The kukri snakes of the genus *Oligodon* Fitzinger, 1826 reach the westernmost limits of their distribution in Middle and Southwest Asia (Pakistan, Afghanistan, Iran, and Turkmenistan). In this paper, we review the taxonomy and distribution of the two species native to this region, *Oligodon arnensis* (Shaw, 1802) and *Oligodon taeniolatus* Jerdon, 1853 based on an integrative approach combining morphological data, molecular data from mitochondrial DNA, and species distribution modeling (SDM). Phylogenetic analyses recover *O. taeniolatus* from Iran and Turkmenistan in the *O. arnensis* species group, rendering the species paraphyletic with respect to *O. taeniolatus* sensu stricto on the Indian subcontinent. To correct this, we resurrect the junior synonym *Contia transcaspica* Nikolsky, 1902 for the Middle/Southwest Asian populations and provide a formal redescription. So far, *Oligodon transcaspicus* **comb. et stat. nov.** is known only from the Köpet-Dag Mountain Range of northeast Iran and southern Turkmenistan, but SDM mapping suggests it may have a wider range. Genetic samples of *O. "arnensis"* from northern Pakistan are nested in a clade sister to the recently described *Oligodon churahensis* Mirza, Bhardwaj & Patel, 2021, and are phylogenetically separate from *O.*

arnensis sensu stricto in south India and Sri Lanka. Based on morphological similarity, the Afghanistan and Pakistan populations are assigned to *Oligodon russelius* (Daudin, 1803) and we synonymize *O. chuarhensis* with this species. Our investigation leads us to remove *O. taeniolatus* from the snake fauna of Afghanistan, Iran, and Turkmenistan, with the consequence that only *Oligodon transcaspicus* **comb. et stat. nov.** and *O. russelius* are present in these countries. Additional studies are needed to resolve the taxonomy of the *O. taeniolatus* and *O. arnensis* species groups on the Indian subcontinent.

33 Abstract

34 The kukri snakes of the genus *Oligodon* Fitzinger, 1826 reach the westernmost limits of their
35 distribution in Middle and Southwest Asia (Pakistan, Afghanistan, Iran, and Turkmenistan). In
36 this paper, we review the taxonomy and distribution of the two species native to this region,
37 *Oligodon arnensis* (Shaw, 1802) and *Oligodon taeniolatus* Jerdon, 1853 based on an integrative
38 approach combining morphological data, molecular data from mitochondrial DNA, and species
39 distribution modeling (SDM). Phylogenetic analyses recover *O. taeniolatus* from Iran and
40 Turkmenistan in the *O. arnensis* species group, rendering the species paraphyletic with respect to
41 *O. taeniolatus* sensu stricto on the Indian subcontinent. To correct this, we resurrect the junior
42 synonym *Contia transcaspica* Nikolsky, 1902 for the Middle/Southwest Asian populations and
43 provide a formal redescription. So far, *Oligodon transcaspicus* **comb. et stat. nov.** is known only
44 from the Köpet–Dag Mountain Range of northeast Iran and southern Turkmenistan, but SDM
45 mapping suggests it may have a wider range. Genetic samples of *O. “arnensis”* from northern
46 Pakistan are nested in a clade sister to the recently described *Oligodon churahensis* Mirza,
47 Bhardwaj & Patel, 2021, and are phylogenetically separate from *O. arnensis* sensu stricto in
48 south India and Sri Lanka. Based on morphological similarity, the Afghanistan and Pakistan
49 populations are assigned to *Oligodon russelius* (Daudin, 1803) and we synonymize *O.*
50 *chuarhensis* with this species. Our investigation leads us to remove *O. taeniolatus* from the snake
51 fauna of Afghanistan, Iran, and Turkmenistan, with the consequence that only *Oligodon*
52 *transcaspicus* **comb. et stat. nov.** and *O. russelius* are present in these countries. Additional
53 studies are needed to resolve the taxonomy of the *O. taeniolatus* and *O. arnensis* species groups
54 on the Indian subcontinent.

55 Keywords

57 Mountain Range, Indian subcontinent, Taxonomy, mtDNA, species distribution modeling

58 Introduction

59 Our knowledge of the snake fauna of Middle and Southwest Asia (herein considered the
60 countries of Afghanistan, Iran, Pakistan, western China, Mongolia and the former Soviet Middle
61 Asian republics fide Berg, 1931; Geptner, 1938; Chernov, 1949) has improved over the past
62 decade as researchers continue to contribute species descriptions, range extensions, and natural
63 history observations (Wagner et al., 2016a; Jablonski & Koleska, 2017; Farooq et al., 2018;
64 Rajabizadeh, 2018; Shestopal & Rustamov, 2018a; Shestopal & Rustamov, 2018b; Orlov et al.,
65 2018; Jablonski et al., 2019; Asadi et al., 2019; Rajabizadeh et al., 2020; Eskandarzadeh et al.,
66 2020; Chen et al., 2021; Essote et al., 2022). Most snake species inhabiting these countries are
67 associated with the Palearctic biogeographic realm. However, there also exist a few taxa
68 originating from the Oriental realm (South and Southeast Asia) that reach their westernmost
69 limits in this region (Wagner et al., 2016b; Orlov et al., 2018). The kukri snakes of the genus
70 *Oligodon* Fitzinger, 1826 are one such example. Normally distributed across tropical portions of

71 South and Southeast Asia, two species of this diverse group extend into Afghanistan,
72 northeastern Iran, Pakistan, and southern Turkmenistan (Latifi, 1991; Green, 2010; Wagner et
73 al., 2016b; Orlov et al., 2018; Uetz et al., 2022).

74 The first species, the banded kukri snake *Oligodon arnensis* (Shaw, 1802), is commonly
75 found across the Indian subcontinent, but is known from Afghanistan based on a single specimen
76 (Král, 1969; Wagner et al., 2016b). This species was recently divided into several taxa by
77 Bandara et al. (2022), who published a revision of *O. arnensis* sensu auctorum based largely on
78 morphological data. These authors restricted *O. arnensis* sensu stricto to southern India and Sri
79 Lanka, and described a new species *Oligodon tillacki* Bandara et al., 2022 (Tillack's kukri snake)
80 for *O. arnensis* populations found along the western coast of India, and the resurrected the name
81 *Oligodon russelius* (Daudin, 1803) (Russell's kukri snake) for populations in north/east India,
82 Bangladesh (Barkat & Rabbe, 2022) and Nepal (Rai, Adhikari & Antón, 2022). Additionally,
83 Mirza, Bhardwaj & Patel (2021) described a new species, the Churah Valley kukri snake *O.*
84 *churahensis* Mirza, Bhardwaj & Patel, 2021 from Himachal Pradesh, India, which was recovered
85 within *O. arnensis* species group based on mitochondrial DNA (mtDNA) sequences. These
86 authors included genetic samples of *O. "arnensis"* collected from Pakistan but were unable to
87 examine their specimen vouchers and tentatively identified them as *Oligodon cf. churahensis*.
88 While these studies have shed light on the taxonomic nature of the *O. arnensis* and related taxa,
89 both neglected the status of specimens from Pakistan and Afghanistan. We refer to these
90 populations as *O. "arnensis"* until our clarifications in the results.

91 The second species, the streaked kukri snake *Oligodon taeniolatus* (Jerdon, 1853), is also
92 widespread on the Indian subcontinent, but extends westward into northern Iran, southern
93 Turkmenistan, and possibly Afghanistan (Latifi, 1991; Wagner et al., 2016b; Orlov et al., 2018).
94 Like *O. "arnensis"*, *O. taeniolatus* exhibits substantial variation across its range, including
95 multiple color phenotypes that have invariably been recognized as synonyms or subspecies by
96 past authors (Wall, 1921; Wall, 1923; Smith, 1943; Taylor, 1950). Bauer (2003) reviewed the
97 nomenclatural history of this taxon and designated a lectotype illustrated by Russell (1796) with
98 the type locality "Vizagapatam" (=Visakhapatnam, Andhra Pradesh, India), thereby restricting
99 'true' (nominotypical) *O. taeniolatus* to eastern India. Outside of South Asia, populations of *O.*
100 *taeniolatus* from Iran and Turkmenistan can be referred to the name *Contia transcaspica*
101 Nikolsky, 1902, described based on a single specimen collected from "Köpet-Dag, Transcaspia"
102 [=now Köpet-Dag Mountain Range, near Ashgabat, Ahal Province, Turkmenistan]. Chernov
103 (1935) considered *C. transcaspica* to be a junior synonym of *O. taeniolatus*, owing to similarities
104 between Turkmen and Indian specimens. Later authors would follow his recommendation and
105 report these populations as *O. taeniolatus* in the subsequent literature (Terentjev & Chernov,
106 1949; Bogdanov, 1962; Bannikov et al., 1977; Dotsenko, 1984; Atayev, 1985; Szczerbak,
107 Khomustenko & Golubev 1986; Latifi, 1991; Rustamov & Sopyev, 1994; Szczerbak, 1994;
108 Atayev, Rustamov & Shammakov, 1994). The name *Contia transcaspica* has rarely been
109 mentioned since and was even neglected in the synonymy of *O. taeniolatus* by Wallach et al.
110 (2014). A few sources (Dotsenko, 1984; Latifi, 1991) would provide additional descriptive data

111 of collected specimens from this region. Their accounts showed that specimens from the Köpet–
112 Dag Mountain Range had distinct differences in coloration and scalation from Indian
113 subcontinent *O. taeniolatus* (Wall, 1921; Wall, 1923; Smith, 1943), although detailed
114 comparisons between populations were not made.

115 In this study, we review the taxonomy, phylogenetic relationships, and distributional
116 limits of the genus *Oligodon* at the westernmost end of its range. We aimed to clarify the
117 taxonomic status of *O. taeniolatus* historically associated with the name *Contia transcaspica*
118 from Iran and Turkmenistan and resolve the status of *Oligodon* “*arnensis*” populations from the
119 countries of Pakistan and Afghanistan, which were neglected by past taxonomic revisors.

120 **Materials & Methods**

121 **Sampling and species delimitation.** Fieldwork which resulted in the collection of *Oligodon* in
122 Iran was conducted by RAN and MR during a field trip in May 2017 to Razavi, Khorasan
123 Province, Iran (locality 7, Figure 1). Fieldwork in Pakistan was conducted by DJ and RM during
124 a field trip in September 2018 to Punjab Province, Pakistan. Fieldwork in Sri Lanka was
125 conducted by SK and NAP during field trips in February 2018 to December 2020 to dry and wet
126 zones of the country. Collected specimens were euthanized using a 20% solution of benzocaine
127 and fixed in formalin before being transferred into 70% ethanol for storage. Before preservation,
128 a small sample of muscle tissue was taken from each snake and stored in 95% ethanol for later
129 DNA analyses. For molecular analysis, we included one sample of *O. taeniolatus* (= *Contia*
130 *transcaspica*) from Iran (ZMMU Re-16687); one sample of nominotypical *O. taeniolatus* from
131 India (CESS-180); four novel samples of *O. arnensis* sensu stricto from India (CESS-563) and
132 Sri Lanka (SL-Os-1, SL-Oa-2; ZMMU Re-17331); two novel samples of *O. sublineatus*
133 Duméril, Bibron & Duméril, 1854 from Sri Lanka (SL-Os-2; SL-Os-3); and one novel sample
134 morphologically resembling *Oligodon russelius* from Punjab Province, Pakistan (CUHC 7904;
135 locality 9, Figure 1). In addition, we included 34 publicly available samples of other *Oligodon*
136 species retrieved from GenBank (Table 1). Bandara et al. (2022) noted that one sample (NCBS-
137 NRC-AA-021) previously identified as *O. “arnensis”* may represent *O. tillacki* but did not
138 examine this specimen. As such, we re-identify this specimen as *O. cf. tillacki* herein. For
139 outgroup taxa, we chose one sample each of *Oreocryptophis porphyraceus* (Cantor, 1839)
140 (subfamily Colubrinae) and *Hebius vibakari* (Boie, 1826) (subfamily Natricinae) due to their use
141 in previous phylogenies of *Oligodon* published in the literature (Nguyen et al., 2020).

142 We examined the morphology of seven *O. taeniolatus* specimens available to us from the
143 Iran and Turkmenistan, including the type specimen of *Contia transcaspica* (localities 1–7,
144 Figure 1). To compare these populations with typical members of the *O. arnensis* species group,
145 we examined two specimens within the range of *O. russelius* fide Bandara et al. (2022) from
146 Andhra Pradesh, India, and southern Nepal (localities 14–16, Figure 1), five specimens of *O.*
147 *arnensis* sensu stricto from southern India and Sri Lanka (localities 18–19, Figure 1) (see
148 Supplementary Material 1), and the new specimen of *O. russelius* collected from Pakistan
149 (locality 9, Figure 1). Additional morphological data for *O. taeniolatus*, the *O. arnensis* species
150 group and other taxa were derived from relevant literature sources (see Morphological analysis).

151 For aspects of species concepts and delimitation, we follow an integrative taxonomic approach
152 (Padial et al., 2010) where a species is supported by a combination of morphological and
153 molecular evidence. In addition, we follow the General Lineage Concept (De Queiroz, 2007),
154 where a species represents a single independent lineage following a separate evolutionary
155 trajectory compared to its congeners. Discrete morphological separation, substantial genetic
156 divergence using standard genetic markers, and evidence of monophyly are all used as
157 supporting evidence for evolutionary independence.

158 Abbreviations for museum collections are as following: CAS: California Academy of
159 Sciences, San Francisco, USA; CUHC: Comenius University Herpetological Collection,
160 Bratislava, Slovakia; MMB: Department of Zoology, Moravian Museum, Brno, Czech Republic;
161 USNM: National Museum of Natural History, Washington, DC, USA; ZISP: Zoological Institute
162 of Russian Academy of Sciences, St. Petersburg, Russia; ZMMU: Zoological Museum of
163 Moscow State University, Moscow, Russia. Additional abbreviations for genetic samples and
164 voucher specimens can be found in Table 1.

165 Field works, including collection of the samples and animals in the field, was performed
166 outside of any protected area, in the framework of a project contract signed by International
167 Center for Science, High Technology and Environmental Sciences, Kerman, Iran (contract
168 number 1.87, issued at 11.04.2008). The contract bears a permission to collect the reptile
169 samples outside of any protected area of Department of the Environment (specified in
170 www.doe.ir) that needed extra permissions. Specimen collection protocols and animal operations
171 followed the Institutional Ethical Committee of International Center for Science, High
172 Technology and Environmental Sciences, Kerman, Iran (certificate number 1.87-1).

