and progression of cancer (Valentini et al., 2021, Lontos et al., 2018). Semaphorin 4D (Sema4D) is a member of the Semaphorins, which has immunoregulatory activity, platelet inactivation, angiogenesis stimulation and bone formation regulation (Lontos et al., 2018). Sema4D increased in most tumors, such as prostate, colon, breast, melanoma, head, and neck carcinomas (Liu et al., 2015). As a ligand of Sema4D, Plexin-B1 plays important roles in tumor

cell proliferation, survival, and migration via Sema4D/Plexin-B1 signal pathway (Ch'ng and Kumanogoh, 2010).

The phosphatidylinositol 3-kinase/protein kinase B (PI3K/AKT) pathway is involved in the occurrence and development of melanoma, Long noncoding RNA OR3A4, GRB2 and Hey1 can promote melanoma migration and invasion via this signaling pathway (Shayan et al., 2017, Wu et al., 2020). When PI3K combines with GRB2, it is phosphorylated, recruited to the cell membrane and activated, then AKT phosphorylated and acts on its target genes to regulate a variety of cellular processes (Yu et al., 2006).

However, in melanoma, roles of Sema4D in the anti-PD-1 tolerance is unclear. In this study, we use a combination of molecular biology techniques and bioinformatics to study the roles of Sema4D in anti-PD-1 resistance melanoma. We provide the evidence for the first time that Sema4D/Plexin-B1 is involved in anti-PD-1 resistance of melanoma. Moreover, Sema4D deficiency can overcome resistance to anti-PD-1 therapy, the mechanism is related to PI3K/AKT signaling pathway.

MATERIALS AND METHODS

Cell culture and B16-F10 resistance cell line establishment

293T cells, B16-F10 were purchased by Nanjing Cobioer Biotechnology Co., LTD (Nanjing, China), cultured at 37°C in 5% CO₂ in RPMI-1640 (Life Technologies, Invitrogen, Canada) with 10% FBS (Gibco, USA). The combination of high dose shock and gradually increasing dose was applied to establish the cell lines insensitive to nivolumab (anti-PD-1). The B16-F10 cell line in the logarithmic growth phase were cultured with nivolumab (AbMole Bioscience Inc., shanghai, China) 10 ng/mL and TIL at a 1:5 ratio. After 24 hours, the solution was changed, and dead cells were discarded. The remaining cells were then cultured with RPMI-1640 without nivolumab, when the remaining cells have stabilized, then cultured with nivolumab 25 ng/ml and repeat these steps until the cells could grow continuously and stably in the medium with nivolumab 50 ng/mL, and then cultured drug-free for 1 month, B16-F10 resistance cell line (B16-F10R) were obtained. B16-F10R also needs with nivolumab 5 ng/mL to maintain the resistance (Maeda et al., 1991).

Tumor Infiltrating Lymphocyte (TIL)

The tumors were removed from the Balb/c mice, about 2-3 cubic millimeters in size, and cultured with 2 mL complete medium in 24 well plates. The complete medium included 6000 IU/mL IL-2 which purchased by Novartis, RPMI-1640 and 2.05 mM L-glutamine were the major component and get from Thermo Fisher Scientific, there is also a need to add 10 % heat-inactivated human AB serum (Omega Scientific, USA), 55 µM 2-mercaptoethanol and 10 mM of HEPES Buffer (Mediatech, USA), gentamicin(50 µg/mL), penicillin(100 I.U./mL), streptomycin(100 µg/mL) were purchased from Invitrogen and prevent infection (Arneth, 2019).

Western blotting

We investigated the expression of PD-L1, Sema4D, Plexin-B1, PI3K, p-PI3K, AKT, p-AKT, these protein were purchased from Abcam Shanghai Trading Co., LTD and cell signaling

technology, Inc. (Shanghai, China). Total protein was extracted and BCA protein detection kit (Beyotime, China) was used to evaluate the protein concentration. after electrophoresis, transfer membrane, antibody incubation process, an ECL chromogenic substrate was applied for detecting the signals (Beyotime, China).

RT-qPCR

Total RNA was obtained by processing the samples with TRIzol reagent and Dnase-free DNase Set (Beyotime, China) . The synthesis of complementary DNA was performed using a cDNA synthesis kit (Thermo Fisher Scientific, USA). Finally, RT-PCR analysis was performed using an ABI PRISM 7900-HT sequence detection system (Applied Biosystems, USA). For qRT-PCR, the following primers were used.

