ABSTRACT

As an important farmed fish, tilapia has poor tolerance to low-temperatures. At the same time, different tilapia strains have apparent differences in low-temperature tolerance. In this study, using the iTRAQ method, the phosphorylated proteomics of two tilapia strains (*Oreochromis niloticus* and *Oreochromis aureus*) with different tolerances to low-temperature stress were quantitatively and comparatively analyzed, to clarify the physiological mechanism of tilapia's response to low-temperature stress. Through the GO and IPR analyses of differentially phosphorylated proteins, a number of similarities in physiological activities and regulatory effects were found between the two tilapias in response to low-temperature stress. Many differentially phosphorylated proteins are mainly involved in lipid metabolism, cell proliferation and apoptosis. However, the difference in endurance of low temperature of these two tilapias might be related to the differences in categories, expression and modification level of genetic products which were involved in the aforementioned physiological processes. And meanwhile, the enrichment results of KEGG showed the changes of multiple immune-related and growth-related phosphorylated proteins in the cytokine-cytokine receptor interaction pathway in *O. aureus* are more prominent. Furthermore, the significantly enriched pathway of carbohydrate digestion and absorption in *O. niloticus* may indicate that low-temperature stress exerts a more severe impact on energy metabolism. The relative results would help elucidating the molecular mechanism by which tilapia responds to low-temperature stress, and developing culture of tilapia species.

INTRODUCTION

Tilapia (*Oreochromis spp.*), native to Africa, belongs to Cichlidae of the Perciformes. As an important and the third largest cultured fish in the world, tilapia has been widely cultivated in tropical and subtropical areas. As a warm-water fish, tilapia has a growth temperature range of 16–38 °C and a suitable temperature range of 26–29 °C, with poor

low-temperature tolerance (Wohlfarth & Hulata, 1981). Its sensitivity to low-temperature environments often leads to slow growth and even mass death. Low temperature can affect tilapia's metabolism, immune function, cell cycle and other life activities (Dellagostin et al., 2022; Velmurugan, Chan & Weng, 2019; Yilmaz et al., 2021). When the temperature is below 15 °C, the body of tilapia will be damaged, and the semi-lethal low temperature is about 10 °C (Cnaani, Gall & Hulata, 2000; Li et al., 2002; Tave, 1990). In recent years, extreme weather has occurred more frequently, which has a significant impact on the tilapia aquaculture industry. As a result, a large amount of effort has been required to ensure the safe overwintering of tilapia. Its poor low-temperature tolerance has always been one of the bottlenecks restricting the development of the tilapia industry; how to improve the low-temperature tolerance has become one of the critical problems facing the further development of its aquaculture industry. At present, the main cultivation species of tilapia include blue tilapia (*Oreochromis aureus*), Nile tilapia (*Oreochromis niloticus*), Mozambique tilapia (*Oreochromis mossambicus*) and various hybrid species. The growth capacity, disease resistance and low-temperature resistance of various tilapia species significantly differ. For example, in a comparative feeding experiment on different tilapia species, *O. niloticus* was shown to possess superior growth rates and feed conversion rate (Day, Salie & Stander, 2016). In addition, tilapia galilea had an innate advantage against *Streptococcus agalactiae* infection when compared with Nile tilapia NEW GIFT strain and Nile tilapia JA strain (Huang et al., 2013). The semi-lethal low temperature of *O. aureus* was 7.82–8.44 °C, and that of *O. niloticus* was 9.39–10.13 °C (Charo-Karisa et al., 2005; Cnaani, Gall & Hulata, 2000; Nobrega et al., 2020). Therefore, it is of great significance to study the differences in the low-temperature tolerance of tilapia strains for the selection and breeding of tilapia varieties with low temperature tolerance.

Post-translational modifications (PTMs) are covalent chemical modifications of amino acids after translation, thereby changing the properties of proteins (Uversky, 2013). It is an important reason why living organisms can carry out complex physiological processes under the condition of a limited number of genes (Mann & Jensen, 2003). Phosphorylation modification is one of the most important post-translational modification methods of proteins. It is the reversible process of transferring a phosphate group on ATP or GTP to the amino acid residue of the substrate protein under the action of protein kinase, involving almost all physiological processes of the body (Cohen, 1982; Iakoucheva et al., 2004; Nirujogi et al., 2015). In eukaryotic organisms, one-third of the proteins are phosphorylated at any time (Ficarro et al., 2002). In recent years, the omics technology has been widely applied to study protein phosphorylation modification, covering various research areas, including physiology, stress resistance, drug research and environmental research (Babur et al., 2020; Huang et al., 2018; Wang et al., 2020). Therefore, the analysis of post-translational modification of tilapia's proteome is of great potential to further understand its response mechanism to low-temperature stress.