173

174 **Molecular analyses.** We extracted total genomic DNA of novel samples from muscle tissue
175 preserved in 95% ethanol using a Qiagen DNAeasy Blood and Tissue Kit following
176 manufacturers protocols. We performed polymerase chain reactions (PCRs) on the extracted
177 DNA to amplify two fragments of mitochondrial DNA (mtDNA): the first fragment including
178 partial sequences of 12S ribosomal RNA (rRNA), transfer RNA (tRNA)-Valine and 16S rRNA
179 (total length up to 1930 bp), and a second fragment including the complete sequence of the gene
180 Cytochrome *b* (*cyt b*) (1,091 bp). Primers used for both PCR and sequencing are summarized in
181 Table S2. PCR protocols for 12S-16S rRNA fragments were adapted from Green et al. (2010).
182 For both primer pairs of 12S and 16S rRNA, we used the following PCR protocol: (1) initial
183 denaturation step at 94°C for 5 min; (2) 35 cycles of denaturation at 94°C for 1 min, annealing at
184 55°C for 1 min and extension at 72°C for 1 min; (3) final extension at 72°C for 10 min; and (4)
185 cooling step at 4°C for storage. For *cyt b* sequences, we used a modified PCR protocol of Chen
186 et al. (2014) with touchdown: (1) initial denaturation step at 94°C for 5 min; (2) 10 cycles of
187 denaturation at 94°C for 1 min, annealing for 1 min with temperature decreasing from 50°C to
188 45°C (with cool-down at 0.5°C per each cycle) and extension at 72°C for 1 min; (3) 24 cycles of
189 denaturation at 94°C for 1 min, annealing at 45°C for 1 min and extension at 72°C for 1 min; (4)
190 final extension at 72°C for 10 min; and (5) cooling step at 4°C for storage. All PCR products

191 were sequenced in both directions by the Evrogen company at the Institute of Bioorganic
192 Chemistry, Russian Academy of Sciences (Moscow, Russia) and at MacroGen Europe
193 (Amsterdam, The Netherlands; <http://www.macrogen-europe.com>). Sequences were assembled
194 and checked using Sequencher 4.9 (GeneCodes). The obtained sequences are deposited in
195 GenBank under the accession numbers OQ092426; OQ099833–OQ099837; and OQ116816–
196 OQ116825 (Table 1).

197 To examine the position of *O. taeniolatus* from Turkmenistan and Iran in a matrilineal
198 genealogy of the genus, we combined newly obtained sequences with all publicly available
199 GenBank sequences of *O. arnensis*, *O. churahensis*, *O. taeniolatus*, *O. cf. tillacki* and one
200 sequence per species of other *Oligodon* (summarized in Table 1). In total, we analyzed mtDNA
201 sequences of 45 specimens, including 43 samples of 33 species of *Oligodon*, with outgroup
202 sequences of *O. porphyraceus* and *H. vibakari* used to root the tree. Nucleotide sequences were
203 initially aligned in MAFFT v.7 (Katoh et al., 2002) with default parameters, and subsequently
204 checked by eye in BioEdit 7.0.5.2 (Hall, 1999) and slightly adjusted for translation when
205 appropriate. We used IQ-TREE web server (<http://iqtree.cibiv.univie.ac.at/>; Trifinopoulos et al.
206 2016) to estimate optimal evolutionary models for the data set analysis using the Akaike
207 Information Criterion (AIC). Mean uncorrected genetic distances (p-distances) were calculated
208 in MEGA 7.0 (Kumar, Stecher & Tamura, 2016). The matrilineal genealogy was inferred using
209 Bayesian inference (BI) and Maximum Likelihood (ML) approaches. The best-fitting model for
210 both BI and ML analyses for 12S–16S rRNA fragments and for the second codon partition of *cyt*
211 *b* was the GTR+G+I model as of DNA evolution suggested by the AIC. For the remaining
212 portions of *cyt b*, the AIC suggested the GTR+G model for the first codon partition, and the
213 HKY+G+I for the third codon partition.

214 ML was conducted using the IQ-TREE web server (Trifinopoulos et al., 2016). BI was
215 conducted in MrBayes 3.2.2 (Ronquist et al., 2012); Metropolis-coupled Markov chain Monte
216 Carlo (MCMCMC) analyses were run with one cold chain and three heated chains for one
217 million generations and sampled every 1000 generations. Two independent MCMCMC run
218 iterations were performed and 100 trees were discarded as burn-in. The convergence of the runs
219 was checked by exploring and examining likelihood plots in TRACER v1.6 (Rambaut et al.,
220 2020), with effective sample sizes (ESS) all above 200. Nodal support for BI was assessed by
221 calculating posterior probabilities (BI PP). *We a priori* regarded tree nodes with BI PP values
222 over 0.95 as sufficiently resolved, while BI PP values between 0.95 and 0.90 were regarded as
223 tendencies. For ML, confidence in nodal topology was estimated via the ultrafast bootstrap
224 approximation algorithm (UFBS; Hoang et al., 2018) with 1,000 bootstrap pseudoreplicates.
225 Nodes having ML UFBS values of 95 and above were *a priori* considered highly supported,
226 while nodes with values of 90–94 were considered well-supported, and nodes with values of 70–
227 89 were considered as tendencies. Lower values were regarded as indicating unresolved nodes
228 (Huelsenbeck & Hillis, 1993).

229

230 **Morphological analysis.** Coloration and pattern were recorded during examination of preserved
231 specimens. For some specimens, live coloration was also recorded from digital images taken
232 before preservation. No statistical analyses were performed between species due to the low
233 sample size of comparative material. All body measurements, except body and tail lengths, were
234 taken under a dissecting microscope using a digital slide-caliper to the nearest 0.1 mm. Body and
235 tail lengths were measured to the nearest millimeter by straightening snakes along a flexible
236 ruler. Methodology for counting ventral and subcaudal scales follow Dowling (1951). The tail tip
237 was not included in the number of subcaudals. Head scale suture angle terminology follows that
238 of Kaiser, O'Shea & Kaiser (2019). Maxillary teeth were counted by examination of the
239 dissected maxillary bone when available, or by carefully removing the gum layer of the maxilla.
240 Sex was determined by ventral incision below the vent to detect the presence or absence of
241 hemipenes. Our data on specimens referable to *Contia transcaspica* were compared and
242 reviewed with relevant literature on *O. taeniolatus* across its distribution (Nikolsky, 1902;
243 Nikolsky, 1903a; Wall, 1921; Wall 1923; Chernov, 1935; Smith, 1943; Minton, 1966; Dotsenko,
244 1984; Latifi, 1991; Khan, 2002).

245 The following linear measurements (all in mm) were taken: snout to vent length (SVL)
246 — measured from the tip of the snout to the vent; tail length (TailL) — measured from the vent
247 to the tip of the tail; total length (TotalL) — sum of SVL and TailL; relative tail length to total
248 length (TailLR) calculated as tail length to total length ratio; head length (HeadL) from the tip of
249 the snout to the posterior margin of the mandible; head width (HeadW) measured at the widest
250 part of the head immediately posterior to the eye; snout length (SnoutL) — distance between the
251 tip of the snout and anterior edge of eye; eye diameter (EyeD) — maximal horizontal length of
252 the eye; frontal scale length (FrontalL); frontal scale width (FrontalW); distance (IOD) — the
253 shortest distance between the eyes; and internarial distance (IND) — distance between the
254 nostrils. Additional morphological characters examined include the number of maxillary teeth
255 (MT); anterior scale rows (ASR) — namely number of scale rows at one head length behind the
256 head; midbody scale rows (MSR) — the number of scale rows at midbody; posterior scale rows
257 (PSR) — number of dorsal scale rows at one head length prior to the vent; dorsal scale row
258 formula (DSR) — a given acronym summarizing the three dorsal scale row counts (i.e., ASR–
259 MSR–PSR); ventral scales (VEN) — the number of belly scales starting from the scale
260 contacting the first dorsal scale row to the vent, excluding the cloacal plate; subcaudal scales
261 (SC) — the number of paired subcaudal scales excluding the terminal scute; total body scales
262 (TOTAL) — the sum of ventral, subcaudal scales and the cloacal plate (included as one scale
263 regardless of whether the plate is single or divided); subcaudal ratio (SCR) — namely the ratio
264 between the number of subcaudal scales and the number of total body scales given as a decimal
265 value; cloacal plate (CP) — the number of terminal ventral scales immediately anterior to vent
266 (given as single for one scale, and divided for two scales); condition of nasal scale (NASAL) —
267 given as either vertically divided, entire, or partially divided; condition of loreal scale
268 (LOREAL) — given as present or absent; supralabials (SL) — the number of scales on upper lip;
269 number of supralabials in contact with the eye (SL-Eye); infralabials (IL) — the number of

270 scales on lower lip; infralabials contacting each other (IL-contact) — the number of pairs of
271 infralabial scales in contact; infralabials contacting the anterior chin shields (IL-CS) — the
272 number of infralabial scales contacting the anterior chin shields; number of preocular scales
273 (PrO); number of presubocular scales (PrsO); number of postocular scales (PtO); number of
274 anterior temporals (Ate) — the number of temporal scales in contact with the postocular scales;
275 number of posterior temporals (Pte) — the number of temporal scales immediately contacting
276 the anterior temporal scales. We also describe and abbreviate certain color pattern characteristics
277 found in specimens, including the number of body blotches or crossbars from nape to vent (B-
278 Blotch); the number of blotches or crossbars from vent to tail tip (T-Blotch); the width in
279 vertebral (dorsal) scales of each blotch at midbody (BlotchW); and the distance between each
280 blotch at midbody counted using vertebral (dorsal) scales (BlotchD). Abbreviations for these
281 characters are used in Tables 3–4. Symmetric characters are given in left/right order.

282

283 **Species distribution modeling.** We used MaxEnt 3.3.3 (Phillips, Anderson & Schapire, 2006)
284 and modelled the potential distribution of *Oligodon* population in Central Asia in the present as
285 well as three previous historical epochs: the mid-Pliocene (ca 3.2 Mya), the Last Glacial
286 Maximum (ca 21 Kya), and the mid-Holocene (ca 6 Kya). We used 23 unique georeferenced
287 data points (Table S1), 23 bioclimatic and four landscape layers. Data were filtered and
288 correlated variables were excluded using ENMTools 1.3. (Warren et al., 2010) and models
289 assessed by computing the area under the CURVE (AUC). Further, we estimated the relative
290 contribution of variables to the model. For the current climate projection, we used the CHELSA
291 database (Karger et al., 2017). The PaleoCLIM database was used for the past conditions, the
292 mid-Pliocene, the Last Glacial Maximum (LGM) and the Mid-Holocene (Fordham et al., 2017;
293 Brown et al., 2018), at 5 km pixel size. The final maps were designed in QGIS Desktop 3.28
294 software (QGIS Development Team, 2021).

295 Results

296 **Molecular analyses.** The final concatenated alignment of the 12S–16S rRNA and *cyt b* gene
297 sequences contained 3019 base pairs with 1812 conserved sites, 1191 variable sites, and 833
298 parsimony informative sites. The transition-transversion bias (R) was estimated as 1.2.
299 Nucleotide frequencies were 36.7% (A), 23.0% (T), 25.7% (C), and 14.6% (G) (all data given for
300 ingroups only). The uncorrected pairwise genetic distances (hereafter p-distances; given for the
301 *cyt b* mtRNA gene fragment) between and within examined *Oligodon* species are presented in
302 Table 4. Intraspecific genetic distances varied from $p = 0\%$ (in *O. sublineatus*) to $p = 2.2\%$ (*O.*
303 *churahensis*, including samples of *O. cf. churahensis* and *O. russelius*). The interspecific genetic
304 distances within examined *Oligodon* varied from $p = 3.3\%$ (between *O. arnensis* sensu stricto
305 and *O. churahensis*) to $p = 21.0\%$ (between *O. sublineatus* and *O. churahensis*).

306 In general, our mtDNA-based genealogy of *Oligodon* (Figure 2) correlates well with the
307 set of phylogenetic relationships obtained from previous authors (Green et al., 2010; Nguyen et
308 al., 2020; Mirza, Bhardwaj & Patel, 2021; Das et al., 2022; Yushchenko & Lee et al., *in press*).
309 Both ML and BI topologies of our mtDNA-genealogy of *Oligodon* support the specimen of *O.*

310 *taeniolatus* from Iran as a separate lineage sister to *Oligodon melaneus* Wall, 1909, the newly
311 described species *O. churahensis*, and Pakistani specimens *O. russelius* and *O. cf. churahensis*,
312 with strong support from both analyses (0.97/92). Genetic p-distances in this clade varied from
313 7.8% (between *O. taeniolatus* and *O. melaneus*), 6.3% (between *O. taeniolatus* and *O. russelius*),
314 and 5.7% (between *O. taeniolatus* and *O. churahensis*) based on *cyt b*. Together with *O. arnensis*
315 they form the most basal clade (1/100), while the three samples of *O. taeniolatus* from India and
316 Sri Lanka form a distinct clade together with *O. sublineatus* and *Oligodon calamarius* (Linnaeus,
317 1758) also with strong support (1.0/100). This topology renders *O. taeniolatus* sensu lato as
318 paraphyletic. Notably, the sample of *O. taeniolatus* from Sri Lanka is divergent (2.2% p-distance
319 based on 16S rRNA) from the Indian sample, which suggests additional undescribed diversity is
320 present in *O. taeniolatus* outside of Middle and Southwest Asia. Distances of such a percentage
321 based on 16S rRNA are more significant than the *cyt b* gene as 12S–16S rRNA evolves at a
322 slower rate (Mueller, 2006). The newly collected Pakistan sample (CUHC 7904) identified by us
323 as *O. russelius* is recovered within a clade containing two other Pakistan samples from Genbank
324 that were identified as *O. cf. churahensis* by Mirza, Bhardwaj & Patel (2021) with high support
325 (1.0/99). Low genetic divergence ($p = 2.2\%$) exists between the three samples, suggesting they
326 are conspecific. Additionally, the divergence between the Pakistan samples and the type series of
327 *O. churahensis* from Himachal Pradesh, India is only 3.3% in *cyt b* gene (Table 5). The genetic
328 distance between the sample re-identified as *O. cf. tillacki* and samples of *O. arnensis* sensu
329 stricto was also low ($p = 3.6\%$).

330

331 **Species distribution modeling.** The species distribution model (SDM) maps based on
332 geolocation points of *Oligodon* from Iran and Turkmenistan is shown in Figure 3. Variables that
333 mostly account for the species presence are landscape uniformity, mean temperature of coldest
334 quarter (Bio 11), slope, and precipitation seasonality (coefficient of variation) (Bio 15). The
335 average test AUCs for the replicate runs was estimated as 0.988. The predicted distribution of
336 *Oligodon* during past and present epochs expanded and contracted across the Plio-Pleistocene
337 and Holocene and suggests that the current distribution of *Oligodon* in Middle/Southwest Asia is
338 significantly different. The most suitable habitat for *Oligodon* mostly occurred during the last
339 glacial maximum (LGM) period, with the range including more expansive areas of current day
340 Turkmenistan, Afghanistan, and the southern edge of the Caspian Sea. Subsequent range
341 reduction is visible since the mid-Holocene, with the model prediction expecting the most
342 suitable habitat for this species in Köpet-Dag Mountain Range of northeast Iran and southwest
343 Turkmenistan, and small parts of Afghanistan, Azerbaijan, and western Iran (Figure 3).