PD-L1: 5'-AGAACCTGGCTGCACCTAAC-3'(F),
5'-GAGAAGGTCAAACCGCCTCA-3'(R);
Plexin-B1: 5'-AAGCCAGCCTACTAACAACC-3'(F),
5'-CAGCCCCACTGTACTGACTG-3'(R);
Sema4D: 5'-TCAAAGCAGACGGAATGCCTA-3'(F),
5'-CCCCAACCATGACTGATGTGTA-3'(R);
GAPDH: 5'-TTGTCATGGGAGTGAACGAGA-3'(F),
5'-CAGGCAGTTGGTGGTACAGG-3'(R).

shRNA and expression plasmid transfection

Short hairpin RNA (shRNA) targeting Sema4D and the lentivirus containing this shRNA were designed and synthesized by Genepharma Co. (Shanghai, China), sh-sema4D (5'-GGATGGGACTG TCTATGATGT-3') and the control NC-sema4D (5'-TTCTCCGAACGTGTCACGT-3'). The shuttle plasmid and three other packaging plasmids (pGag/Pol, pRev, pVSV- G) were co-transfected into 293T cells to generate a lentivirus expressing Sema4D shRNA or a control lentivirus expressing shRNA. Cells were inoculated into 6-well plates at 1×10^5 and infected with lentivirus while 5 μ g/mL of Polybrene was added. The culture media was changed after 24 hours of infection, and the infected cells were screened with 1 μ g/mL of puromycin for 7 days after the culture media change to obtain stable lentiviral shRNA expressing cell lines for subsequent experimental analysis (Moore et al., 2010).

MTT

Cell viability was measured by MTT assay. 1×10^4 B16-F10R cells were cultured and transfected with Sema4D-shRNA and Sema4D-NC after 24 hours, so cell were divided into Sema4D-shRNA and Sema4D-NC group, and these two groups were co-cultured with TIL at a 1:5 ratio (van den Berg et al., 2020) and nivolumab 50 ng/mL for 24 hours. MTT was dissolved in DMSO and 0.5 mg/mL MTT diluted in 1 \times PBS for 4 hours, Turn on Benchmark Plus microplate reader (Bio-Rad, American) and detect absorbance at 570 nm (Algazi et al., 2020).

Cell apoptosis analysis

Cell apoptosis were detected by AnnexinV-AlexaFluor647/PI Kit Apoptosis Assay Kit(Biotech, China). 5×10^5 B16-F10R cells were seeded in 10-cm culture dishes (Corning, USA) and incubated overnight. Cells were divided into Sema4D-shRNA and Sema4D-NC group which transfected with Sema4D-shRNA and Sema4D-NC respectively, co-cultured with TIL at a 1:5 ratio and nivolumab 50 ng/mL for 24 hours. 5×10^5 cells were collected and resuspended with 500 μ L binding buffer. 5 μ L Annexin V/AlexaFluor647 were incubate for 5 minutes at room temperature, then add 10 μ L propidium iodide (PI), fluorescent dyes should be protected from light.

Wound healing and invasion analysis

B16-F10R cells were divided into Sema4D-shRNA group and Sema4D-NC group. cell invasion and migration was analyzed by Matrigel-coated invasion chambers and scratch assay. The initial number of cells cultured was 5×10^5 , a sterile 10 μ L pipette tip was used to mark a line in the monolayer of each well, the wounds were observed at 0, 24 and 48 hours under a microscope (Nikon, Japan). ImageJ software was used to measure the wound areas. Cell free migration area=(cell free area 0h - cell free area 24hs)/cell free area 0h (Ji et al., 2018). Matrigel-coated invasion chambers (Corning, USA) was used to incubation with 48 hours. The top of Matrigel and invading cells were fixed and stained with 0.1% crystal violet. The microscope (Nikon, Japan) was used to photograph invading cells, and 3 fields were randomly selected and counted each time.

Animal and tumorigenesis

Balb/c mice with 12-week-old were purchased from Chendu dossey experimental animals CO., LTD (SCXK (Chuan) 2020-030, Chengdu, China). The mice were fed unrestricted diet and water intake, and were kept under specific pathogen-free conditions in a laboratory where a 12-hour light/dark cycle was strictly enforced (SYXK (Chuan) 2018-065, Luzhou, China). According to the minimum requirements of congeners, there were six mice in each group of the same strain, making a total of 12 mice (Sanmamed et al., 2015), according to the random count table, mice were divided into Sema4D-shRNA group and Sema4D-NC group randomly, six mice in each group were labeled with picric acid as head, neck, back, left back, right back, and left forelimb. B16-F10R-Sema4D-shRNA cells and B16-F10R-Sema4D-NC cells were intradermal injected into the right side of two group mice respectively, so Sema4D-NC group is the control group, then intraperitoneally injected nivolumab 10 mg/kg once at day 1, 1 mice of Sema4D-NC group was died during the experiment. Tumor volumes were measured on 1, 3, 6, 9, 12, 15 and 18 days with caliper, at days 18, the mice were anesthetized with 10% chloral hydrate and sacrificed by cervical dislocation, tumor weight was measured, tumor volumes were calculated with the formula: tumor volume = $0.52 \times \text{length} \times \text{width}^2$. The people who make the models are different from the people who measure the tumors, and the tumor testers don't know the grouping and the measured data are handed over to the statisticians for processing. All experimental protocols were approved by the ethic committee (Southwest medical university, China) and in compliance with the international regulations on care and protection of laboratory animals (SWMU20210429).