As a protein quantitative technology, iTRAQ (isobaric tags for relative or absolute quantitation) can simultaneously analyze up to 8–10 samples of proteins, and is a commonly used high-throughput screening technology in proteomics (He et al., 2019). At present, it has been widely used in the research of phosphorylated proteome. Accordingly, this

technology should be more than adequate to reveal the effect of low-temperature on protein phosphorylation modification of tilapia. As an important digestive, metabolic, detoxifying and immune organ of fish, the liver would undergo important changes when fish were exposed to low temperature stress ([Chen et al., 2022](#); [Jiao et al., 2020](#); [Wang et al., 2022b](#)). Hence, two tilapias (*O. aureus* and *O. niloticus*) with different low-temperature resistance were selected as target species, and comparative study on the changes of protein phosphorylation modification in the liver of these two species under low-temperature stress was performed. The results could provide basic information on the response mechanism of tilapia to low-temperature stress at the molecular level, and help improving the low-temperature tolerance of tilapia.

MATERIALS & METHODS

The care, handling, and sampling of fish were performed following animal care protocols approved by the Laboratory Animal Centre of Yangtze River Fisheries Research Institute, Chinese Academy of Fishery Sciences.

Experimental fish and experimental method

O. aureus and *O. niloticus* were obtained from the Freshwater Fisheries Research Center of Chinese Academy of Fisheries Sciences (Wuxi, Jiangsu, China) and transported to the Yangtze River Fisheries Research Institute (Wuhan, Hubei, China).

The initial body weight and length of *O. aureus* and *O. niloticus* were 20.09 ± 2.76 g and 19.61 ± 2.86 g, 7.69 ± 1.02 cm and 7.56 ± 0.94 cm, respectively. Before commencing experiments, the fish were domesticated for two weeks at 30 °C in an indoor recirculating aquaculture system with 20 fish per 450-L polyethylene cultivation tanks. After that, a refrigerator was used to reduce the water temperature from 30 °C to 10 °C by 1 °C per day. Fish were hand-fed to apparent satiation or cessation of feeding three times daily (08:30, 12:30 and 16:40). Normal feeding was maintained during the cooling period and the low-temperature stress experiment. The dissolved oxygen was detected daily. The other water quality parameters were monitored in the morning once a week. The water pH was 7.2–7.5, the dissolved oxygen was higher than 5.0 mg/L, and the total ammonia nitrogen was lower than 0.5 mg/L during the culture phase. The formulation of the diet in this experiment was show in [Table S1](#).

Sample preparation

After the tilapias were respectively kept at 30 °C and 10 °C for 24 h, liver samples were collected. A total of sixteen *O. niloticus* were collected at 10 and 30 °C, anesthetized with tricaine methane sulfonate solution (100 mg/L) (MS-222, GREENHX Biological Technology Co. Ltd., Beijing, China). And then the fish were dissected on ice, the liver was quickly isolated and placed in a two mL cryopreservation tube at –80 °C for proteomic analysis. More specifically, the liver of eight *O. niloticus* collected from four tanks (two fish per tank) were sampled at 30 °C, and each four liver samples were mixed to form two single pools for the iTRAQ experiment. Similarly, another two liver sample pools were also collected at 10 °C. *O. aureus* samples were collected in the same way as for *O. niloticus*.

Protein extraction and trypsin digestion

The liver sample was ground into powder in liquid nitrogen and transferred to a centrifuge tube. The ice-cold lysis buffer (7 M urea, 2 M thiourea, 4% SDS, 40 mM Tris-HCl, pH 8.5, 1 mM PMSF, and 2 mM EDTA) was added to liver samples and maintained at 4 °C for 5 min; then, DTT was added to reach a final concentration of 10 mM. The lysed samples were centrifuged at 15,000×g for 30 min at 4 °C to remove cell debris after being sonicated for 10 min on ice. The supernatant was precipitated by adding four times volumes of cold acetone. The precipitated protein was resuspended in 8 M urea/100 mM TEAB (pH 8.0). The proteins were then reduced with 10 mM dithiothreitol at 56 °C, alkylated with 50 mM iodoacetamide in the dark and diluted four times with 100 mM TEAB (pH 8.0) prior to overnight digestion with trypsin (1:50 w/w). The resulting peptides were desalted with Sep-Pak C18 column (Waters, MA, USA).

iTRAQ labeling and phosphopeptides enrichment

The experimental procedure of labeling peptides with iTRAQ and phosphopeptides enrichment followed that of *Chang et al. (2018)*.