344

345 **Resurrection and revalidation of *Contia transcaspica* Nikolsky, 1902.** Re-examination of
346 Turkmen and Iranian *O. taeniolatus* as well as past literature descriptions *O. taeniolatus* from
347 this region by Dotsenko (1984) and Latifi (1991) revealed that individuals from these localities
348 are morphologically identical to the type specimen of *Contia transcaspica* (ZISP 9868). These
349 specimens differ from Indian subcontinent *O. taeniolatus* in several features, the most obvious

350 being the presence of only 5 (rarely 6) supralabial scales, and narrow contact between the 4th and
351 5th supralabials due to the bottommost posterior temporal scale. These specimens can also be
352 diagnosed from all members of its sister clade, the *O. arnensis* species group (*O. arnensis*, *O.*
353 *churahensis*, *O. melaneus*, *O. russelius*, and *O. tillacki*), based on several coloration and
354 scalation features, namely the presence of 15 dorsal scale rows throughout the body (*versus* 17–
355 17–15). In terms of color pattern, these specimens also differ from typical *O. taeniolatus* (and
356 most *Oligodon* species across Asia) by the presence of brown transverse crossbars across the
357 dorsal surface. Phylogenetically, the sample of *O. taeniolatus* from northern Iran is monophyletic
358 and separate from all other congeners in the *O. arnensis* species group. Genetic distances
359 between its closest relatives, *O. churahensis*, *O. melaneus*, *O. russelius* are also substantial
360 (5.7%–7.8% based on *cyt b*) are also substantial. Since the combination of molecular and
361 morphological evidence support the distinct status of Iranian and Turkmen *O. taeniolatus*, we
362 resurrect the name *Contia transcaspica* from the subjective junior synonymy of this species. *O.*
363 *taeniolatus* sensu stricto is no longer paraphyletic and is now restricted to the Indian
364 Subcontinent in Bangladesh, India, Sri Lanka, and Pakistan. The Iranian and Turkmen
365 populations from the Köpet–Dag Mountain Range shall now be referred to as *Oligodon*
366 *transcaspicus* **comb. et. stat. nov.** and a detailed redescription, including the holotype of *Contia*
367 *transcaspica*, is provided below.

368

369 ***Oligodon transcaspicus* comb. et stat. nov. (Nikolsky, 1902)**

370 (Figures 4–6; Table 2)

371

372 *Contia transcaspica*: Nikolsky (1902: 839–840). *Holotype*: "Köpet–Dag, Transcaspia" [=
373 now Köpet–Dag Mountain Range, near Ashgabat, Ahal Province, Turkmenistan],
374 Nikolsky (1903a: 11–13), Bobrinskoy (1923: 8), Chernov (1935: 351) (in part), Welch
375 (1983: 77) (in part), Green (2010: 139) (in part), Bandara et al. (2022: 68) (in part), Uetz
376 et al. (2022) (in part)

377 *Oligodon taeniolatus* (in part): Chernov (1935: 351), Filippov (1947), Terentjev & Chernov
378 (1949), Bogdanov (1962), Brück (1968: 201), Nurgeldyev, Shammakov & Atayev (1970:
379 187–190), Rustamov & Atayev (1976: 47–53), Bannikov et al. (1977) Atayev, Gorelov &
380 Shammakov (1978), Szczerbak (1979: 68–70), Welch (1983: 77), Dotsenko (1984: 23–
381 26), Atayev (1985), Szczerbak, Khomustenko & Golubev (1986: 68–70), Latifi (1991: pl.
382 52 & 117), Rustamov & Sopyev (1994: 224), Atayev, Rustamov & Shammakov (1994:
383 337), Szczerbak (1994: 312), Ananjeva et al. (2006: 175), Green (2010: 139), Rustamow
384 (2011), Safaei-Mahroo et al. (2015: 280), Shestopal & Rustamov (2018a: 40), Orlov et al.
385 (2018: 58–67), Rajabizadeh (2018: 242).

386

387 **Holotype.** ZISP 9868, adult female from "Köpet–Dag, Transcaspia" [= now Köpet–Dag
388 Mountain Range, near Ashgabat, Ahal Province, Turkmenistan] collected by N. Kinschin in
389 1901 (Figure 4).

390 **Referred Specimens. Turkmenistan:** Ahal Province. CAS 180042, adult female from
391 “the Iran border south of Goalon, Ashkabad (Ashkhabad) Region” collected in May 1989 by
392 Soviet Border Patrol (obtained by J. R. Macey); ZMMU Re-5589, subadult female from
393 “Karanki”, collected on 1 May 1979; ZMMU Re-6155, juvenile male from “Aidere” unknown
394 collection date; ZMMU Re-7318, adult female from “Chuli, Geok-Tepe” collected on 20 June
395 1990; ZISP 18334, juvenile of undetermined sex from “Geok-Tepe”, collected on May 1971;
396 ZISP 18976, subadult male from “Geok-Tepe”, collected on 05 August 1968. **Iran:** Khorasan
397 Province. ZMMU Re-16687 (field number RAN-3264), adult male from Bazangan Lake, Razavi
398 (36.3044°N, 60.4751°E, WGS 84; 900–950 meters a.s.l.) collected by Roman A. Nazarov and
399 Mehdi Radjabizadeh on 27 May 2017. See Table S1 for more details.

400 **Diagnosis.** A Kukri Snake in the genus *Oligodon* that is distinguished from all other
401 congeners by the following combination of morphological characters: 1) 7–9 maxillary teeth,
402 with posterior two teeth enlarged and blade-like; 2) dorsal scales in 15–15–15 rows; 3) cloacal
403 plate divided; 4) ventral scales 179–188 in males, 193–214 in females; 5) subcaudals 48–52 in
404 males, 44–51 in females; 6) total body scales 232–240 in males, 240–266 in females (232–266
405 scales combined); 7) subcaudal ratio 0.203–0.224 in males, 0.177–192 in females; 8) almost
406 always 5 supralabials (sometimes 6 according to Latifi, 1991), with 3rd supralabial in contact
407 with orbit; 9) loreal and preocular scales present, presubocular sometimes present; 10) posterior
408 temporal scales 3 (rarely 2), with lowest temporal causing 4th and 5th supralabial to contact
409 narrowly; 11) dorsal color pattern beige or light brown with of 42–57 dark transverse crossbands
410 on body and 12–17 crossbands on the tail; 12) dorsal color pattern on tail similar to rest of body,
411 with no vertebral stripe along tail.

412 **Comparisons.** We compare *Oligodon transcaspicus* **comb. et stat. nov.** to all species of
413 *Oligodon* found in Middle and Southwest Asia, which may be confused with this species,
414 particularly *O. taeniolatus* sensu stricto, with which it was previously confused with, and
415 members of its sister clade in the *O. arnensis* species group. We base our comparisons primarily
416 on data from the following literature sources (Wall, 1921; Wall, 1923; Smith, 1943; Khan, 2002;
417 Mirza, Bhardwaj & Patel, 2021; Bandara et al., 2022) as well as data from our own examined
418 specimens (Supplementary Material 1). *Oligodon transcaspicus* **comb. et stat. nov.** can be
419 morphologically assigned to the genus *Oligodon* by having a subcylindrical body, enlarged
420 blade-like maxillary teeth, two prefrontals and internasals present, a blunt and subterminal-
421 shaped rostral scale, length of rostral scale visible from above two times as long as the internasal
422 suture, two temporal scales bordering edge of parietals (generic diagnosis modified from Wall
423 1923).

424 The closest relatives of *O. transcaspicus* **comb. et stat. nov.** include members of the *O.*
425 *arnensis* species group. Of these, *O. transcaspicus* **comb. et stat. nov.** can be distinguished from
426 *O. arnensis* sensu stricto by having 15 dorsal scale rows (*versus* 17–17–15), 179–202 ventrals in
427 both sexes (*versus* 164–188 in both sexes), loreal scale present (*versus* loreal absent), 5–6
428 supralabials (*versus* 7–8, rarely 6), usually 3 posterior temporal scales (*versus* always 2), 7–9
429 maxillary teeth (*versus* 12–16), and irregular dorsal mottling with 47–57 transverse body

430 blotches (*versus* dorsum immaculate, less than 20 black body bands). *O. transcaspicus* **comb. et**
431 **stat. nov.** can be distinguished from *O. churahensis* (later synonymized with *O. russelius*) by
432 having 15 dorsal scale rows (*versus* 17–17–15), 179–202 ventrals in both sexes (*versus* 170–175
433 in both sexes), 5–6 supralabials (*versus* 7–8), usually 3 posterior temporal scales (*versus* always
434 2), and irregular dorsal mottling with 42–57 transverse body blotches 1.5–3.0 dorsal scales wide
435 and 12–16 tail blotches (*versus* 37–45 broad black body crossbars, all edged with a cream color,
436 1.0–2.0 dorsal scales wide and 9–11 tail bars). *O. transcaspicus* **comb. et stat. nov.** is
437 distinguished from *O. melaneus* by having 15 dorsal scale rows (*versus* 17–15–15), 5–6
438 supralabials (*versus* usually 7, rarely 6), usually 3 posterior temporal scales (*versus* always 2),
439 and irregular dorsal mottling with 42–57 transverse body blotches 1.5–3.0 dorsal scales wide and
440 12–16 tail blotches (*versus* black dorsum without conspicuous blotches or markings and a
441 distinct blue ventral coloration in life). *O. transcaspicus* **comb. et stat. nov.** can be distinguished
442 from *O. russelius* by having 15 dorsal scale rows (*versus* 17–17–15), 5–6 supralabials (*versus* 7–
443 8, rarely 6), usually 3 posterior temporal scales (*versus* always 2), and irregular dorsal mottling
444 with 42–57 transverse body blotches 1.5–3.0 dorsal scales wide (*versus* dorsum immaculate with
445 narrow black body bands or crossbars usually edged with white, 1.0–2.0 dorsal scales wide). *O.*
446 *transcaspicus* **comb. et stat. nov.** can be distinguished from *O. tillacki* by having 15 dorsal scale
447 rows (*versus* 17–17–15), 5–6 supralabials (*versus* 7–8), usually 3 posterior temporal scales
448 (*versus* always 2), and irregular dorsal mottling with 42–57 transverse body blotches 1.5–3.0
449 dorsal scales wide (*versus* dorsum immaculate with 25–35 broad black body bands 4.0–6.0
450 dorsal scales wide).

451 In addition, *O. transcaspicus* **comb. et stat. nov.** can be distinguished from *O.*
452 *taeniolatus*, which it was previously confused with, by having 5 (rarely 6) supralabials (*versus*
453 always 7–8) with only the 3rd supralabial contacting the orbit (*versus* usually the 3rd and 4th in
454 contact with orbit), two posterior supralabials (4th and 5th) in narrow contact due to the lowest
455 posterior temporal scale abutting the two scales (*versus* all supralabials in broad contact),
456 temporal scale formula 1+3 (*versus* temporals 1+2), and a dorsal color pattern with irregular
457 transverse crossbars and no distinct vertebral stripe on the body or tail (*versus* dorsal color
458 pattern variable, but usually with irregular non-transverse crossbars or body blotches, and a small
459 thin vertebral stripe on the body and tail).

460 **Redescription of the Holotype (ZISP 9868).** Adult female specimen in good condition
461 after 118 years of preservation. Small portion of midbody in slightly poor condition, large ventral
462 incision posteriorly until vent (Figure 4). SVL 304 mm, TailL 53 mm (TotalL 357 mm). HeadL
463 9.6 mm, HeadW 5.6 mm, SnL 2.6 mm, EyeL 1.4 mm, FrontalL 3.2 mm. TailLR 0.148,
464 HeadW/HeadL 0.58, SnL/HeadL 0.29, EyeL/SnL 0.54, EyeL/HeadL 0.15. Body elongated and
465 cylindrical in cross section; head ovoid, slightly distinct from neck; snout narrowing in dorsal
466 view, depressed very slightly towards the tip with rostral appearing rounded in lateral profile;
467 snout tip subterminal near mouth; eyes moderately sized compared to head, with a round pupil;
468 nostrils small and subelliptical, pointed in lateral view; mouth flat with lips curving upwards
469 posteriorly along last supralabial; tail gradually tapering to a sharp terminal scute.

470 Rostral distinctly enlarged, wider than high, triangular in dorsal view, partially separating
471 the anterior half of internasals; posterior scale suture of rostral with internasals “deep-V” shaped,
472 with vertex of rostral in-line with nostrils as a narrow obtuse angle (~99°); internasals
473 subpentagonal, wider than long, internasal suture equal in length compared to prefrontal suture;
474 prefrontals subhexagonal, wider than long, wider and longer than internasals; frontal
475 subpentagonal, shield shaped, anterior suture with prefrontals concave and angled; frontal longer
476 than prefrontals; eyes placed posterior relative to the anterior edge of the frontal; angle formed
477 by sutures producing the posterior vertex of the frontal a right angle, almost acute (~90°);
478 supraoculars subrectangular, longer than wide, shorter in length than frontal; parietals
479 subpentagonal, longer than wide, width of scale wider than parietal suture, posterior sutures
480 bordering occipital region strongly concave and curved; length of parietals approximately equal
481 in length of frontal; parietal suture shorter than frontal; parietal suture shorter than length of
482 frontal; anterior parietal angle formed by the sutures between the parietal/frontal and the suture
483 between the supraocular/parietal a broad obtuse angle (~130°) with lateral ray of angle pointing
484 posterolaterally. Nasal scale rectangular-shaped, longer than wide, fully divided; loreal 1/1, small
485 and square shaped, slightly wider than than long, less than half the size of the nasal; supralabials
486 5/5; 3rd supralabial in contact with orbit; 5th supralabial largest, first supralabial smallest; all
487 supralabials in broad contact, except for supralabials 4–5, which are in narrow contact due to
488 abutting posterior temporal; preoculars 1/1, wider than long; presubocular 1/1, smaller than
489 preocular; postoculars 2/2, uppermost postocular largest; anterior temporal 1/1; posterior
490 temporals 3/3, bottommost temporal large and subpentagonal in shape, blocking the 4th and 5th
491 supralabial from broadly contacting each other; infralabials 7/7 in all specimens, first in contact
492 with each other, 4/4 infralabials in contact with anterior chin shields; mental subtriangular, wider
493 than long; small mental groove present, starting from border of 1st infralabial and mental
494 terminating at the posterior chin shields; length and width of both chin shields equal in size.

495 Dorsal scale rows 15–15–15, smooth throughout without apical pits; ventral scales 202;
496 subcaudals 47, paired; total body scales 250; subcaudal ratio 0.19; cloacal plate divided; tail tip a
497 sharp pointed scute. Maxillary teeth 7, posterior two teeth enlarged and blade-like.

498 **Coloration in Preservation.** After 121 years in preservation fluids, dorsal ground color
499 cream, margins of some dorsal scales brown forming indistinct and irregular mottling along
500 flanks; 47 indistinct transverse bars along dorsum, broadest vertebrally and slightly narrowing
501 laterally, around 1.5–2.0 dorsal scales at their widest; along tail 12 transverse bands of similar
502 color with any additional markings. Dorsal portion of head is cream, indistinct beige ocular-bar
503 edged with brown starting along 3rd and 4th supralabial scale, past eye covering first half of
504 supraocular, prefrontals and anterior suture of frontal; a second beige and brown-edged temporal
505 bar starting near gulars and first dorsal scales, extending across posterior portion of the fifth
506 supralabial before meeting medially at the parietals and frontal forming a “V” shaped mark;
507 brown nuchal chevron present medially starting at the parietal suture as a small lanceolate tip
508 broadening along the nape as a thick tripartite-shaped blotch, extending laterally on each side of

509 the flanks, ending before reaching the ventral surface. Ventral surface an immaculate cream,
510 faint beige spotting or mottling along edge of ventral scales, more prominent along the tail.