Data collection

Melanoma gene expression profiling data were extracted from the Cancer Genome Consortium (TCGA) database using the "TCGAbiolinks" software package. Expression profiles were converted to transcripts per million mapped reads per kilobase exon model (TPM) and normalized by log2.

Weighted co-expression network analysis

To explore the signaling pathways involved in Sema4D, gene co-expression network analysis (WGCNA) was first conducted to determine genes with significant change between high- and low- expression of Sema4D through "WGCNA" package on R project. Topological overlapping measurement was utilized to identify modules most associated with Sema4D expressions. Correlation between modules and traits is calculated by Spearman correlation analysis.

Protein-Protein interaction

To explore the potential functions played by Sema4D in various biological processes, we constructed Sema4D-related protein-protein interaction network by STRING (<https://cn.string-db.org/>).

Gene set variation analysis

Gene set variation analysis was conducted to reveal the molecular mechanisms under the different Sema4D expression populations in melanoma. The h.all.v7.5.1.symbols.gmt gene set was used to enrichment analysis and was downloaded from MSigDB (<https://www.gsea-msigdb.org/gsea/index.jsp>).

Functional enrichment analysis of Sema4D

To explore the mechanism of action of Sema4D involved in PD-1 inhibitor resistance, enrichment analysis on hub genes was performed. "ClusterProfiler" package in R project was utilized to identify the signaling pathways involved in Sema4D within TCGA cohort (which contains 471 melanoma samples).

Statistical analysis

Tumor size, apoptosis rate and other measurement data were expressed as mean plus or minus standard deviation. GraphPad Prism V.7.00 software was utilized for statistical analysis. Different statistical methods were selected according to different experimental purposes, compare the differences between two groups, we chose Student's t test, one-way ANOVA was used to compare the differences between the overall differences. $P < 0.05$ is considered to be statistically significant.

RESULTS

Sema4D and Plexin-B1 overexpression in anti-PD-1 resistance melanoma cells

To investigate the mRNA and protein expression of Sema4D and Plexin-B1 in B16-F10R and

B16-F10 groups, Sema4D and Plexin-B1 were detected. Compared with B16-F10 group, mRNA and protein expression of Sema4D and Plexin-B1 were significantly overexpressed in B16-F10R group (*Figure 1A-E*).

Sema4D deficiency inhibit PD-L1 expression upon anti-PD-1 therapy

We analyzed the correlation of PD-L1 and Sema4D with bioinformatics, it showed that PD-L1 and Sema4D are positively correlated (*Figure 2A*). Compared with Sema4D-NC group, mRNA and protein expression of PD-L1 in Sema4D-shRNA group was significantly downregulated after nivolumab treatment (*Figure 2B, C, D*), which was consistent with the results of bioinformatics. Therefore, inhibition of SEMA4D significantly repressed the mRNA and protein expression of PD-L1.

Sema4D deficiency potentiates anti-PD-1 treatment efficacy

To explore the relationship between Sema4D deficiency and anti-PD-1 treatment efficacy in B16-F10R cells, we investigated the cell viability and cell apoptosis. The results showed Sema4D deficiency potentiates anti-PD-1 treatment efficacy in B16-F10R cells. Compared with Sema4D-NC group, the cell viability of Sema4D-shRNA group in combination with anti-PD-1 is decreased significantly (*Figure 3A*) and rate of apoptosis cell in Sema4D-shRNA group after treatment with anti-PD-1 is notably increased (*Figure 3B, C*). In vivo experiment, we transplanted B16-F10R cells in the mice and observed the size and weight of tumors treated with nivolumab, tumor volume and weight were significantly delayed in Sema4D-shRNA group mice as compared to Sema4D-NC group mice (*Figure 3D, E, F*).

Sema4D deficiency potentiates the inhibitory effect of anti-PD-1 on cell invasion and migration

The affection of Sema4D deficiency with anti-PD-1 treatment on B16-F10R cell invasion and migration was analyzed by Matrigel-coated invasion chambers and scratch assay. The results showed that when knockdown of Sema4D, cell migration of Sema4D-shRNA group was decreased ($P < 0.0001$), cell migration of Sema4D-shRNA group was wider than those of Sema4D-NC group cells (*Figure 4A, B*). In addition, the number of invaded cells was significantly less in Sema4D-shRNA group in contrast to Sema4D-NC group (*Figure 4C, D*), these data suggesting that lowering Sema4D could enhance the inhibitory effect of anti-PD-1 on cell migration and invasion.