LC-MS/MS analysis

All samples were analyzed using a Q Exactive HF-X mass spectrometer (Thermo Fisher Scientific, Waltham, MA, USA) coupled with the UltiMate 3000 RSLC nanosystem (Thermo Fisher Scientific, Waltham, MA, USA). Peptides were injected onto a C18 trap column (3 μm, 120 Å, 100 μm × 20 mm) and eluted at 300 nL/min onto a C18 analytical column (2 μm, 120 Å, 750 μm × 150 mm). The eluted peptides were sprayed into the mass spectrometer and scanned in the data-dependent acquisition (DDA) mode. The full MS settings were as follows: resolution: 60,000; scan range: 350–1800 m/z; AGC: 3e⁶; maximum injection time: 20 ms. The MS/MS settings were: resolution: 15,000; AGC: 2e⁵; maximum injection time: 100 ms.

Protein identification and bioinformatics analysis

The raw data were processed and the iTRAQ-labeled proteome was quantitatively analyzed by Maxquant software (1.6.17.0). The retrieval database was from National Center for Biotechnology Information ([GCF_001858045.2](https://www.ncbi.nlm.nih.gov/blast/) for *O. niloticus* and [GCF_013358895.1](https://www.ncbi.nlm.nih.gov/blast/) for *O. aureus*). The quantitative method was set to iTRAQ 8plex and the FDR (false discovery rate) was adjusted to < 0.01. The reverse decoy database was employed to identifications. Trypsin/P was specified as the cleavage enzyme. Oxidation on Met, N-terminal acetylation of protein, desamidization of asparagine and phosphorylation of serine, threonine and tyrosine were specified as variable modifications. Domain analysis was performed using Interproscan 5.0 (IPR). Gene Ontology (GO) annotations of proteomic and phosphoproteomic data were performed based on the UniProt-GOA database (<http://www.ebi.ac.uk/GOA/>). The Kyoto Encyclopedia of Genes and Genomes (KEGG) database (<https://www.genome.jp/kegg/>) was used for annotation analysis of protein pathways, and protein interaction analysis was performed using STRING 11.5.

Statistical analysis

Difference analysis was performed using the in-house *t*-test. The *p*-value ≤ 0.05 , and the fold change ≥ 1.5 (up-regulated expression) or the fold change ≤ 0.67 (down-regulated expression) were considered significant changes. All data were subjected to a *t*-test using SPSS 19.0 (Michigan Avenue, Chicago, IL, USA). Enrichment analysis is calculated using hypergeometric tests, with *p*-value ≤ 0.05 as the threshold.

RESULTS

Quality analysis of mass spectrometry data

Peptide length distribution and protein coverage distribution

Figure 1 shows that the length of the identified peptides mainly distributed between seven and 17 amino acids, which was consistent with the molecular weight range detected by the mass spectrometer. Among that, the number of the identified peptides with 9-13 amino acids exceeds 900. As shown in Fig. 2, the coverage ranges for the identified proteins are concentrated in (0-10) and (10-20). The rate of number of (0-10) protein coverage exceeds 70%.

Generation and analysis of the proteome and phosphoproteomics dataset

The data obtained by mass spectrometry were filtered for validity. For *O. niloticus*, a total of 11,333 peptides and 3,890 proteins were obtained from liver tissue, with 9,573 modification sites on 3,184 modified proteins identified. For *O. aureus* liver tissue, a total of 11,478 peptides, 3,891 proteins, and 9,706 modification sites on 3,197 modified proteins were identified (Table 1).

Analysis of protein phosphorylation modification sites

We analyzed the number of phosphorylation sites of all identified proteins in the liver tissues. As shown in Fig. 3A, proteins with one-site phosphorylation dominated all identified ones, accounting for about 40.77% of all identified proteins, followed by those phosphorylated at two sites (21.08%) and five sites (14.03%).

For eukaryotes, phosphorylation modifications occur primarily at serine (S), threonine (T) and tyrosine (Y) sites. Therefore, we also counted the proportion of these three sites among all detected sites. Figure 3B shows that the main phosphorylation site was serine (S), which accounted for 83.9% of all phosphorylation sites.

