Running Title: Ferrostatin-1 AKI Mitigation via Ferroptosis Inhibition in Mice

Abstract

Background: Acute kidney injury (AKI) is a common and serious medical condition with high morbidity and mortality. Recent research has highlighted ferroptosis, a novel form of programmed cell death, as a potential therapeutic target in mitigating renal tubular injury in AKI. Ferrostatin-1, a specific ferroptosis inhibitor, has been demonstrated to prevent renal injury through ferroptosis inhibition.

Methods: Utilizing a murine AKI model, we investigated the effects of Ferrostatin-1 by administering it post-injury. Through high-throughput sequencing and pathological analysis, we focused on the critical role of ferroptosis-related pathways in the treatment.

Results: Ferrostatin-1 post-conditioning effectively mitigated oxidative damage and reduced iron content associated with AKI. Additionally, critical ferroptosis-related proteins, such as GPX4,

SLC7A11, NRF2, and FTH1, exhibited increased expression levels. In vitro, Ferrostatin-1 treatment of HK-2 cells significantly diminished lipid peroxidation and iron accumulation. Furthermore, Ferrostatin-1 was found to downregulate the PI3K signalling pathway.

Conclusion : Ferrostatin-1 acted as a potential ferroptosis inhibitor with the capacity to enhance antioxidant defences. This study suggests that Ferrostatin-1 could serve as a promising novel strategy for improving the treatment of AKI and promoting recovery from the condition.

Keywords: Iron death, Acute kidney injury, Ferrostatin-1

1. Introduction

Acute kidney injury (AKI), typified by a rapid deterioration in renal function, is a common and serious medical condition with high morbidity and mortality. Often secondary to extrarenal events, AKI affects approximately 30% of critically ill patients and 5% of hospitalized patients [1]. The molecular mechanisms underlying AKI remain incomplete, and current prevention and treatment options are limited. Finding effective drugs that can preserve renal function and improve the prognosis of AKI in clinical practice is an urgent need.

Ferroptosis, a recently identified cell death mode, is different from necrosis, and is characterized by a unique morphological phenotype, excessive accumulation of lipid peroxides, and increased levels of free iron [2]. This cell death pathway has been implicated in diseases, such as Parkinson's and Alzheimer's, cancer, stroke, ischemia-reperfusion injury, intracranial haemorrhage, and brain injury. Numerous studies have recently established a potential association between ferroptosis and AKI [3-8].

Glutathione peroxidase 4 (GPX4), a key biomarker of ferroptosis, is responsible for reducing lipid peroxide, which requires glutathione (GSH) as the substrate[9]. System Xc⁻ is an amino acid reverse transport protein that exists in the cell membrane and is composed of SLC7A11 and SLC3A2 heterodimers. The transport system Xc⁻ is responsible for the exchange of intracellular glutamate and extracellular cystine[10]. Cystine could be converted into Cysteine in the cell and becomes the synthesis substrate of GSH. GSH further cooperates with GPX4 to exert an antioxidant effect and maintain cellular redox balance. Therefore, the inactivation or abnormal expression of system Xc⁻ will affect the ability of cells to process ROS. Studies have found that if the total amount of amino acids (especially cystine) in serum were deficient in vitro, it would cause rapid cell death. Later, it was confirmed that this type of cell death is ferroptosis [11]. Early studies have confirmed that system Xc⁻ is abundant in the brush border membrane of renal tubular cells (anatomically, the part where the kidney mainly carries out amino acid transport) [12]. Inhibition of system Xc⁻ or ischemic state will lead to the lack of amino acid supply, intracellular GSH level decreased, and the antioxidant capacity diminished, leading to ferroptosis and renal tubular injury. In addition, ferritin heavy chain 1 (FTH1) is responsible for intracellular iron storage. NF-E2-related factor 2 (NRF2) is the transcription regulator of GPX4, SLC7A11, FTH1 and other iron death-related proteins. These factors were considered biomarkers of ferroptosis.

Recent studies have shown that ferroptosis plays a crucial role in regulating AKI. Ferroptosis was observed in various types of AKI, such as AKI induced by cisplatin, rhabdomyolysis, ischemia/reperfusion, or folic acid. The purpose of this study was to confirm that Ferrostatin-1, a candidate ferroptosis inhibitor, may reduce AKI by reversing ferroptosis and alleviating lipid peroxidation and iron accumulation in vitro model and in vivo model. We then explored the pathway involved by transcriptome analysis, expecting to provide a new strategy for the clinical treatment of AKI.

2 Materials & Methods

2.1 Cell culture and treatment

Human proximal tubular epithelial cells (HK-2 cells) were cultured in a atmosphere comprised of 95% air and 5% CO₂ at 37 °C. HK-2 cells were seeded into culture plates at 5×10^5 cells/well and cultured 24 h before each experiment. Subsequently, we added LPS (10 µg/ml) into the cultured cells for 22 h to establish the cell model of LPS-induced AKI[13]. Then, Ferrostatin-1 was added into the HK-2 cells according to previous study [14]. The HK-2 cells were divided into 3 groups: the control group, LPS-induced (10 µg/ml) AKI group, and LPS-induced (10 µg/ml) + Ferrostatin-1 (1 µM) group. The experiments were approved by the Ethics Committee of Baoshan people's Hospital(SYSU-IACUC-2020-A0327).