Downregulation of Sema4D inhibit PI3K/AKT expression

The brown module was determined to be most significantly associated with Sema4D expression ($r = +0.67$, $p\text{-value} = 1e-62$), which contained a total of 778 genes (*Figure 5A-B*). Gene set variation analysis (GSVA) revealed several significantly upregulated malignancy-associated events (IL-6, JAK, STAT3, MTORC1, and KRAS signaling pathways) in the Sema4D high expression group as well as downregulation of p53 signaling (*Figure 5C*). Sema4D was significantly associated with oncogenes RHOA, RRAS and immunomodulatory-related genes

PTPRC and PLXNC1 (**Figure 5D**). Pathway enrichment analysis revealed that Sema4D is involved in multiple immune-related pathways as well as the PI3K/AKT pathway (**Figure 5E**). Numerous studies have demonstrated that excessive activation of PI3K/AKT signaling pathway is associated with excessive proliferation of tumor cells, inhibition of apoptosis and attenuation of the efficacy of immune checkpoint inhibitors (Zhang et al., 2022). The expression of PI3K/AKT protein was explored by Western blot. p-PI3K/PI3K, p-AKT/AKT of Sema4D-shRNA group were decreased than those of Sema4D-NC group, which suggesting aberrant activation of the PI3K/AKT signaling pathway in the Sema4D-NC group (**Figure 5F**).

DISCUSSION

Immunotherapy is one important method for melanoma, PD-1 and PD-L1 are two of the most attractive new immune checkpoints, for melanoma patients, when alone or in combination with anti-PD-1 and anti-PD-L1 may improve survival rates (Simeone et al., 2015). Nivolumab is a PD1 inhibitor that has anti-melanoma effects with high affinity to PD-1 (Hirano et al., 2005). However, the ineffectiveness or resistance of anti-PD-1 to melanoma is a serious problem. In general, anti-PD-1 resistance are mainly divided into acquired resistance and innate resistance (Bridgeman et al., 2014, Marincola et al., 2000, Bronte et al., 2005, O'Donnell et al., 2017). The causes of anti-PD-1 or anti-PD-L1 resistance to melanoma are very complex and the genes involved are not fully understood. This study elucidated the mechanism of anti-PD-1 resistance is associated with PI3K/AKT signaling pathway via Sema4D expression.

Sema4D expressed on T cells and many cancers, when it combined with Plexin-B1, it correlates with tumor immune infiltration, angiogenesis, and tumor progression in melanoma (Lu et al., 2021). In this study, we explored mRNA and protein expression of Sema4D and Plexin-B1 in mouse melanoma tumor cell lines and drug-resistant cell lines, our results revealed that the mRNA and protein expression of Sema4D and Plexin-B1 in drug-resistant cell lines were overexpressed. Therefore, we provide the evidence for the first time that Sema4D/Plexin-B1 is related to anti-PD-1 resistance of melanoma.

To understand the expression of Sema4D in melanoma resistance to anti-PD-1, we inhibited Sema4D expression by shRNA in combination with anti-PD-1 (Nivolumab). It was observed that downregulation of Sema4D sensitized B16-F10R cells to nivolumab by inhibiting the growth of tumor cells and reducing cell invasion and migration. As reported by Rezaeepoor that silencing of Sema4D serve as a therapeutics target for the suppression of invasion, migration (Rezaeepoor et al., 2021).

In addition, we also investigated the effects of Sema4D knockdown on B16-F10R cells apoptosis in response to nivolumab. We found that rate of apoptosis cell in Sema4D-shRNA group after treatment with anti-PD-1 is markedly increased. A study conducted by Rashidi illustrated silencing of Sema4D can elevated apoptosis rate of SW48 cells in response to 5-FU treatment (Rashidi et al., 2020). Moreover, we verified the enhancement of anti-PD-1 sensitivity by Sema4D knockdown in vivo xenograft models, mice treated with nivolumab after Sema4D knockdown showed significantly slower tumor growth. Taken together, these finding demonstrated that Sema4D deficiency can potentiates anti-PD-1 treatment efficacy.

We further analyzed the correlation between Sema4D and PD-L1 expression in anti-PD-1 resistance. It has been demonstrated that the presence of PD-L1 determines the response to anti-PD-1 /PD-L1 therapy (Sunshine et al., 2017), regorafenib can promotes antitumor immunity via inhibiting PD-L1 expression in melanoma (Wu et al., 2019). JAK1/2 mutation leads to the lack of reactive PD-L1 expression, which is involved in the resistance of PD-1/PD-L1 inhibitors (Shin et al., 2017). In this study, we evaluated PD-L1 expression in B16-F10R cell when knockdown with Sema4D-shRNA, the results showed PD-L1 expression in Sema4D knockdown group is decrease, it suggest that the effects of Sema4D knockdown on Nivolumab in B16-F10R cell lines may be related to the decrease of PD-L1 expression. However, which way contributes to the PD-L1 downregulation after knockdown Sema4D remains unclear and needs further investigation.