Global identification of proteomics and phosphoproteomic alterations in *O. aureus* and *O. niloticus*

The proteomic analysis on *O. aureus* liver shows that 3,891 proteins were identified and 1019 quantified in total (Table 2). For *O. niloticus* liver, 1,026 out of 3,890 identified proteins were quantified (Table 2).

For *O. niloticus* at 10 °C and 30 °C, comparative proteomics shows that 832 phosphorylation sites corresponding to 645 phosphoproteins were significantly differentially expressed, including 456 up-regulated expressed phosphosites (corresponding

to 337 phosphoproteins) and 376 down-regulated expressed phosphosites (corresponding to 308 phosphoproteins) (Table 3). A total of 104 (13.2%) phosphoproteins with different expressed phosphosites were present in the proteome expression dataset. Moreover, the phosphorylation sites and protein expression levels of five phosphorylated proteins (myoglobin, ATP-citrate synthase, coatomer subunit alpha, NADP-dependent malic enzyme and uncharacterized protein) were significantly decreased.

Species	Proteins quantified	Proteins quantified
<i>O. niloticus</i>	3891	1019
<i>O. aureus</i>	3890	1026

In the case of *O. aureus*, 486 phosphorylation sites corresponding to 381 phosphoproteins were significantly differentially expressed between 10 °C and 30 °C groups, including 231 up-regulated (corresponding to 172 phosphoproteins) and 255 down-regulated expressed phosphosites (corresponding to 209 phosphoproteins) (Table 3). Comparison between proteomics and phosphoproteomics findings shows 52 (12.1%) phosphoproteins with different expressed phosphosites in the proteome expression dataset. In addition, one phosphorylated protein (NADP-dependent malic enzyme) was found to decrease in the phosphorylation site and the protein expression level.

Functional enrichment analysis of phosphoproteomics

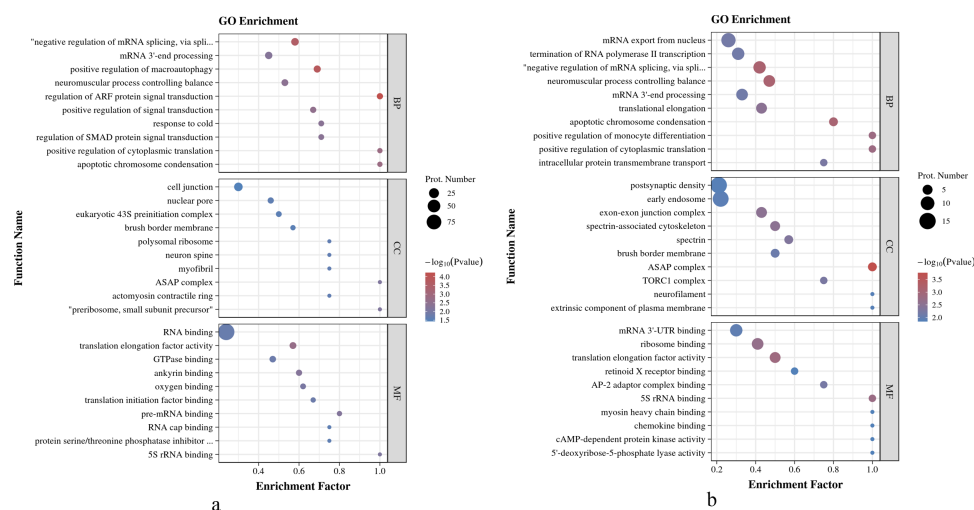

We performed functional enrichment analyses of GO, KEGG, and IPR for the phosphorylated proteins with significantly differential expressed phosphorylation sites.

GO enrichment analysis

As shown in Fig. 4A, in *O. niloticus*, phosphorylated proteins were enriched in the top five biological process (BP) terms, including regulation of ARF protein signal

Table 3 Global statistics of phosphoproteomic in *O. niloticus* and *O. aureus*.