511 **General Description and Variation.** The additional six specimens examined agree with
512 the description of the holotype in most aspects of coloration, scalation and morphometric
513 characteristics. SVL 145–312 mm in male, 267–361 mm in females; TailL 27–70 mm in male,
514 42–64 mm in females; TotalL in male 195–382 mm, 309–425 mm in females. The largest
515 specimen is an adult female (ZMMU Re-7318) with a SVL of 361 mm and TailL of 64 mm.
516 HeadL 5.9–9.6 mm; HeadW 3.6–6.0 mm, SnL 2.3–3.5 mm, EyeL 0.8–1.4 mm, FrontalL 1.4–3.2
517 mm. TailLR 0.157–0.183 in males, 0.136–0.159 in females, HeadL/HeadW 0.53–0.72,
518 SnL/HeadL 0.27–0.42, EyeL/SnL 0.34–0.54, EyeL/HeadL 0.12–0.15. Body elongated and
519 cylindrical, slightly robust along midbody in some specimens; head ovoid, slightly distinct from
520 neck; snout narrowing in dorsal view, depressed only slightly towards the tip in dorsolateral
521 view; head oblong in lateral profile; snout tip subterminal near mouth; eyes moderately sized
522 compared to head; nostrils pointed in lateral view; mouth flat, lips slightly curved posteriorly;
523 tail tapering to a sharp terminal scute.

524 Rostral distinctly enlarged, wider than high, triangular in dorsal view, extending
525 posteriorly partially separating internasals; posterior scale suture of rostral with internasals
526 “deep-V” shaped, with vertex of rostral in-line with nostrils obtuse angled (95° – 115°); internasals
527 subpentagonal, wider than long, suture roughly equal or slightly longer than prefrontal suture;
528 prefrontals subhexagonal, wider than long, longer and wider than internasals; frontal
529 subhexagonal, shield shaped, anterior margin of scale clearly angled in most specimens but
530 sometimes more concave; the posterior border of the frontal of one specimen (ZMMU Re-
531 16687) is slightly notched with two pores near the border of the parietals and two similar notched
532 “pores” in the center of the scale (Figure 5); frontal around twice the length of prefrontals;
533 supraoculars subrectangular, longer than wide, shorter in length and width than frontal; eyes
534 placed posterior relative to the anterior edge of the frontal; angle formed by sutures producing
535 the posterior vertex of the frontal right or acute-angled (80° – 90°); oftentimes the posterior
536 portion of the frontal truncates, giving the vertex a notched appearance in dorsal profile; parietals
537 subpentagonal, posterior portion concave and usually curved, occasionally straight; parietals
538 slightly longer than wide, width of scale wider than parietal suture; length of parietals equal or
539 slightly longer than length of frontal; parietal suture shorter than frontal length; anterior parietal
540 angle formed by the sutures between the parietal/frontal and the suture between the
541 supraocular/parietal a broad obtuse angle (120° – 130°) with lateral ray of angle pointing
542 posterolaterally. Nasal scale rectangular to square shaped, fully divided and usually longer than
543 wide; loreal 1/1, square-shaped, around a quarter or half the size of nasal; supralabials 5/5 in all
544 examined specimens, although Latifi (1991) mentions specimens with 6 supralabials; 3rd
545 supralabial always in contact with orbit; 5th supralabial largest, 1st supralabial smallest; all
546 supralabials in broad contact, except for supralabials 4–5, which contact narrowly due to abutting
547 posterior temporal; preoculars 1/1, uppermost preocular slightly larger; presubocular 1/1 present
548 in four specimens (including holotype), absent in rest; postoculars 2/2, uppermost postocular

549 largest; anterior temporal 1/1; posterior temporals 3/3 (in one specimen, CAS 180042, 3/2),
550 bottommost temporal large and subpentagonal in shape, blocking the 4th and 5th supralabial from
551 broadly contacting each other; infralabials 7/7 in all specimens, first in contact with each other,
552 4/4 infralabials in contact with anterior chin shields; mental subtriangular, wider than long; small
553 mental groove present, starting from border of 1st infralabial and mental terminating at the
554 posterior chin shields; length and width of both chin shields equal in size.

555 Dorsal scale rows 15–15–15, smooth throughout and without apical pits; ventral scales
556 179–188 in males, 193–202 in females; subcaudals 48–52 in male, 44–51 in females; total body
557 scales 232–240 in male, 240–266 in females; subcaudal ratio 0.203–0.224 in males, 0.177–192 in
558 females; anal plate divided; tail tip tapers to a sharp tip. Maxillary teeth 7 in two specimens
559 (including the holotype) and 9 in one specimen (CAS 180042), posterior two teeth enlarged and
560 blade-like. Teeth unavailable for examination in other specimens. We did not examine the
561 hemipenis of any specimens as all organs were retracted. The structure of hemipenes is a rather
562 conservative feature. Therefore, despite the lack of any information about hemipenial
563 morphology of *O. transcaspicus* **comb. et stat. nov.**, we expect that the fully everted and
564 expanded hemipenes of this species will likely share the same structure with its closest relatives
565 in the *O. arnensis* species group, namely a short and slightly bilobed hemipenes with spinous
566 calyces and a simple sulcus spermaticus. Our sample size is too low to make statistical
567 comparisons between sexes, however a few instances of putative sexual dimorphism are noted.
568 First, the number of ventral scales appear to be higher in the single male specimen. The male
569 specimens also have a higher number of subcaudals, TailLR ratio and subcaudal ratio than the
570 females. The number of total body scales appears to be higher in females.

571 All specimens in preservative have a cream to beige colored dorsum, with brown
572 mottling mostly well-defined and restricted across the flanks, some vertebral portions of dorsum
573 also with white mottling; 47–57 transverse crossbars, usually light brown with the margins of
574 dorsal scales along bars dark-brown or black and the edges of each bar surrounded weakly edged
575 by white; all crossbars more well-defined compared to the holotype, widest in the vertebral
576 region and are narrower laterally, at widest between 1.5–3.0 dorsal scales in length; crossbar
577 counts on body are not sexually dimorphic; tail blotches range from 12–16 and are similar in
578 coloration. Dorsal surface of the head tan to cream, lower portions of snout sometimes grayish-
579 brown; occasional vermiculations present along supralabials and underside of head; the position
580 of the ocular and temporal bars are consistent amongst all specimens, but are usually brown or
581 dark-brown and edged with black; the nuchal chevron in some specimens is lanceolate-shaped at
582 its anterior origin along the parietals, but in two specimens it is blunt or obtuse-pointed,
583 terminating before the ventral surface along the nape as a thick tripartite or triangular-shaped
584 blotch. No vertebral stripe is present along the tail in preserved specimens. The ventral surface is
585 tan to cream, with three specimens bearing irregular margins of dorsal cross-bands visible on
586 lateral sides of the ventral scales, but in other specimens the ventral surface is immaculate. The
587 color in life based on ZMMU Re-16687 (Figure 5) and two specimens photographed in
588 Turkmenistan by A. V. Pavlenko (Figure 6) resembles the coloration in preservative, but its

589 dorsal patterning and blotching are more pronounced. In these specimens, the dorsum is brown to
590 reddish-brown with white mottling concentrated on the vertebral region and white and dark-
591 brown mottling concentrated on the flanks; the transverse bars are brown and have small dark-
592 brown edges on the dorsal scales of each bar; the nuchal chevron and ocular bars are darker than
593 the bars on the dorsum; iris of eyes gold-brown, pupils black; ventral surface and areas between
594 head markings plain white.

595 **Distribution and Natural History.** The known distribution of *Oligodon transcaspicus*
596 **comb. et stat. nov.** is summarized in Figure 1 and Table S1. This species is currently known
597 from the Köpet–Dag region of northern Iran and southern Turkmenistan. In Turkmenistan, it is
598 known from the present-day Balkan, Ahal and Mary provinces. The distribution of the species in
599 Turkmenistan was recently reviewed by Orlov et al. (2018). They report *O. transcaspicus* **comb.**
600 **et stat. nov.** from ten localities in the foothills of the Köpet–Dag Mountains: Balkan and Ahal
601 Provinces (Danata spring; Eldere Gorge north from Kara–Kala; Chandyr Valley; Makhmumkala
602 village; Kara–Elchi and Eishem gorges; Aidere, Kurygol; Arvaz Valley; 7 km northwards from
603 Saivan; Firuza and Chuli villages; Shamly, near Babazo) and from two localities in Mary
604 Province (Dana–Germab spring, and Nardyvanly spring; environs of Badkhyz). In Iran,
605 *Oligodon transcaspicus* **comb. et stat. nov.** is known definitively from Razavi Khorasan
606 Province from two localities (ZMMU Re-16687 from Bazangan Lake; and another sight record
607 we confirm from ~5 km SW of Mashhad), and Golestan Province (town of Dashliburun [Dashil
608 Borun]). The Golestan Province records originates from Latifi (1991), who reported the locality
609 as “Mazandaran Province (Ghonbad Kavooos) ... in Dashley Boron region”. At the time of
610 Latifi’s writings, the locality “Ghonbad Kavooos... Dashley Boron” (the romanized spelling of
611 Gonbad-e Kavus county) was included within Mazandaran Province before being separated into
612 Golestan Province in 1997. We here confirm this locality in Golestan Province as “Dashliburun”
613 (sometimes spelled as “Dashil Boron”), close to the Turkmenistan border. Rajabizadeh (2018)
614 reported the species in Northeastern Iran close to border of Turkmenistan from eastern Golestan
615 Province to north of Khorasan Razavi Province. Latifi (2000) and Safaei-Mahroo et al. (2015)
616 also reported this species from North Khorasan, and from Zanjan and West Azarbaijan
617 Provinces, although the occurrences in western Iran require further verification (see Discussion).

618 The natural history of *Oligodon transcaspicus* **comb. et stat. nov.** is somewhat well-
619 known in the literature (Dotsenko, 1984; Atayev, 1985; Szczerbak, Khomustencko & Golubev,
620 1986; Rustamov & Sopyev, 1994; Szczerbak, 1994; Atayev, Rustamov & Shammakov, 1994;
621 Orlov et al., 2018) and several additional specimens have been recorded. Two specimens
622 photographed by A. Pavlenko (pers. comm.) were found in the daytime amongst rocky outcrops
623 (Figure 6); however, Orlov et al. (2018) noted most specimens were strictly nocturnal or
624 crepuscular. These authors found *Oligodon transcaspicus* **comb. et stat. nov.** was most abundant
625 between elevations of 400–700 meters, but also noted a few specimens that were found at lower
626 and higher altitudes. Most animals were captured at the base of gradually sloping mountain
627 gorges, riverbeds and open habitats with shrubs and tree vegetation that maintain enough surface
628 moisture. Based on this, Orlov et al. (2018) posited that the activity period of *Oligodon*

629 *transcaspicus* **comb. et stat. nov.** is highly dependent on high moisture and relative humidity
630 and will only come up on the surface when these conditions are met. Like other *Oligodon*, this
631 species probably feeds on reptile and bird eggs. Atayev, Rustamov & Shammakov (1994) and
632 sources therein record this species laying one to two eggs between the months of May and June,
633 suggesting the reproductive season is in the spring and early summer. It is assumed like other
634 *Oligodon* that its diet primarily consists of reptile eggs.

635 **Remarks.** Most sources that mention *O. transcaspicus* **comb. et stat. nov.** have cited
636 Nikolsky (1903a) as the source of original description. However, we have discovered an earlier
637 book that was also authored by Nikolsky describing *Contia transcaspica* dated to 1902. Thus, the
638 year of original description and its publication source should be fixed, and we do so here in the
639 present paper.

640 **Etymology.** The species epithet “*transcaspicus*” is a latinized toponymic adjective in
641 genitive singular and given in reference to the type locality of this species, which during the time
642 of its description, was called the Transcaspian Region (Zakaspiyskaya Oblast or Zakaspiyskiy
643 Krai) and was part of the Turkestan Governor–Generalship of the Russian Empire. The
644 Transcaspian Region later became known as Turkmenistan during its time as a constituent
645 republic of the Soviet Union (Turkmen S.S.R.) and now as an independent nation. The epithet is
646 fixed to agree with the gender of the generic name *Oligodon*, which is masculine. We
647 recommend the English common name “Köpet–Dag Kukri Snake” for this species, followed by
648 the Russian, Farsi, and Turkmen common names “Zakaspiyskiy oligodon”, “دَاغ کپه مار لوس”
649 [*Loos Mār-e Kopet Dagh*], and “Goňurja ýylanjyk”, respectively (see Rustamow, 2011;
650 Rajabizadeh, 2018).

651
652 **The taxonomic status of *Oligodon “arnensis”* in Pakistan.** Because the revision of *O. arnensis*
653 *sensu auctorum* by Bandara et al. (2022) only focused on material from India and Sri Lanka, we
654 use this section to review the status of these snakes in neighboring Pakistan. We examined one
655 specimen of *O. “arnensis”* (CUHC 7904) recently collected by DJ and RM on 16 September
656 2018 from Kallar Kahar, Punjab Province, Pakistan (32.7695°N, 72.7065°E, 613 m a.s.l.). Based
657 on the presented mtDNA phylogeny, this specimen was recovered in a clade with two additional
658 samples from Pakistan that were previously identified as *O. cf. churahensis* by Mirza, Bhardwaj
659 & Patel (2021). These authors only briefly commented on the status of these genetic samples and
660 could not examine voucher specimens from Pakistan in their study. A brief description of CUHC
661 7904 is as follows (Figure 7): adult male, SVL 345 mm, TailL 65 mm (TotalL 410 mm; TailLR
662 0.159) 16–17–15 dorsal scale rows, 183 ventrals, 49 subcaudals (233 total body scales),
663 subcaudal ratio of 0.21, 1/1 loreal present, 1/1 divided nasal, 7/7 supralabials with the third and
664 fourth in contact with the eye, 7/7 infralabials, and an immaculate brown dorsum with 37 black
665 crossbands across the body and 13 tail bands approximately 1.0–1.5 dorsal scales wide at
666 midbody and interspaces between each band approximately 4.0 dorsal scales long. In addition to
667 this specimen, multiple authors who have conducted fieldwork in Pakistan (Minton, 1962;
668 Minton, 1966; Mertens, 1969; Khan, 2002) have recorded *O. “arnensis”* specimens. Both

669 Minton (1962) and Khan (2002) figure an *O. "arnensis"* (with Khan, 2002 swapping the images
670 of *O. "arnensis"* and *O. taeniolatus* by mistake) bearing small narrow black crossbars with white
671 edges. Based on these characteristics, along with other scalation features (see Table 3), the
672 literature descriptions of Pakistani *O. "arnensis"* are very similar to CUHC 7904 and specimens
673 *O. russelius* fide Bandara et al. (2022). Therefore, based on our specimen and previous reports of
674 *O. "arnensis"*, we refer the northern Pakistan populations of *O. "arnensis"* to *O. russelius*.