Bioinformatics analysis revealed that Sema4D is involved in the PI3K/AKT signaling pathway which is activated and plays important roles such as being involved in the development and occurrence in melanoma and it also activate receptor tyrosine kinases (Davies, 2012). PI3K is phosphorylated by binding to GRB2, and AKT phosphorylates target genes to regulate cell function (Pu et al., 2021). Sema4D/ plexin-B1 is associated with osteosarcoma, in which PYK2-PI3K-Akt pathway is activated to promote tumor progression(Li et al., 2021). To explore the relationship between Sema4D and PI3K/AKT signaling pathways in anti-PD-1 resistance, we detected the expression of PI3K/AKT protein, in B16-F10R cell, p-PI3K/PI3K, p-AKT/AKT expression were significantly increased, when inhibited the Sema4D, p-PI3K/PI3K, p-AKT/AKT expression of Sema4D-shRNA group were decreased, these shown that Sema4D can regulate PI3K/AKT expression and activity.

However, this study only examined the differences in Sema4D expression between sensitive cells and resistant cells , and the effects of nivolumab on cells and animals after Sema4D blockade were also evaluated. In this study , the number of cell lines involved and the methods of blocking Sema4D in animals were limited, so in future studies, we will further expand the cell types and try to study the mechanism of Sema4D in vivo.

In conclusion, we explored the role of Sema4D/Plexin-B1 in the process of PD-1 inhibitor resistance. In anti-PD-1 resistant cell line, upregulation of Sema4D/Plexin-B1 was observed. When Sema4D was downregulated, it prevented the phosphorylation of PI3K and AKT, thus inhibiting the PI3K/AKT pathway activity. Therefore, these results may have therapeutic implication and may be exploited for the development of novel treatment for anti-PD-1 resistance melanoma in the future.

Figure Legends

Figure 1. | Sema4D/Plexin-B1 expression in cells. Cells were divided into B16-F10R group(B16-F10R cells) and B16-F10 (B16-F10 cells), 24 hours after cell culture, Sema4D/Plexin-B1 expression were detected. (A) Protein bands of Sema4D and Plexin-B1. (B) Ratio to GAPDH of Sema4D. (C) Ratio to GAPDH of Plexin-B1. (D) mRNA expression of Sema4D. (E) mRNA expression of Plexin-B1. Compared with B16-F10 group, Sema4D and Plexin-B1 were significantly upregulated in B16-F10R group. * is $p<0.05$, ** is $P<0.01$.

Figure 2. | Sema4D deficiency inhibit PD-L1 expression. B16-F10R Cell were divided into Sema4D-shRNA group and Sema4D-NC group, co-cultured with TIL at a 1:5 ratio and nivolumab 50 ng/ml 24 hours, collect the cell to detect the expression of PD-L1. (A) Correlation between PD-L1 and Sema4D (B) Protein bands of PD-L1. (C) Ratio to GAPDH of PD-L1. (D) mRNA expression of PD-L1. Compared with Sema4D-NC group, ** is $p<0.01$, *** is $P<0.001$.

Figure 3. | Sema4D deficiency potentiates anti-PD-1 treatment efficacy. (A) cell viability after

treatment with anti-PD-1. (B) cell apoptosis rate after treatment with anti-PD1. (C) Bar graph of apoptosis rate after treatment with anti-PD1. (D) Tumor volume of knockdown Sema4D with anti-PD-1 treatment. (E) Tumor weight of knockdown Sema4D with anti-PD-1 treatment. (F) Tumor of Sema4D-shRNA(n=6) and Sema4D-NC mice(n=5). Compared with Sema4D-NC group, ** is $p<0.01$, *** is $p<0.001$, **** is $p<0.0001$.

Figure 4. | Sema4D deficiency potentiates the inhibitory effect of anti-PD-1 on cell invasion and migration. Cells were divided into Sema4D-shRNA group and Sema4D-NC group, co-cultured with TIL at a 1:5 ratio and nivolumab 50 ng/ml 24hours, cell invasion and migration were detected, wound healing analysis showed a significant difference in the cell-free area of Sema4D-shRNA group was significantly wider than that of Sema4D-NC group at 24 and 48 hours ($P < 0.0001$). Chamber invasion analysis showed a significant difference lower number of invasive cells in Sema4D-shRNA group than Sema4D-NC group ($\times 100$). (A) Representative image of cell migration in the absence and presence of shRNA Sema4D at 0 h, 24 h, and 48 h. The scratched areas were measured in three random fields in each group. (B) Ratio of cell free area (C) chamber invasion of cell (D) cell invasion number per field. Compared with Sema4D-NC group, **** is $p<0.0001$.

Figure 5. | Sema4D knockdown is significantly associated with inhibition of PI3K-AKT signaling pathway. (A) Association of clustered modules with Sema4D expression. The brown module was identified as the most relevant module for Sema4D expression. (B) Module-trait associations. (C) Gene set variation analysis revealed several significantly dysregulation malignancies events between different Sema4D expression population. (D) Protein-protein interactions of Sema4D. (E) Pathway enrichment analysis showed that Sema4D is involved in the PI3K-AKT signaling pathway. (F) Western blotting showed that knockdown of Sema4D was significantly associated with inhibition of PI3K-AKT signaling pathway. Compared with Sema4D-NC group, ** is $p<0.01$.