Species	Down-regulated phosphosites (corresponding to phosphoproteins)	Up-regulated phosphosites (corresponding to phosphoproteins)	Phosphoproteins present in the proteome expression dataset
<i>O. niloticus</i>	376 (308)	456 (337)	104

transduction, positive regulation of macroautophagy, negative regulation of mRNA splicing, *via* spliceosome, apoptotic chromosome condensation and positive regulation of cytoplasmic translation; enriched in the top five molecular function (MF) terms: translation elongation factor activity, ankyrin binding, pre-mRNA binding, 5S rRNA binding and oxygen binding; enriched in the top three cellular component (CC) terms: pre-ribosome, small subunit precursor, ASAP complex and myofibril. As shown in [Fig. 4B](#), in *O. aureus*, phosphorylated proteins were enriched in the top five BP terms, including negative regulation of mRNA splicing, *via* spliceosome, neuromuscular process controlling balance, apoptotic chromosome condensation, positive regulation of cytoplasmic translation and positive regulation of monocyte differentiation; enriched in the top five MF terms: translation elongation factor activity, 5S rRNA binding, ribosome binding, AP-2 adaptor complex binding and mRNA 3'-UTR binding; and enriched in the first three CC terms: ASAP complex, exon-exon junction complex and spectrin-associated cytoskeleton.

KEGG enrichment analysis

As shown in [Figs. 5A](#) and [5B](#), in *O. niloticus*, phosphorylated proteins corresponding to differential expressed phosphorylation sites were mainly enriched in carbohydrate digestion

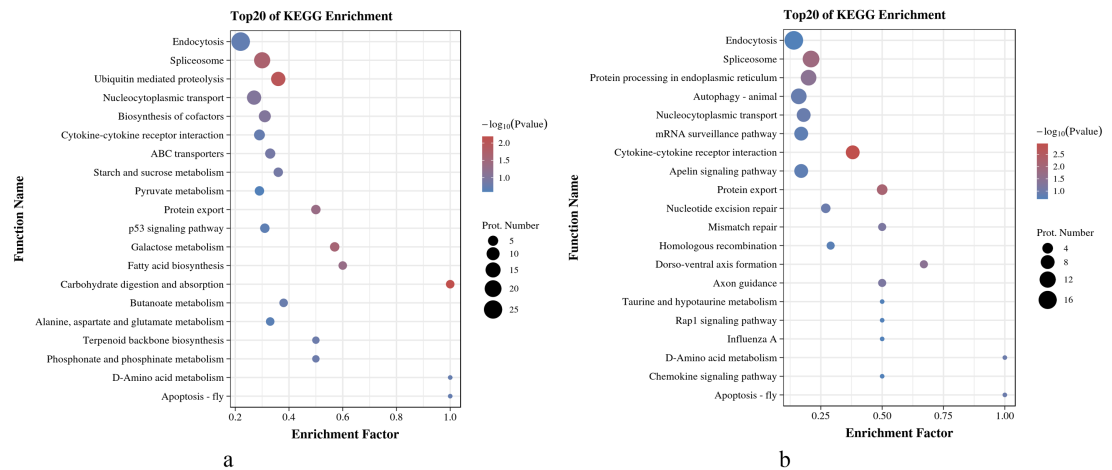

Figure 5 KEGG enrichment analysis of phosphorylated proteins with significantly differential phosphorylation sites from *O. niloticus* and *O. aureus*. and absorption, ubiquitin-mediated proteolysis, spliceosome and other pathways. As for *O. aureus*, the phosphorylated proteins were mainly enriched in cytokine-cytokine receptor interaction, protein export, spliceosome and other pathways.

IPR enrichment analysis

As shown in Figs. 6A and 6B, the IPR enrichment of phosphorylated proteins corresponding to differential expressed phosphorylation sites showed certain similarities between *O. niloticus* and *O. aureus*. Transcription elongation factor S-II, central domain superfamily, transcription elongation factor S-II, Sec7 domain, RNA-binding domain superfamily and other terms were highly enriched in both species. However, the levels of enrichment significance of these domains were inconsistent between the two tilapia species. In addition, there are also many enrichment differences between these two tilapias. For example, more proteins with zinc finger domain enrich in *O. niloticus*, and in *O. aureus* includes acinus motif and so on.

Interaction analysis of phosphorylated proteins

We initially compared the enrichment of differentially expressed phosphorylated proteins between the two tilapias and analyzed the first few terms with highest enrichment significances. Under low-temperature stress, the apoptotic chromatin condensation inducer and CAD protein, which were enriched in negative regulation of mRNA splicing term and apoptotic chromosome condensation term, showed similar differences in phosphorylation reduction levels. In this regard, we conducted the interaction analysis for these proteins. Analysis based on the *O. niloticus* reference library revealed that, the proteins that may interact with the apoptotic chromatin condensation inducer in the nucleus included Api5, Sap18, Pabpn and some undefined proteins, etc. Based on the zebrafish reference library,

however, proteins such as Otc, Cps1 and Ass1 may interact with CAD protein (Figs. 7A, 7B).