675

676 **Records of *Oligodon* in Afghanistan.** Literature reports of *O. "arnensis"* and *O. taeniolatus*
677 from Afghanistan are sparse but have been the subject of confusion for decades. Brück (1968)
678 first reported a juvenile Kukri Snake he identified as *O. taeniolatus* from “dem Gebiete um
679 Djelalabad” [= vicinity of Jalalabad]. This record was plotted by Sindaco et al. (2013) but
680 rejected due to imprecision by Wagner et al. (2016b). Although Brück (1968) identified this
681 specimen as *O. taeniolatus*, data he provided for this specimen indicates it bears 17 dorsal scale
682 rows, contra the 15 dorsal scales normally observed in *O. taeniolatus*. This was noticed quickly
683 by Král (1969), who subsequently corrected its identification to *O. arnensis*. Nevertheless, both
684 Sindaco, Venchi & Grieco (2013) and Wagner et al. (2016b) recorded both *O. arnensis* and *O.*
685 *taeniolatus* as inhabitants of Afghanistan, failing to realize that their records refer to the same
686 specimen (MMB 28497). Brück (1968)’s account provided additional morphological data that
687 allow us to confirm its identification. He notes that the specimen bears the following features:
688 juvenile (unsexed, but based on relative tail length and subcaudal ratio, possibly an immature
689 female), SVL 153 mm, TailL 24 mm (TotalL 177 mm, TailLR 0.136), dorsal scales in 17 rows,
690 198 ventrals, 44 subcaudals, (243 total body scales, subcaudal ratio 0.181), 7/7 supralabials (3–5
691 contacting eye), 6/6 infralabials, 1 preocular, 2 postocular, 1+2 temporals, and 49 dark crossbars
692 across the body and tail. These characteristics confirm that the specimen should not be identified
693 as *O. taeniolatus* and that Král’s re-identification as *O. "arnensis"* was correct (see Table 3 for
694 more comparisons). A second *Oligodon* record from Afghanistan was recently documented on
695 the citizen science platform iNaturalist (2022). This specimen (obs. 110932106, user
696 mohammadfarooq) was observed from Dara-i-Pech district, Kunar Province, Afghanistan
697 (35.0553°N, 70.9561°E; 1,700–1,800 meters a.s.l.) on 9 April 2022. While photographs of the
698 specimen are too poor in quality to discern any scalation features, its color pattern consisting of
699 approximately 51 black crossbars and 13 tail bars (64 total crossbars) greatly resembles *O.*
700 *"arnensis"*, specifically *O. russelius* (and to some extends *O. churahensis* but see Discussion).
701 Because of this, we conclude that the Afghanistan populations previously recorded as *O.*
702 *arnensis* (Khan, 2002; Wagner et al., 2016b) should also represent *O. russelius*. All records of
703 this species from the country are restricted to the western portion of the Hindu Kush.

704 The only other report of an Afghan *Oligodon* is a record of *O. taeniolatus* from
705 Afghanistan noted by Wagner et al. (2016b) from “Kars, Kandahar Province” based on specimen
706 USNM 194971. We attempted to trace the voucher of this specimen and discovered that the
707 museum catalog number USNM 194971 refers to a scincid lizard *Eurylepis taeniolatus* Blyth,
708 1854a, and not a kukri snake. No collection records of *Oligodon* from Afghanistan have been

709 found within the USNM collections ledger (E. Langan, 2022, pers. comm.), and so we consider
710 the Kandahar Province record of *O. taeniolatus* to be erroneous. The similar species epithets
711 between *E. taeniolatus* and *O. taeniolatus* may have caused Wagner et al. (2016b) to mistake its
712 identity, resulting in a *lapsus calami*. Therefore, we formally remove *O. taeniolatus* from the
713 herpetofauna of Afghanistan, Iran, and Turkmenistan. However, we note that the presence of *O.*
714 *transcaspicus* **comb. et stat. nov.** in Afghanistan is still possible, particularly in northwestern
715 provinces bordering with Iran and Turkmenistan (suggested also by the SDM analysis).

716 Discussion

717 The phylogenetic analysis of 12S–16S rRNA, *cyt b* fragments, morphological data and
718 SDM mapping data support the resurrection of *Contia transcaspica* as *Oligodon transcaspicus*
719 **comb. et stat. nov.** for Iranian and Turkmen populations previously ranked under *O. taeniolatus*.
720 This analysis also revealed substantial genetic differentiation between populations of *O.*
721 *taeniolatus* on the Indian subcontinent warranting additional revisionary work from future
722 authors. We cannot provide a valid description for the deeply divergent lineages in Sri Lanka and
723 mainland India due to a lack of broad morphological and genetic sampling. However, we note
724 that the names *Oligodon fasciatus* Günther, 1864 (now considered a subspecies of *O.*
725 *taeniolatus*) and *Oligodon taeniolatus* var. *ceylonicus* Wall, 1921 are both available names for
726 Sri Lankan populations if they indeed prove to be distinct from others on the island, and/or the
727 remainder of the Indian subcontinent. While the taxonomy of *O. taeniolatus* remains unresolved,
728 the position of *O. transcaspicus* **comb. et stat. nov.** outside of this clade in the *O. arnensis*
729 species group justifies its separation as a distinct species. The distribution of *O. transcaspicus*
730 **comb. et stat. nov.** is probably more expansive than currently ascertained, and we expect that
731 this species will eventually be found in additional localities across the Köpet–Dag Mountain
732 region.

733 The SDM models identified some patches of suitable habitat across the Western Caspian region
734 and Central Iranian Desert in areas where Latifi (1991, 2000) and Safaei-Mahroo et al. (2015)
735 reported its presence. Unfortunately, we could not trace any specimen vouchers of Latifi's
736 collection in the Razi Vaccine and Serum Research Institute associated with these Iranian
737 records. Since these Latifi's specimens come from snake hunters of the institute (and were not
738 collected by Latifi himself) and the locality data is given only at province level, researchers must
739 be very cautious about them. Only subsequent fieldwork in these areas might verify such reports,
740 particularly in adjacent Iranian provinces bordering Turkmenistan.

741 Verified vouchers specimens of *O. transcaspicus* **comb. et stat. nov.** also exist close to the
742 border of Afghanistan in Mary Province, Turkmenistan. Since SDM modelling also predicts
743 suitable habitat in this region, it is possible that this species also persists in the northwestern
744 portion of Afghanistan (specifically Herat, Badghis, Faryab and Jowzan provinces), but a lack of
745 survey effort due to security concerns makes it difficult to ascertain whether this species will be
746 found here anytime soon (see Jablonski et al., 2021). The conservation of *O. transcaspicus*
747 **comb. et stat. nov.** does not seem to be under any significant threats, although factors such as
748 habitat degradation and human encroachment could pose a threat to some populations. Climate

749 projections also state that aridification and a reduction of river runoff is expected across the
750 southern portion of Turkmenistan over the following decades (Lioubimtseva et al., 2012; Duan et
751 al., 2019). Because the SDM mapping analyses indicated temperature and precipitation
752 seasonality were major factors influencing the distribution of *O. transcaspicus* **comb. et stat.**
753 **nov.**, climate change may also negatively impact populations. Under listings provided by the
754 International Union for Conservation of Nature (IUCN) we would recommend classifying this
755 species as “Least Concern”. Continued monitoring of existing populations and additional field
756 surveys across the Köpet–Dag Mountain Range would improve our understanding of the ecology
757 and conservation of this species.

758 Although our sampling is very limited, the results from our study suggest the three-taxon
759 statement of the *O. arnensis* sensu auctorum by Bandara et al. (2022) requires additional
760 scrutiny. Specimens we included from Ganjam district, Odisha, India (CAS 17224–225) are well
761 within the distribution of *O. russelius* (fide Bandara et al., 2022) and both morphologically
762 resemble *O. arnensis* sensu stricto, bearing 18–20 dark black body bands that are 2.0–3.0 dorsal
763 scales wide. Another specimen collected near Rajamahendravaram, Andhra Province, India
764 (CAS 94375) is close to the type locality of *O. russelius* but has 22 dorsal body bands that are
765 1.5–2.0 dorsal scales wide (band count resembling the species diagnosis of *O. arnensis* sensu
766 stricto fide Bandara et al., 2022). Either the ranges of *O. arnensis* sensu stricto and *O. russelius*
767 are sympatric in parts eastern India, or a broad contact zone between the two species may exist.
768 This could explain why some specimens we examined have more variable color pattern
769 conditions than previously described. The distribution map of *O. arnensis*, *O. russelius* and *O.*
770 *tillacki* in Bandara et al. (2022)’s clearly separates the three taxa on the Indian subcontinent;
771 however, we note that the collection localities in their map combine collection localities with
772 observations identified from iNaturalist. We agree that such citizen scientist databases have great
773 utility in documenting rare and understudied herpetofauna, but they still can suffer from data
774 quality issues (i.e., limited number of visible morphological features, misidentification errors). It
775 is difficult to discern which locations in Bandara et al. (2022)’s map are voucher specimens or
776 iNaturalist observations because the authors do not provide a geolocation appendix in their paper
777 and do not denote a distinction between their location datapoints. Furthermore, we note that the
778 p-distance (based on *cyt b*) between Sri Lankan *O. arnensis* samples and the GenBank sample
779 identified as *O. cf. tillacki* is only 3.6%, lower than most normal p-distances separating species-
780 level lineages of *Oligodon*. We conservatively retain the species status of *O. tillacki* as we have
781 not directly examined the voucher specimen of this sample to verify its identity. Subsequent
782 treatments of *O. arnensis* sensu stricto, *O. russelius*, and *O. tillacki* should emphasize increased
783 specimen and tissue collection for an integrative taxonomic approach.

784 Our analysis also confirmed the taxonomic identity of *O. “arnensis”* populations in
785 northern Pakistan and Afghanistan as *O. russelius*. Nevertheless, several authors (Minton, 1966;
786 Mertens, 1969; Khan, 2002) note the distribution of *O. “arnensis”* extends into central and
787 southern Pakistan close to the border of western India. These locations come close to the known
788 distribution of *O. tillacki*, especially near Gujarat State, India. However, Minton (1966) noted

789 that all his specimens have black bars with white edges, a phenotypic trait that Khan (2002) also
790 described. Both illustrations by these authors show a “V-shaped” marking on the nape, although
791 it is not a thick triangular blotch that is observed in *O. tillacki*. We believe there is little
792 indication that *O. “arnensis”* populations in southern and central Pakistan match the description
793 *O. tillacki* and we maintain the identity these populations as *O. russelius* for the time being. It is
794 still possible that *O. tillacki* could range into this part of the country due to the continuity of
795 habitat within this region, and we suggest future herpetological survey work and the examination
796 of additional material to confirm this. Such a discovery could align with recent studies that have
797 denoted a biogeographic break between the right and left banks of the Indus River seen in several
798 Pakistani amphibians and reptiles (Gowande et al., 2021; Agarwal et al., 2022; Dufresnes et al.,
799 2022).

800 Our study has taxonomic implications for the recently described *O. churahensis*, as
801 Mirza, Bhardwaj & Patel (2021) tentatively associated Pakistani samples of *O. “arnensis”* with
802 this species. Like the genetic distances between *O. cf. tillacki* and *O. arnensis* sensu stricto, the
803 *cyt b* p-distance between the Pakistani clade of *O. russelius* (= *O. cf. churahensis*) and the clade
804 containing the type series of *O. churahensis* is low for species-level divergence, standing at only
805 3.3%. *Oligodon churahensis* was described by Mirza, Bhardwaj & Patel (2021) based on two
806 specimens collected at the foothills of the western Himalayas in Himachal Pradesh, India.
807 Bandara et al. (2022) correctly noted that literature descriptions of kukri snakes similar to *O.*
808 *churahensis* were reported as *O. arnensis* sensu lato (= now *O. russelius*) by past authors (Wall,
809 1921; Deraniyagala, 1936; Constable, 1949; Deraniyagala, 1955). However, because Bandara et
810 al. (2022) include data from these historical sources into their conception of *O. churahensis* (as
811 seen in their supplementary material), diagnosing this species from *O. russelius* becomes
812 puzzling. In the comparisons section of *O. russelius*, Bandara et al. (2022) separated this species
813 from *O. churahensis* by the presence of 30–45 crossbars (*versus* 48–54 in *O. churahensis*) the
814 distance between each crossbar measured in vertebral dorsal scales (4–6 scales *versus* 2–4 in *O.*
815 *churahensis*), and by a different head shape marking (inverted Y-shaped marking *versus* heart-
816 shaped symbol in *O. churahensis*). However, the authors note that *O. churahensis* has 56–62
817 crossbars in the remaining text, especially in Table 1, where it is again compared to the 30–45
818 crossbars of *O. russelius*. It appears that the authors confused the true number of crossbars found
819 in *O. churahensis* and *O. russelius*, failed to specify between “total crossbars” (including body
820 and tail bars) and “body crossbars” (restricted from nape to vent) and did not completely
821 summarize the color pattern traits observed in all of the sources they believe comprise *O.*
822 *churahensis* (Wall, 1921; Deraniyagala, 1936; Constable, 1949; Deraniyagala, 1955; Mirza,
823 Bhardwaj & Patel 2021). Per the original description (Mirza, Bhardwaj & Patel 2021), the actual
824 number of body crossbars in *O. churahensis* is 37–45, with the total crossbars noted as 48–54.
825 Furthermore, Bandara et al. (2022) state in the written description that *O. russelius* has 30–45
826 body crossbars and 6–10 tail bars. This indicates that the supposed differences in crossbar
827 numbers are a lot less significant than previously considered. As argued by Mahony & Kamei

828 (2021), errors and inconsistencies in taxonomic articles are inevitable, but authors should
829 practice great care to make sure data inputted into descriptions and tables is consistent.

830 When we combine our own data on *O. russelius* from Afghanistan, Pakistan with the
831 clarified characters of Bandara et al. (2022) and existing data in the literature (Wall, 1921;
832 Constable, 1949), most color pattern and scalation traits between this taxon and *O. churahensis*
833 overlap (Table 3). Combined with the low genetic divergence revealed by our molecular data,
834 our study does not support the species-rank status of *O. churahensis*. It is plausible that
835 specimens identified as *O. churahensis* represent the high-end of a geographic cline of cross-
836 banded phenotypes found within *O. russelius* across its range, as suggested in part by Wall
837 (1921). Alternatively, it is possible that the *O. churahensis* and *O. russelius* clades could
838 maintain their reciprocal monophyly, albeit with low genetic divergence that would support the
839 existence of two lineages at the subspecies level. In the absence of additional samples from the
840 type locality of *O. churahensis* and adjacent regions of northern India and Pakistan, we believe
841 the most appropriate decision is to relegate the species to the junior synonymy of *O. russelius*,
842 which we do so here.