Figure 1

Sema4D/Plexin-B1 expression in cells. Cells were divided into B16-F10R group(B16-F10R cells) and B16-F10 (B16-F10 cells), 24 hours after cell culture, Sema4D/Plexin-B1 expression were detected.

(A) Protein bands of Sema4D and Plexin-B1. (B) Ratio to GAPDH of Sema4D. (C) Ratio to GAPDH of Plexin-B1. (D) mRNA expression of Sema4D. (E) mRNA expression of Plexin-B1. Compared with B16-F10 group, Sema4D and Plexin-B1 were significantly upregulated in B16-F10R group. * is $p < 0.05$, ** is $P < 0.01$.

Figure 2

Sema4D deficiency inhibit PD-L1 expression. B16-F10R Cell were divided into Sema4D-shRNA group and Sema4D-NC group, co-cultured with TIL at a 1:5 ratio and nivolumab 50 ng/ml 24 hours, collect the cell to detect the expression of PD-L1.

(A) Correlation between PD-L1 and Sema4D (B) Protein bands of PD-L1. (C) Ratio to GAPDH of PD-L1. (D) mRNA expression of PD-L1. Compared with Sema4D-NC group, ** is $p < 0.01$, *** is $P < 0.001$.

Figure 3

Sema4D deficiency potentiates anti-PD-1 treatment efficacy.

(A) cell viability after treatment with anti-PD-1. (B) cell apoptosis rate after treatment with anti-PD1. (C) Bar graph of apoptosis rate after treatment with anti-PD1. (D) Tumor volume of knockdown Sema4D with anti-PD-1 treatment. (E) Tumor weight of knockdown Sema4D with anti-PD-1 treatment. (F) Tumor of Sema4D-shRNA and Sema4D-NC mice. Compared with Sema4D-NC group, ** is $p<0.01$, *** is $p<0.001$, **** is $p<0.0001$.