We also conducted an interaction analysis on the IQ motif and SEC7 domain-containing proteins in the regulation of ARF protein signal transduction term in both species, which differed more significantly in *O. niloticus*. In *O. aureus*, the neuromuscular process controlling balance and positive regulation of monocyte differentiation terms enriched phosphorylated proteins, such as tyrosine-protein kinase ABL1. Based on the *O. niloticus* database, the proteins that may interact with IQ motif and SEC7 domain-containing

proteins included Inpp5f, Psd4, Glur2b, etc. Using the zebrafish database as a reference, the proteins that may interact with tyrosine-protein kinase ABL1 included Rad51, CRK, ATM, etc. Figs. 8A, 8B.

DISCUSSION

Post-translational modification is an essential way by which eukaryotes regulate the biological function of proteins. Phosphorylation is one of the most important post-translational modifications of protein, and it is a reversible process. This reversible process involves almost all physiological processes of the body, including cell signal transduction, gene expression, cell proliferation, development, differentiation and apoptosis, nerve activity, tumorigenesis, and so on (Johnson, 2009; Nirujogi et al., 2015; Weber, Schreiber & Daub, 2012).

In this study, we found that protein expression of NADP-dependent malic enzyme changed significantly in the livers of two tilapias, and its phosphorylation level also showed significant changes. The NADP-dependent malic enzyme is mainly involved in the physiological process of lipid metabolism (Barroso et al., 2001; Chang & Tong, 2003; Hsieh et al., 2019). Studies have confirmed that the dynamic regulation of phosphorylation and acetylation of malic enzyme affects lipid metabolism, and NADP-dependent malic enzyme becomes inactive after phosphorylation (Zhu et al., 2020). In addition, low temperatures can increase malic enzyme synthesis, thus increasing the synthesis of fatty acids. The newly synthesized fatty acids are mainly used in membrane phospholipids synthesis, thus resisting low-temperature stress (Viola et al., 1988). When fish are subjected to low-temperature stress, lipid metabolism has been reported to be one of the earliest biological processes that are significantly altered (Abdel-Ghany et al., 2021; Nobrega et al., 2020; Snyder & Hennessey, 2003). In this study, the significant changes in protein expression and phosphorylation level of NADP-dependent malic enzyme in the two tilapias also suggested the vital role

of lipids as a critical energy source in fish's response to low-temperature stress. Besides, the lipid levels might be correlated with the low-temperature tolerance of fish. Moreover, many studies also found that the expression of many genes related to lipid metabolism changed significantly when fish were under low-temperature stress ([Liu et al., 2020](#); [Nie et al., 2016](#); [Sun et al., 2019](#)). In this study, the basic biological process of the two tilapias when coping with the low temperature is similar.

In addition, by comparing the enrichment of differentially phosphorylated proteins in the livers of the two tilapias and analyzing the top terms with high enrichment significance, we found that a variety of phosphorylated proteins were involved in similar biological processes in the two tilapias facing low-temperature stress. For example, many proteins involved in the related apoptotic biological process were significantly enriched. Many studies have demonstrated that apoptosis is involved in the response of fish to low-temperature stress ([Hu et al., 2016](#); [Reid et al., 2022](#); [Ren et al., 2021](#)). When fish were subjected to low-temperature stress, the various apoptosis pathways, namely the mitochondrial pathway, endoplasmic reticulum pathway and death receptor pathway, had significant changes. For instance, the expression of many apoptosis-related genes, such as the caspase family and the BCL-2 family, was up-regulated in orange-spotted grouper at cold temperatures ([Sun et al., 2019](#)). When zebrafish are exposed to the low temperature, cold can induce endoplasmic reticulum (ER) stress and apoptosis ([Chen et al., 2019](#)). In addition, in our previous studies, many apoptosis-related genes, including GAS2 genes and BCL-2 family genes, participated in the process of tilapia coping with low-temperature stress ([Yang et al., 2017](#); [Yang et al., 2020](#)).