843 Our resurrection of *O. transcaspicus* **comb. et stat. nov.** and the clarification of *O.*
844 “*arnensis*” and *O. taeniolatus* records from Middle and Southwest Asia represents a small step of
845 a long journey in our goal of understanding the evolutionary history of snakes and other
846 herpetofauna of this region. Interestingly, several reptiles found in Middle and Southwest Asian
847 countries that are Oriental realm elements of the region’s herpetofauna are recognized as
848 separate taxa. Such examples include *Boiga trigonata melanocephala* (Annandale, 1904),
849 *Lycodon striatus bicolor* Nikolsky, 1903b and *Ptyas mucosa nigriceps* Terentjev & Chernov,
850 1949. Other reptile taxa found in Middle/Southwest Asia whose close relatives are of Oriental
851 realm origin include *Naja oxiana* Eichwald, 1831 and *Eublepharis macularius* Blyth, 1854b. For
852 these latter species, phylogeographic evidence indicates minimal genetic differentiation between
853 populations opposite of the Hindu Kush suggesting rapid range expansion from the Indian
854 subcontinent into Middle/Southwest Asia due to suitable environmental conditions formed by
855 steppe habitats west of the Hindu Kush mountains (Kazemi et al., 2021; Agarwal et al., 2022).
856 The uniqueness of the evolutionary lineage representing *O. transcaspicus* **comb. et stat. nov.**
857 paints a different picture, as the presented molecular, morphological and SDM evidence implies
858 that the divergence of its common ancestor into present-day Iran and Turkmenistan occurred
859 much earlier. The high topography surrounding the Hindu Kush and the south-adjacent Registan-
860 North Pakistan sandy deserts present formidable biogeographic barriers, and probably limited
861 dispersal opportunities periods when climatic and habitat conditions were suitable. The diversity
862 and cladogenesis of other Oriental-affiliated elements of Middle and Southwest Asia’s
863 amphibians and reptiles are still poorly understood by herpetologists, and present numerous
864 intriguing questions for future research. The acquisition of new material along with more
865 comprehensive phylogeographic analyses will undoubtedly shed light on these unique animals
866 and their taxonomic and evolutionary status.

867 **Conclusions**

868 We carefully reviewed the status of the two kukri snake species found in Middle and
869 Southwestern Asia, the banded kukri snake *O. "arnensis"* and the streaked kukri snake *O.*
870 *taeniolatus*, leading to several taxonomic and distributional clarifications. For *O. taeniolatus*, we
871 found that specimens from the Köpet-Dag Mountain Range of northern Iran and southern
872 Turkmenistan were phylogenetically recovered in a different intrageneric grouping compared to
873 nominotypical *O. taeniolatus* on the Indian subcontinent. To fix this paraphyly, we resurrected
874 the junior synonym *Contia transcaspica* and provided a thorough morphological redescription
875 supplemented with SDM mapping to explore its potential range. We also found that Afghanistan
876 and northern Pakistan records of kukri snakes previously recognized as *O. arnensis* should in
877 fact be allocated to the species *O. russelius*. This latter species forms a clade sister to the recently
878 described *O. churahensis* from northern India, but is only separated by a small genetic
879 divergence of 3.3% based on cytochrome *b*. Because the morphology between *O. russelius* and
880 *O. churahensis* exhibits substantial overlap, we consider both species to be conspecific, and
881 relegate *O. churahensis* to junior synonymy. Our investigation further revealed that there are no
882 records of *O. taeniolatus* from Afghanistan, as the two past reports from the literature refer to a
883 misidentified specimen of *O. russelius*, and a misidentified scincid lizard, respectively. As a
884 consequence, we remove *O. taeniolatus* from the snake fauna of Afghanistan, Iran, and
885 Turkmenistan. The two kukri snakes found in Middle and Southwestern Asia now consist of
886 *transcaspicus* **comb. et stat. nov.** and *O. russelius*. These two species represent key Oriental
887 herpetofaunal elements in a region that primarily consists of Palearctic amphibians and reptiles.
888 Their ranges in Middle and Southwest Asia appear to be influenced by past climate change
889 across the Hindu Kush Mountain range, in addition to past biotic and abiotic fluctuations that
890 occurred during the Plio-Pleistocene. Future studies that explore the biogeographic origins of
891 these animals are recommended. We also suggest that additional taxonomic work on *O. arnensis*
892 and *O. taeniolatus* are needed on Indian subcontinent populations. The number of recognized
893 species in *Oligodon* remains at 89.

894 **Acknowledgements**

895 Permission to conduct fieldwork in Iran was granted by the International Center for Science,
896 High Technology and Environmental Sciences, Kerman, Iran (contract number 1.87, issued at
897 11.04.2008), in Sri Lanka by the Department of Wildlife Conservation and Department of Forest
898 Conservation (WL/3/2/1/14/12), and in Pakistan by the permit of the Pakistan Museum of
899 Natural History, Islamabad, Pakistan (No. PMNH/EST-1[89]/05). We are also grateful to
900 Alexander V. Pavlenko for providing photographs and detailed locality information of two *O.*
901 *transcaspicus* **comb. et stat. nov.** he observed in the field. We thank the following curators,
902 collections managers and other staff members for permission to examine specimens under their
903 care and assistance with laboratory materials and protocols: Lauren Scheinberg, Erica Ely, Jens
904 Vindum, and Alan Leviton (CAS); Jana Poláková (Comenius University in Bratislava); and Roy
905 W. McDiarmid, Steve Gotte, Jeremy Jacobs, Kenneth Tighe, Addison Wynn, and George R. Zug

906 (USNM); Valentina F. Orlova, Evgeniy A. Dunayev, Evgeniya Shepelya, and Evgeniya N.
907 Solovyeva (ZMMU); Natalia B. Ananjeva and Igor Doronin (ZISP). We are indebted to
908 (reviewers) for their constructive comments on this manuscript. JLL thanks Aaron M. Bauer
909 (Villanova University, USA) for providing important copies of literature and additional support.
910 JLL was partially supported by the University of Maryland College of Computer, Mathematical
911 and Natural Sciences and the Ernest Cory Undergraduate Scholarship during the earlier
912 development of this manuscript. SK would like to thank Dr. Ansem de Silva and Dr. Kanishka
913 Ukuwela for various help for permission to use parts of his data. We also thanks to Pouria
914 Sardari for providing a specimen from northeastern Iran. PD'S and AKM wish to thank Kartik
915 Shankar for laboratory assistance. The research was completed within the frameworks of Russian
916 State projects A16116021660077-3, 122031100282-2 and AAAA-A17-117030310017-8.
917

918 **ADDITIONAL INFORMATION AND DECLARATIONS**

919

920 **Funding**

921 Specimen storage and examination was completed with financial support of Russian Science
922 Foundation (RSF grant No. 22-14-00037; molecular phylogenetic analysis, specimen
923 examination) to NAP; with partial support of the Russian Foundation for Basic Research and
924 Iran National Science Foundation (Grant no. 20-54-56033; specimen collection) to RAN; and
925 by the grant of the Scientific Grant Agency of the Slovak Republic VEGA 1/0242/21 (SDM
926 modeling, specimen collection) to DJ. The funders had no role in study design, data collection
927 and analysis, decision to publish, or preparation of the manuscript.
928

929

929 **Grant Disclosures**

930 The following grant information was disclosed by the authors:
931 Russian Science Foundation: 22-14-00037
932 Russian Foundation for Basic Research and Iran National Science Foundation: 20-54-56033
933 Scientific Grant Agency of the Slovak Republic: VEGA 1/0242/21
934

935

935 **Competing Interests**

936 Nikolay A. Poyarkov serves as an Academic Editor for PeerJ. The other authors declare that they
937 have no competing interests.
938

939

939 **Author Contributions**

940 **Justin L. Lee** collected data, conceived and designed the experiments, analyzed the data,
941 prepared figures and tables, prepared the drafts of the paper, reviewed drafts of the paper, and
942 approved the final draft.

943 **Platon V. Yushchenko** collected data, conceived and designed the experiments, analyzed the
944 data, prepared figures and tables, prepared the drafts of the paper, reviewed drafts of the paper,
945 and approved the final draft.

946 **Konstantin D. Milto** collected data, prepared figures, reviewed drafts of the paper, discussion of
947 the results

948 **Mehdi Radjabizadeh** collected data, prepared figures, reviewed drafts of the paper, discussion
949 of the results

950 **Eskandar Rastegar Pouyani** analyzed the data, reviewed drafts of the paper, discussion of the
951 results

952 **Daniel Jablonski** collected data, contributed analysis tools, prepared figures, prepared the drafts
953 of the paper, reviewed drafts of the paper, and approved the final draft, discussion of the results

954 **Rafaqat Masroor** collected data for the paper, contributed analysis tools, reviewed drafts of the
955 paper, approved the final draft, discussion of the results

956 **Suranjan Karunarathna** collected data for the paper, contributed analysis tools, reviewed
957 drafts of the paper, approved the final draft, discussion of the results

958 **Ashok Kumar Mallik** analyzed the data, contributed analysis tools, reviewed drafts of the
959 paper, discussion of the results

960 **Princia Dsouza** collected data for the paper, reviewed drafts of the paper, approved the final
961 draft, discussion of the results

962 **Nikolai L. Orlov** analyzed the data, reviewed drafts of the paper, discussion of the results

963 **Roman A. Nazarov** collected data, prepared figures, reviewed drafts of the paper, discussion of
964 the results

965 **Nikolay A. Poyarkov** conceived and designed the experiments, analyzed the data, prepared the
966 drafts of the paper, reviewed drafts of the paper, and approved the final draft.

967

968 **Animal Ethics**

969 The following information was supplied relating to ethical approvals (i.e., approving body and
970 any reference numbers):

971 Specimen collection protocols and animal operations followed the Institutional Ethical
972 Committee of International Center for Science, High Technology and Environmental Sciences,
973 Kerman, Iran (Certificate #1.87-1).

974

975 **Field Study Permissions**

976 The following information was supplied relating to field study approvals (i.e., approving
977 body and any reference numbers):

978 Field works, including collection of the samples and animals in the field, was performed outside
979 of any protected area, in the framework of a project contract signed by International Center for
980 Science, High Technology and Environmental Sciences, Kerman, Iran (contract number 1.87,
981 issued at 11.04.2008). The contract bears a permission to collect the reptile samples outside of
982 any protected area of Department of the Environment (specified in www.doe.ir) that needed

983 extra permissions. Specimen collection protocols and animal operations followed the
984 Institutional Ethical Committee of International Center for Science, High Technology and
985 Environmental Sciences, Kerman, Iran (certificate number 1.87-1).

986

987 **DNA Deposition**

988 The following information was supplied regarding the deposition of DNA sequences:
989 Sequences of 12S–16S rRNA and *cyt b* genes presented here are accessible via GenBank
990 accession numbers OQ092426; OQ099833–OQ099837; and OQ116816–OQ116825 (Table 1).

991

992 **Data Availability**

993 The following information was supplied regarding data availability:
994 Specimens examined in this study are deposited in herpetological collections of the following
995 museums:

- 996 1. CAS: California Academy of Sciences, San Francisco, USA;
- 997 2. CUHC: Comenius University Herpetological Collection, Bratislava, Slovakia;
- 998 3. MMB: Department of Zoology, Moravian Museum, Brno, Czech Republic;
- 999 4. USNM: National Museum of Natural History, Washington, DC, USA;
- 1000 5. ZISP: Zoological Institute of Russian Academy of Sciences, St. Petersburg, Russia;
- 1001 6. ZMMU: Zoological Museum of Moscow State University, Moscow, Russia.

1409 Supplementary Material and Table Legends:

1410

1411 **Supplementary Material 1.** Other Specimens of *Oligodon* examined, organized based on their
1412 morphological identification based on Bandara et al. (2022).

1413

1414 **Supplementary Table 1.** Tabled list of localities of *Oligodon transcaspicus* **comb. et stat. nov.**
1415 with latitude and longitude coordinates used for species distribution modelling.

1416

1417 **Supplementary Table 2.** Primers used in this study

1418

1419 Table Legends:

1420

1421 **Table 1. Sequences and voucher specimens of *Oligodon* and outgroup taxa used in**
1422 **molecular analyses of this study.**

1423 Note that the numbers (column one) included in this table are not the same as those found in
1424 other tables or figures. Acronyms present here that are not noted in the materials and methods
1425 include the following: CHS, unknown field tag series; KIZ, Kunming Institute of Zoology,
1426 Chinese Academy of Sciences, Kunming, China; NCBS, National Center for Biological
1427 Sciences, Bangalore, India; RAP, field tags of R. Alexander Pyron; ROM, Royal Ontario
1428 Museum, Toronto, Canada; RS, field tags of Ruchira Somaweera; SIEZC, Department of
1429 Zoology, Southern Institute of Ecology, Ho Chi Minh City, Vietnam; SYNU, Shenyang Normal
1430 University, Shenyang, China; TNHC, Texas Natural History Collections, Austin, USA; UMMZ,
1431 University of Michigan Museum of Zoology, Ann Arbor, USA; ZMUVAS, Zoological Museum
1432 of the University of Veterinary and Animal Sciences, Punjab, Pakistan. Additional abbreviations
1433 include NP: National Park, NR: Nature Reserve, and WS: Wildlife Sanctuary.

1434

1435 **Table 2. Selected morphological characters of *Oligodon transcaspicus* comb. et stat. nov.**
1436 **based on examined specimens.**

1437 Abbreviations for males and females are denoted by (m) or (f) respectively. For abbreviations of
1438 characters, see materials and methods section for details.

1439

1440 **Table 3. Morphological comparisons of *Oligodon russelii* specimens from Afghanistan,**
1441 **northern India, and Pakistan hitherto recognized as *Oligodon “arnensis”* or *Oligodon***
1442 ***churahensis*.**

1443 Data from the literature are combined from multiple authors unless denoted with an asterisk (*),
1444 which indicates that only a single source was used. Abbreviations for males and females are
1445 denoted by (m) or (f) respectively and (total) is used to indicate that the data combines both
1446 sexes or combines the total number of body and tail blotches.

1447

1448 **Table 4. Pairwise matrix of genetic distances between and within *Oligodon* species sampled**
1449 **in this study.**

1450 Uncorrected p-distances (given as percentages) are based on sequences of the cytochrome *b*
1451 mtDNA gene are shown below the diagonal. Intraspecific genetic p-distances are shown along
1452 the diagonal and are highlighted in bold. See Table 1 for the list of samples used to create this
1453 matrix.