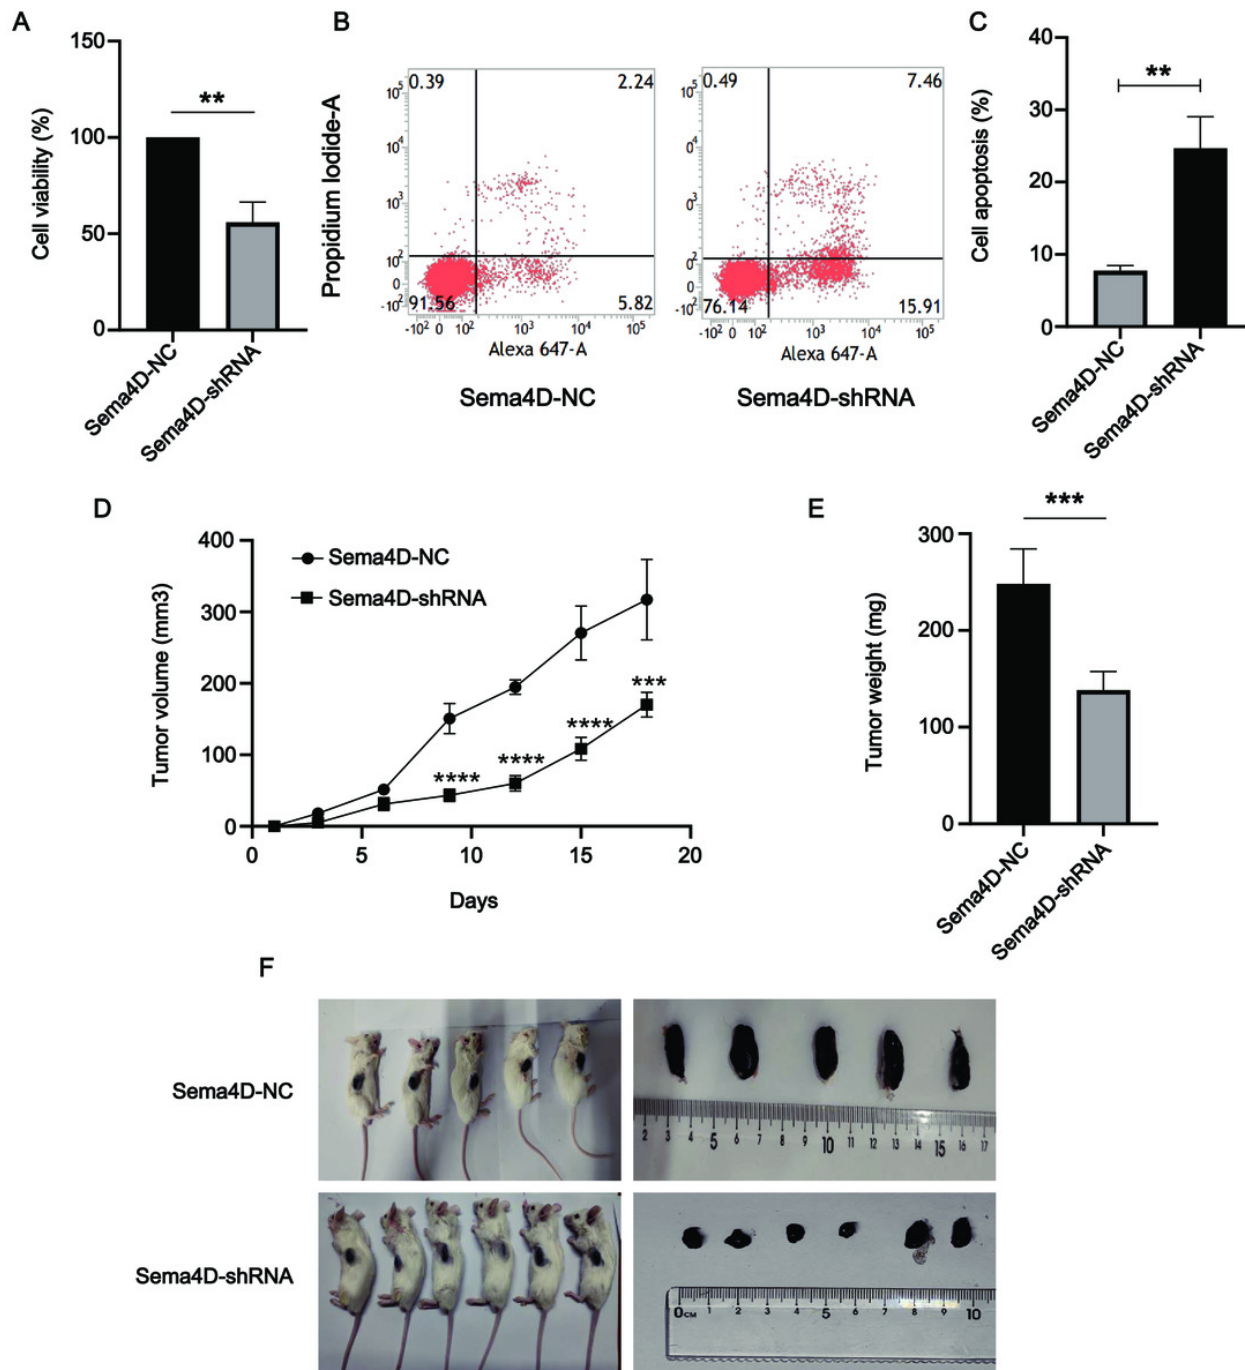

Figure 4

Sema4D deficiency potentiates the inhibitory effect of anti-PD-1 on cell invasion and migration.

(A) Representative image of cell migration in the absence and presence of shRNA Sema4D at 0 h, 24 h, and 48 h. The scratched areas were measured in three random fields in each group. (B) Ratio of cell free area (C) chamber invasion of cell (D) cell invasion number per field. Compared with Sema4D-NC group, **** is $p < 0.0001$.