In this study, we found that the phosphorylation levels of apoptotic chromatin condensation inducer in the nucleus (ACIN1) and CAD proteins changed significantly in both tilapias (see [Table S2](#)). ACIN1 is an RNA-binding protein directly involved in RNA processing, and it plays an important role in cell apoptosis and apoptosis chromosome concentration ([Lin et al., 2020](#); [Sahara et al., 1999](#)). In addition, the expression of ACIN1 may be related to fat synthesis ([Lin et al., 2020](#)). The function, stability and activity of ACIN1 depend on its phosphorylation ([Nandi & Kramer, 2018](#)). However, considering the results of IPR enrichment analysis, the protein with acinus motif was more significantly enriched in *O. aureus*. It is speculated that those difference in phosphorylation protein in the two tilapias may affect their low temperature tolerance. CAD protein is a multifunctional enzyme with DNase activity. Caspases can cleave CAD inhibitors and activate CAD, which causes DNA cleavage and cell apoptosis ([Enari et al., 1998](#); [Kimura et al., 2004](#); [Larsen et al., 2010](#)). The activity of CAD protein is regulated by protein phosphorylation reaction ([Nakashima et al., 2013](#)). In this study, we also analyzed the protein interaction network of ACIN1 and CAD. We found that the proteins that may interact with these two proteins are involved in physiological activities such as transcriptional, post-translational regulation and apoptosis. For example, the Api5 (apoptosis inhibitor 5) participates in cell apoptosis as an effective inhibitor ([Chen et al., 2021](#)), whereas the Sap18 and Pabpn are involved in the post-transcriptional and post-translational modification processes, respectively ([Nicholson & Pasquinelli, 2019](#); [Zhang et al., 1997](#)).

At the same time, we further compared the different expressed phosphorylated proteins that were enriched in the apoptotic chromosome condensation in the two tilapias and found notable differences between the two tilapias. For example, the phosphorylation level of Serine/Arginine-Rich Splicing Factor 6 (SRS F6) was significantly up-regulated in *O. niloticus*, while that of Serine/Arginine-Rich Splicing Factor 9 (SRS F9) was significantly down-regulated in *O. niloticus*. But those was just the opposite in *O. aureus* (see [Table S2](#)). The serine/arginine-rich splicing factors (SRSFs) are a class of serine/arginine-rich splicing factors, *i.e.*, a class of trans-acting factors that play a crucial role in pre-mRNA splicing ([Wagner & Frye, 2021](#)). As members of the SRSF family, SRSF6 and SRSF9 can promote cell proliferation and migration ([Jensen, Wilkinson & Krainer, 2014](#); [Wang et al., 2022](#)). Meanwhile, SRSF6 has also been found to be involved in the alternative splicing of apoptosis-related *FAS* gene ([Choi et al., 2022](#)). SRSF9 can inhibit caspases 3/7 and reduce cell apoptosis. The phosphorylation of SRSF6 and SRSF9 regulates the function of their alternative splicing ([Li et al., 2021](#); [Ninomiya et al., 2020](#)). However, there is still much to learn about the function of SRSF. In this study, the phosphorylation differences of SRSF between the two tilapias under low-temperature stress may be associated with their different cell apoptosis levels, but its function needs further analysis.

Additionally, phosphorylated proteins involved in the regulation of ARF protein signal transduction and positive regulation of macroautophagy showed significant changes in *O. niloticus*. These proteins included several ARF-related proteins, such as the IQ motif and sec7 domain-containing protein, as well as the brefeldin a-inhibited guanine nucleotide-exchange protein 2 (see [Table S2](#)). ARF protein signal transduction has multiple physiological functions, including secretion, endocytosis, phagocytosis and signal transduction ([Donaldson & Jackson, 2011](#)). The activity of ARF protein is mainly regulated by binding GTP ([Goldberg, 1998](#)). However, in *O. aureus*, the top five significantly enriched BP terms of differentially phosphorylated proteins included the neuromuscular process controlling balance and positive regulation of monocyte differentiation, which was different from that in *O. niloticus*. The proteins involved in these BP terms included SH3, multiple ankyrin repeat domains protein 3 and tyrosine-protein kinase ABL1 (see [Table S2](#)). The function of these proteins is mainly related to nerve development, cell division and growth ([Kim et al., 2020](#); [Luan et al., 2021](#)). Together, our results indicated that the physiological processes involved in the low temperature tolerance acted differently in the two tilapias.