1454

1455 Figure Legends:

1456

1457 **Figure 1. Approximate distribution and location of samples utilized in this study for**
1458 **molecular and morphological analyses (A); and approximate distribution of *Oligodon***
1459 ***transcaspicus* comb. et stat. nov in the Köpet–Dag Mountain range of Iran and**
1460 **Turkmenistan (B).**

1461 Triangle icons denote specimens with only molecular data; square icons denote specimens with
1462 only morphological data; rhombic icons denote specimens without molecular and morphological
1463 data (only locality is known); round icons denote specimens with both molecular and
1464 morphological data. Stars/asterisks next to numbers indicate type localities. Localities: (1)
1465 Ashgabat, Ahal Prov., Turkmenistan (type locality of *Oligodon transcaspicus* **comb. et stat.**
1466 **nov**); (2) Chuli, Ahal Prov., Turkmenistan; (3) Geok-Tepe, Ahal Prov., Turkmenistan; (4)
1467 Karanki, Ahal Prov., Turkmenistan; (5) “Goalon” (Goudan), Ahal Prov., Turkmenistan; (6)
1468 Aidere, Ahal Prov., Turkmenistan; (7) Bazangan Lake, Razavi Khorasan Prov., Iran; (8) Punjab
1469 Prov., Pakistan; (9) Kallar Kahar, Punjab Prov., Pakistan; (10) Chamba Distr., Himachal
1470 Pradesh, India (type locality of *Oligodon churahensis*); (11) Jalalabad, Nangarhar Prov.,
1471 Afghanistan; (12) Dara-i-Pech district, Kunar Prov., Afghanistan; (13) Maharashtra, India; (14)
1472 Chitwan NP, Bagmati Prov., Nepal; (15) Ganjam, Odisha, India; (16) 24.1 km SW of
1473 Rajamahendravaram, Andhra Pradesh, India; (17) Bangalore, Karnataka, India; (18) Tamil Nadu,
1474 India; (19) Puttalam Distr., North Western Prov., Sri Lanka; (20) Udawalawe National Park, Uva
1475 Prov.; (21) Monargala Distr., Southern Prov., Sri Lanka; (22) Hambantota Distr., Southern Prov.,
1476 Sri Lanka; (23) Gampaha Distr., Western Prov., Sri Lanka; (24) Polonnaruwa Distr., North
1477 Central Prov., Sri Lanka; (25) Paramikulam, Kerala, India; (26) Barengabari, Assam, India.

1478

1479 **Figure 2. Phylogenetic tree of *Oligodon* derived from the analysis of 3,019 bp of 12S rRNA,**
1480 **16S rRNA and *cyt b* mitochondrial DNA gene sequences.**

1481 For voucher specimen information and GenBank accession numbers see Table 1. Numbers at
1482 tree nodes correspond to BI PP/ML BS support values, respectively; n-dash denotes no support.
1483 Outgroup taxa are not shown. Colors of clades and locality numbers correspond to Figure 1.

1484

1485 **Figure 3. Species distribution model (SDM) map based on geolocation points of *Oligodon***
1486 ***transcaspicus* comb. et stat. nov. from Iran and Turkmenistan.**

1487 Darker red coloration indicates more suitable habitat, whereas lighter colors indicate less suitable
1488 habitat.

1489

1490 **Figure 4. Photographs of the preserved holotype specimen of *Contia transcaspica* (ZISP**
1491 **9868) now *Oligodon transcaspicus* comb. et stat. nov. from “Köpet–Dag, Transcaspica”.**

1492 Scale bars equal 10 millimeters. Photos by Konstantin D. Milto.

1493

1494 **Figure 5. Live photographs of *Oligodon transcaspicus* comb. et stat. nov. (ZMMU Re-**
1495 **16687; field number RAN-3264) from Khorasan Province, Iran.**

1496 (a) Right lateral, (b) left lateral, (c) ventral, (d) ventral views of the head, and (e) general habitus.
1497 Photographs by Roman A. Nazarov.

1498

1499 **Figure 6. Two unvouchered specimens of *Oligodon transcaspicus* comb. et stat. nov.**

1500 Specimens photographed from (a) Podere, Sumbar Valley, Turkmenistan and (b) Seqiz-Khan
1501 Gorge, Turkmenistan. Photographs taken by Alexander V. Pavlenko.

1502

1503 **Figure 7. Photographs of *Oligodon russelius* from Pakistan (a–e) and Afghanistan (f).**

1504 Shown in a–e is specimen CUHC 7904 from Kallar Kahar, Punjab Province, Pakistan, showing
1505 (a) general habitus in life, (b) right lateral, (c) left lateral, (d) dorsal, and (e) ventral views of the
1506 head in preservative. Shown in (f) is a cropped image of *O. russelius* from Kunar Province,
1507 Afghanistan observed on iNaturalist (obs. 110932106, user mohammadfarooq). Photographs a–e
1508 by Daniel Jablonski, photograph f taken by Mohammad Farooq from iNaturalist.org.

Figure 1

Figure 1. Approximate distribution and location of samples utilized in this study for molecular and morphological analyses (A); and approximate distribution of *Oligodon transcaspicus* comb. et stat. nov in the Köpet-Dag Mountain range of Iran and Tur

Triangle icons denote specimens with only molecular data; square icons denote specimens with only morphological data; rhombic icons denote specimens without molecular and morphological data (only locality is known); round icons denote specimens with both molecular and morphological data. Stars/asterisks next to numbers indicate type localities. Localities: (1) Ashgabat, Ahal Prov., Turkmenistan (type locality of *Oligodon transcaspicus* **comb. et stat. nov**); (2) Chuli, Ahal Prov., Turkmenistan; (3) Geok-Tepe, Ahal Prov., Turkmenistan; (4) Karanki, Ahal Prov., Turkmenistan; (5) "Goalon" (Goudan), Ahal Prov., Turkmenistan; (6) Aidere, Ahal Prov., Turkmenistan; (7) Bazangan Lake, Razavi Khorasan Prov., Iran; (8) Punjab Prov., Pakistan; (9) Kallar Kahar, Punjab Prov., Pakistan; (10) Chamba Distr., Himachal Pradesh, India (type locality of *Oligodon churahensis*); (11) Jalalabad, Nangarhar Prov., Afghanistan; (12) Dara-i-Pech district, Kunar Prov., Afghanistan; (13) Maharashtra, India; (14) Chitwan NP, Bagmati Prov., Nepal; (15) Ganjam, Odisha, India; (16) 24.1 km SW of Rajamahendravaram, Andhra Pradesh, India; (17) Bangalore, Karnataka, India; (18) Tamil Nadu, India; (19) Puttalam Distr., North Western Prov., Sri Lanka; (20) Udawalawe National Park, Uva Prov.; (21) Monargala Distr., Southern Prov., Sri Lanka; (22) Hambantota Distr., Southern Prov., Sri Lanka; (23) Gampaha Distr., Western Prov., Sri Lanka; (24) Polonnaruwa Distr., North Central Prov., Sri Lanka; (25) Paramikulam, Kerala, India; (26) Barengabari, Assam, India.

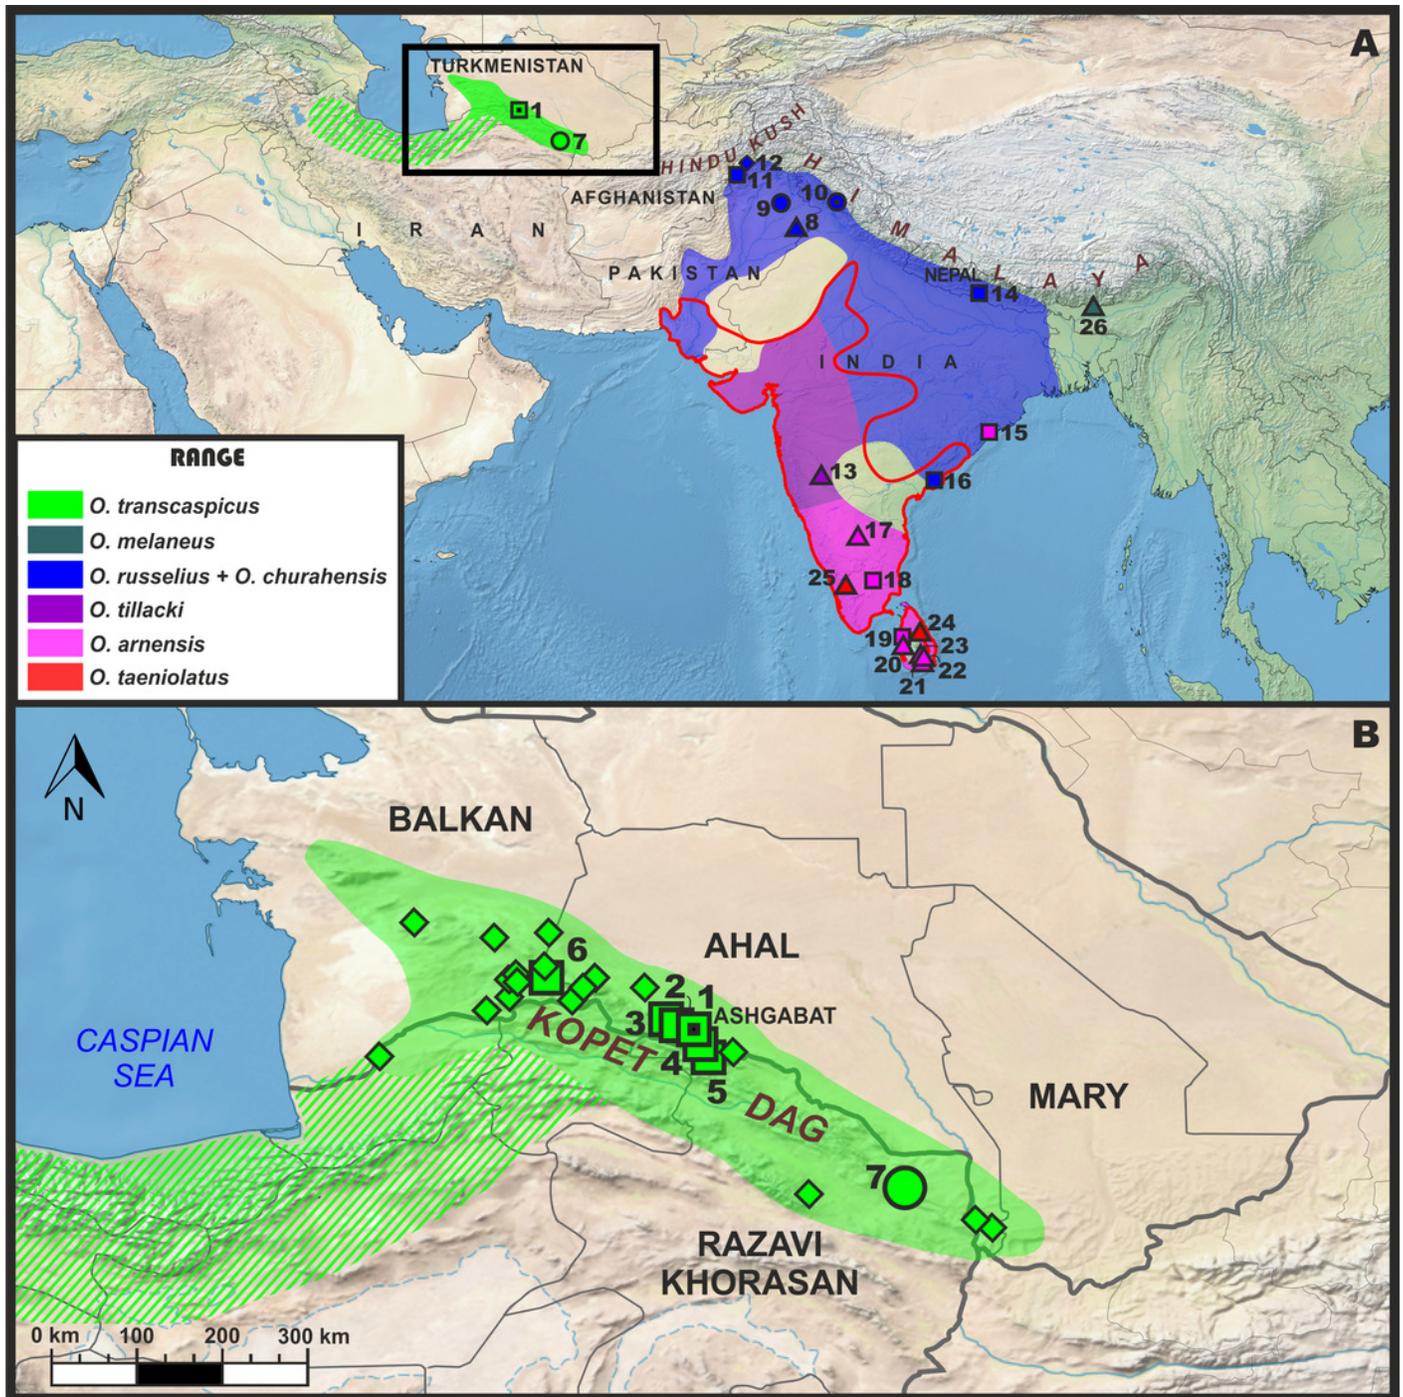

Figure 2

Figure 2. Phylogenetic tree of *Oligodon* derived from the analysis of 3,019 bp of 12S rRNA, 16S rRNA and cyt *b* mitochondrial DNA gene sequences.

For voucher specimen information and GenBank accession numbers see Table 1. Numbers at tree nodes correspond to BI PP/ML BS support values, respectively; n-dash denotes no support. Outgroup taxa are not shown. Colors of clades and locality numbers correspond to Figure 1.