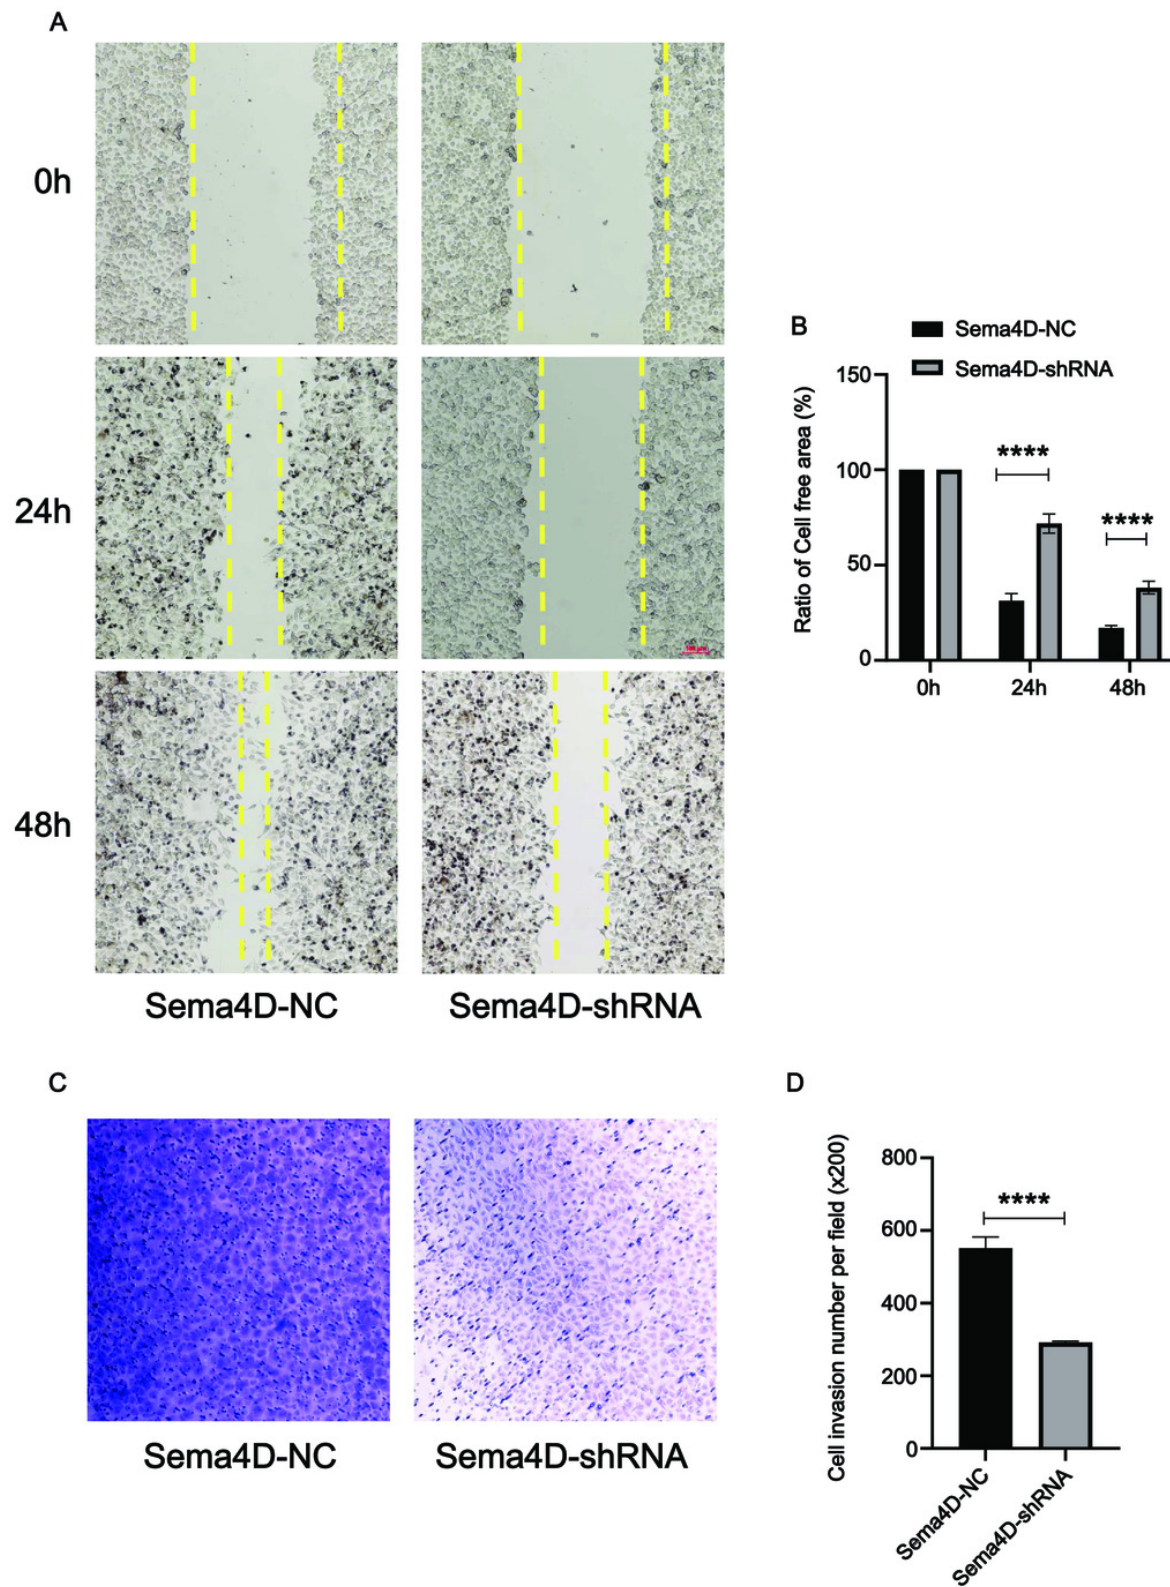

Figure 5

Sema4D knockdown is significantly associated with inhibition of PI3K-AKT signaling pathway.

(A) Association of clustered modules with Sema4D expression. The brown module was identified as the most relevant module for Sema4D expression. (B) Module-trait associations. (C) Gene set variation analysis revealed several significantly dysregulation malignancies events between different Sema4D expression population. (D) Protein-protein interactions of Sema4D. (E) Pathway enrichment analysis showed that Sema4D is involved in the PI3K-AKT signaling pathway. (F) Western blotting showed that knockdown of Sema4D was significantly associated with inhibition of PI3K-AKT signaling pathway. Compared with Sema4D-NC group, ** is $p<0.01$.