According to the IPR enrichment analysis in the two tilapias, although the differentially phosphorylated proteins were enriched to many similar domains, for example, the SEC7 domain, the enriched significance of phosphorylated proteins with the same domain in *O. aureus* was less than that in *O. niloticus*. In these domains, the SEC7 domain is a conservative core domain in Arf family proteins ([Mouratou et al., 2005](#); [Pipaliya et al., 2019](#)), that is responsible for the catalytic function that catalyzes the exchange of GDP for GTP on the ARF family of small GTP-binding proteins ([Donaldson & Jackson, 2000](#); [Jackson & Casanova, 2000](#)). ARF proteins are significant regulators of membrane dynamics and protein transport within the eukaryotic cell ([D'Souza-Schorey & Chavrier, 2006](#)). Many studies have reported that the cell membrane also plays an important role in fish subjected

to low-temperature stress, and the low environmental temperature will affect the fluidity and integrity of fish cell membranes (Wang *et al.*, 2014). The membrane of fish adapted to cold environments is more fluid than that of fish adapted to warm environments (Farkas *et al.*, 2001). Similar to the above results, the phosphorylation level of Arf family members related to cell membrane integrity and transport changed significantly when the two tilapias were subjected to low-temperature stress in the present study. Furthermore, the differences in the enrichment level of these protein members may also be one of the factors affecting their abilities to cope with low-temperature stress.

Comparing the MF enrichment between the two tilapias, proteins corresponding to different phosphorylation sites were enriched in similar MF terms, involving the translation elongation factor activity and various binding terms. However, for the binding term, there were some differences between the binding objects and the significant level of enrichment between the two tilapias. For example, ankyrin binding, mainly involved in link cytoskeleton (Gil *et al.*, 2003), and oxygen and GTPase binding involved in energy metabolism, were more significantly enriched in *O. niloticus*. In *O. aureus*, the AP-2 adaptor complex binding of clathrin-mediated endocytosis from the plasma membrane (Holman & Sandoval, 2001), mRNA 3'-UTR binding and retinoid X receptor binding were more significantly enriched, which play an important role in post-transcriptional regulation (Son & Paton, 2020).

In addition, the results of the KEGG enrichment analysis showed some differences between the two tilapias. For example, the carbohydrate digestion and absorption pathways were more enriched in *O. niloticus*. The oxidative decomposition of carbohydrates is an essential energy source for fish. Many studies have confirmed that low temperature significantly reduces the initial energy reserve (including lipids and carbohydrates) of fish and significantly increases energy consumption (Wen *et al.*, 2017). At the same time, the expressions of genes related to energy metabolism pathway also change significantly (Qian & Xue, 2016; Xu *et al.*, 2018). Our results indicate that low-temperature stress had a more severe effect on the energy metabolism of *O. niloticus*. The more prominent pathways in *O. aureus* were the cybernetic-cybernetic receptor interaction, protein export and so on. Further analysis, this pathway contains interferon alpha/beta receptor 2, interleukin-1 receptor, C-X-C chemokine receptor, and growth hormone receptor genes. It indicating that the immunity and growth of *O. aureus* may be more affected by low-temperature stress.

CONCLUSIONS

To summarize, the comparative phosphorylation proteomics showed that the main physiological activities (*e.g.*, energy metabolism, immunity, apoptosis, *etc.*) affected by low-temperature stress in the two tilapias was similar, and the difference in endurance of low temperature of these two tilapias might be related to the differences in categories, expression and modification level of genetic products which were involved in the aforementioned physiological processes.

ACKNOWLEDGEMENTS

Thanks to Zhiying Zou for the help in tilapia preparation.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the Innovation Projects of Universities in Guangdong Province (No. 2021KTSCX067) and the China Agriculture Research System (No. CARS-46). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:

The Innovation Projects of Universities in Guangdong Province: 2021KTSCX067.

China Agriculture Research System: CARS-46.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Changgeng Yang conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.
- Hua Fan performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.
- Liya Ge performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.
- Qian Ma analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.
- Ming Jiang performed the experiments, authored or reviewed drafts of the article, and approved the final draft.
- Hua Wen performed the experiments, authored or reviewed drafts of the article, and approved the final draft.

Animal Ethics

The following information was supplied relating to ethical approvals (i.e., approving body and any reference numbers):

The care, handling, and sampling of fish were performed following animal care protocols approved by the Laboratory Animal Centre of Yangtze River Fisheries Research Institute, Chinese Academy of Fishery Sciences.

DNA Deposition

The following information was supplied regarding the deposition of DNA sequences:

The data of peptide sequencing is available in the [Supplemental Files](#).

Data Availability

The following information was supplied regarding data availability:

The raw measurements are available in the [Supplementary Files](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.15599#supplemental-information>.