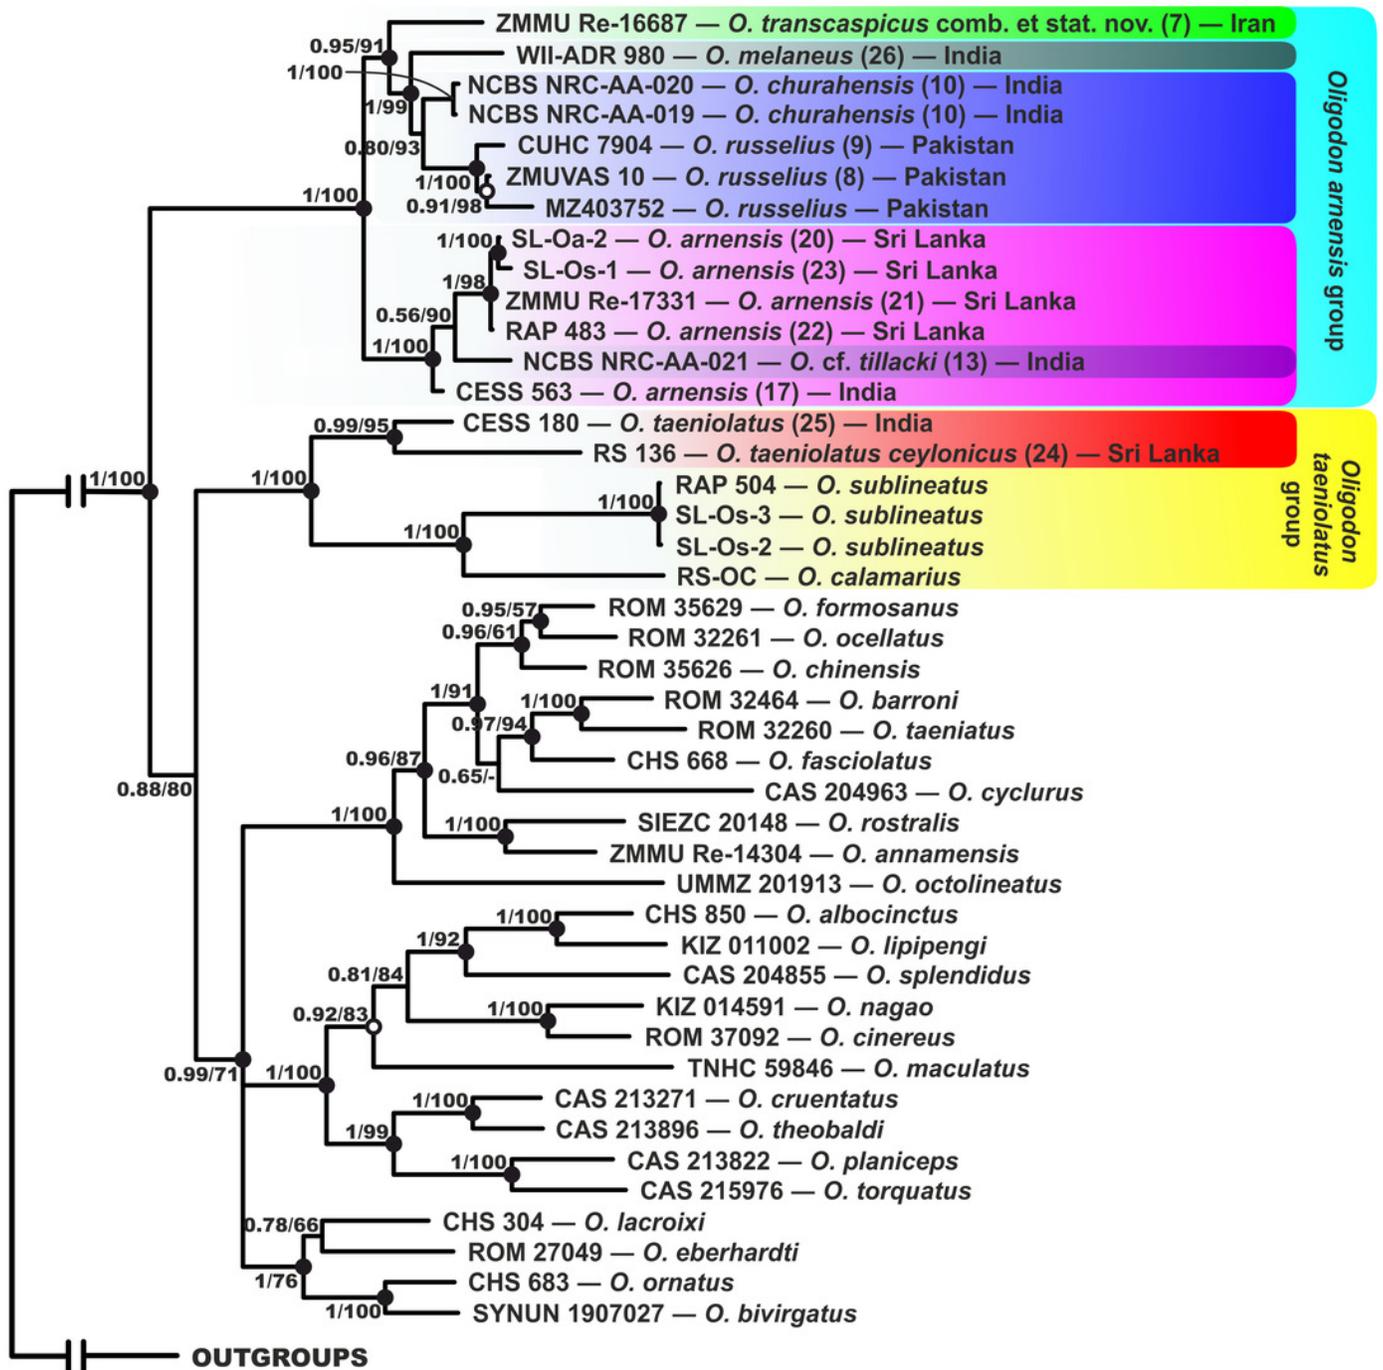

Figure 3

Figure 3. Species distribution model (SDM) map based on geolocation points of *Oligodon transcaspicus* comb. et stat. nov. from Iran and Turkmenistan.

Darker red coloration indicates more suitable habitat, whereas lighter colors indicate less suitable habitat.

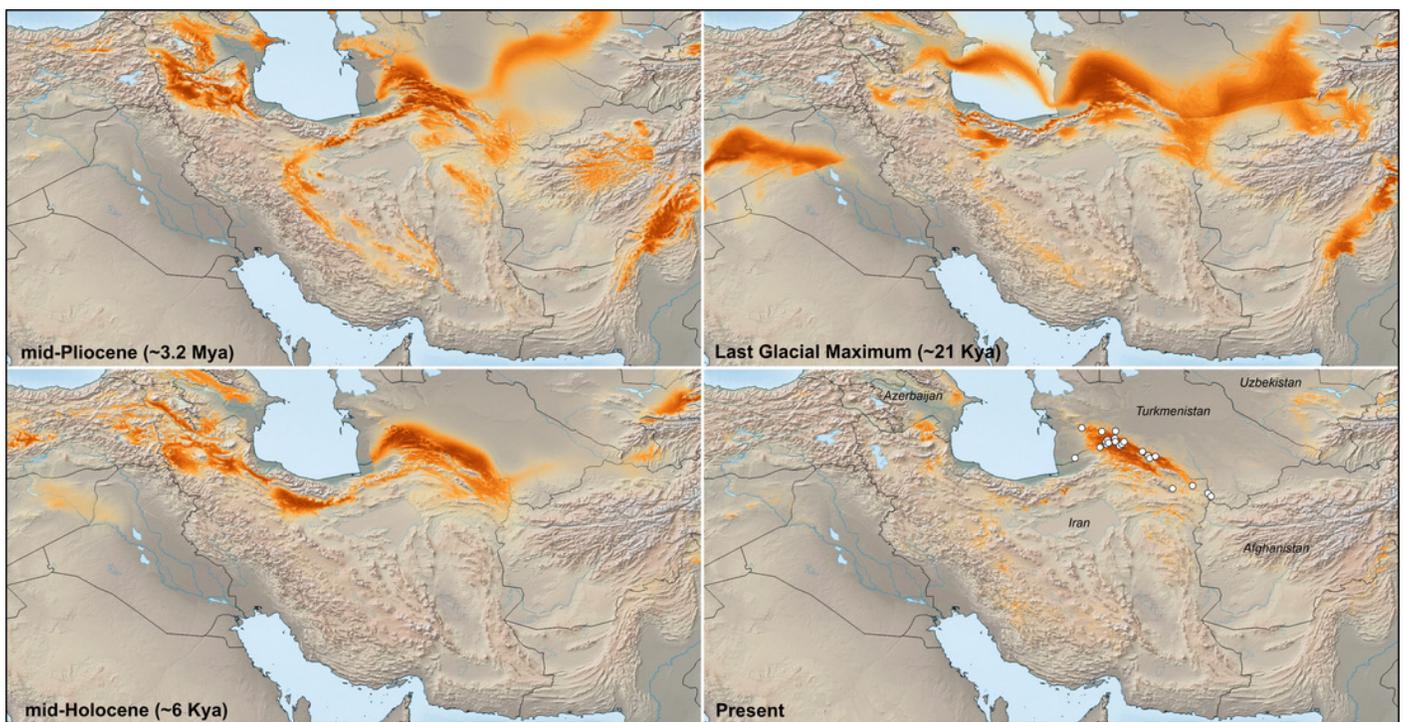

Figure 4

Figure 4. Photographs of the preserved holotype specimen of *Contia transcaspica* (ZISP 9868) now *Oligodon transcaspicus* comb. et stat. nov. from “Köpet-Dag, Transcaspica”.

Scale bars equal 10 millimeters. Photos by Konstantin D. Milto.

Figure 5

Figure 5. Live photographs of *Oligodon transcaspicus* comb. et stat. nov. (ZMMU Re-16687; field number RAN-3264) from Khorasan Province, Iran.

(a) Right lateral, (b) left lateral, (c) ventral, (d) ventral views of the head, and (e) general habitus. Photographs by Roman A. Nazarov.

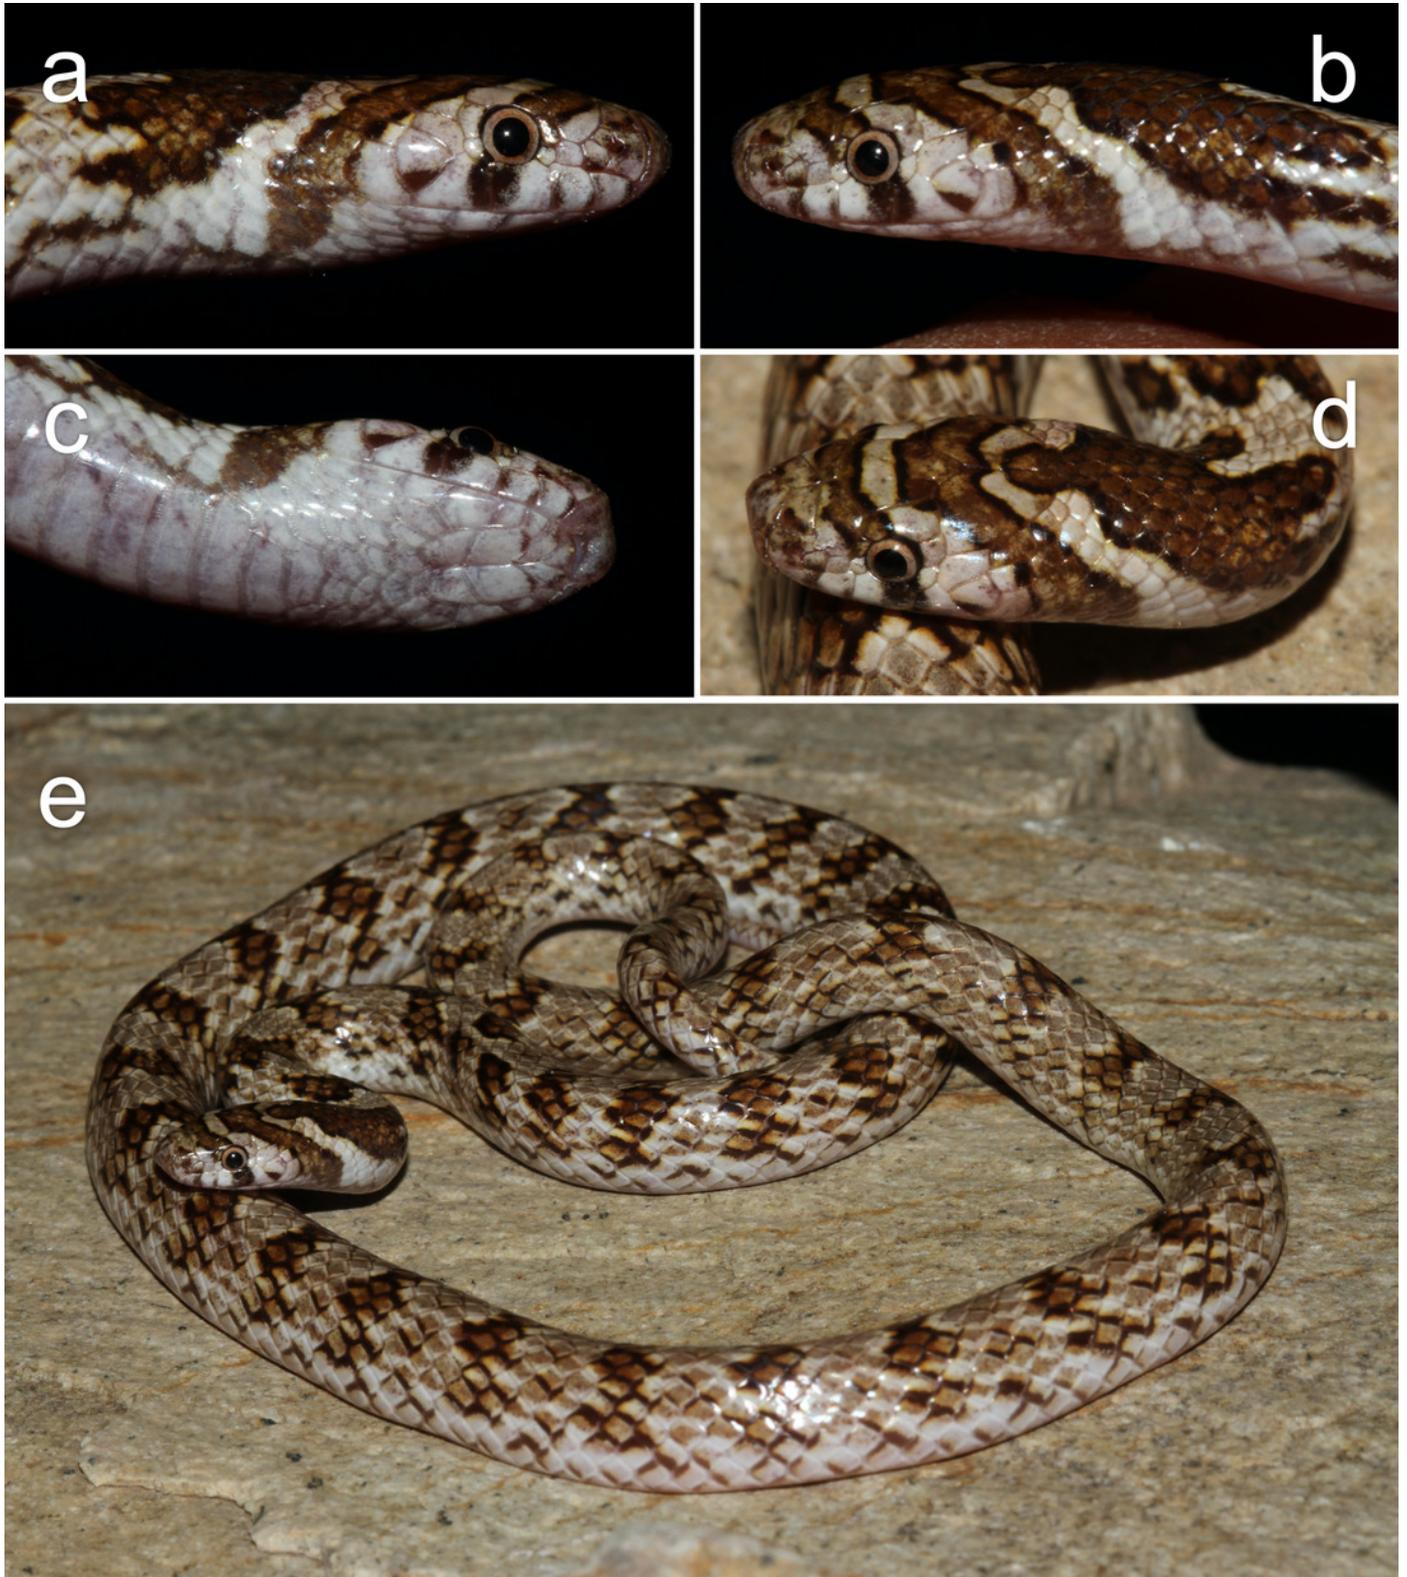

Figure 6

Figure 6. Two unvouchered specimens of *Oligodon transcaspicus* comb. et stat. nov.

Specimens photographed from (a) Podere, Sumbar Valley, Turkmenistan and (b) Seqiz-Khan Gorge, Turkmenistan. Photographs taken by Alexander V. Pavlenko.

Figure 7