2.2 Animals and experimental protocol

C57BL/6 mice weighing 20-25 g were procured for this study and housed in a temperature and humidity-controlled environment with a 12-hour light-dark cycle, while being fed standard food and water ad libitum. The study was approved by the Animal Ethics Committee of Baoshan People's Hospital. The AKI model in vivo was established as previously described [15]. All mice received intraperitoneal administration of pentobarbital (50 mg/kg) and AKI was induced via cecal ligation and puncture (CLP) with a 22-gauge needle. The sham/Con group mice underwent the same procedure without cecal ligation or puncture. Subsequently, pre-warmed normal saline at a dosage of 1 ml per 25 g body weight was administered subcutaneously. At 5 h after CLP, either normal saline (NS, 0.5 ml, vehicle) or Ferrostatin-1 (ferrostatin-1, 1.5 mg/kg, a ferroptosis inhibitor; Sigma-Aldrich, MO, United States) was intravenously administered. At 24 h after intravenous injection, the animals were euthanized and blood and kidney tissues were collected for further experiments. The mice were divided into three groups: the Sham/Con group, the CLP group, and the CLP + Ferrostatin-1 (1 µM) group.

Animal care, including feeding, housing, and enrichment, was carried out according to established guidelines. Criteria for euthanizing animals were established prior to the planned end of the experiment. Any surviving animals at the conclusion of the experiment were monitored and accounted for accordingly.

2.3 BUN and Cr Detection

The serum gathered from the blood samples by centrifugation (3000 rpm, 5 min, 4 °C) were used to evaluate renal function. The levels of serum BUN and Cr were detected by the commercial assay kit - Urea assay kit (Nanjing Jiancheng, China) and Creatinine assay kit (sarcosine oxidase) (Nanjing Jiancheng, China), according to the manufacturer's instructions, respectively.

2.4 ROS Detection

The level of ROS in the renal tissues was determined by Dihydroethidium (DHE) fluorescence with a DCFH-DA assay kit. Renal tissues were stored at -20 °C until the fluorescence assay. The blocks were cut on polylysine-coated glass slides and incubated with 10 µM DHE for 30 min at 37 °C and then incubated with DAPI solution at room temperature for 10 min, kept in the dark place. Washing the tissues with PBS 3 times at room temperature, and the tissues were then incubated with the DCFH-DA staining solution for 1 h at 37°C. Images were captured using a fluorescence microscope.

The levels of ROS in HK-2 cells were also tested by the DCFH-DA assay kit following the manufacturer's instructions. HK-2 cells were seeded on 35 mm laser confocal petri dishes at a density of 1.0×10^5 cells per well and cultured at 37°C for 24 h with 95% air and 5% CO₂. The HK-2 cells were treated with Ferrostatin-1 (1 µM) for 24 h and then were treated with DCFH-DA for 20 min in dark. After that, the HK-2 cells were washed with PBS 3 times to remove DCFH-DA and the images of samples were captured by a fluorescence microscope.

2.5 Histopathological Analysis

The renal samples were dissected and fixed with paraformaldehyde. Then, renal samples were paraffin-embedded, sliced into 4-µm slices, and stained with HE (hematoxylin and eosin) [16]. The specimens were evaluated in a blinded manner.

2.6 Quantitative real-time polymerase chain reaction

RNA was extracted and real-time polymerase chain reaction (PCR) of HK-2 cells and kidney samples were performed [17]. The PCR reaction volume was 20 µl, including 30 ng RNA as the template and 12 µl SYBR Green PCR Master Mix (Applied Biosystems). Gpx4 forward primer sequences were 5'-CCGGCTACAATGTCAGGTTT-3' and reverse primer sequences were 5'-ACGCAGCCGTTCTTATCAAT-3'; SLC7A11 forward primer sequences were 5'-GATGCTGTGCTTGGTCTTGA-3' and reverse primer sequences were 5'-GCCTACCATGAGCAGCTTTC-3'; NRF2 forward primer sequences were 5'-CTTTTATCTCACTTTACCGCCCGAG-3' and reverse primer sequences were 5'-GACACGTGGGAGTTCAGAGGG-3' and FTH1 forward primer sequences were 5'-ATGATGTGGCCCTGAAGAAC-3' and reverse primer sequences were 5'-TCATCACGGTCAGGTTTCTG-3'. PCR conditions were 95 °C for 5 min, followed by 36 cycles of 30 s at 94.5 °C, 30 s at 60 °C, and 60 s at 72 °C, and at 72 °C for 7 min as the final extension. The relative expression of the genes of each specimen was analyzed using a comparative CT method with $2^{-\Delta\Delta C_t}$.

2.7 Western Blot Analysis

We performed Western blot as previously recorded [18,19]. Firstly, the proteins extracted from renal tissues or HK-2 cells were lysed with RIPA solution, proteins were collected and their concentrations were determined, followed by electrophoresis in 10% SDS-polyacrylamide gel. After electrophoresis, the proteins were transferred to PVDF membrane, sealed with TBST blocking solution containing 5% nonfat milk powder for 2 h. The primary antibody was added and incubated at 4 °C overnight, followed by the second antibody incubated at room temperature for 2 h. After washing the blots, chemiluminescent reagent was added. The band images were taken by ImageJ gel software and the gray value of the detected protein was calculated.

2.8 Detection of Glutathione (GSH) and Malondialdehyde (MDA) Levels

The levels of malondialdehyde (MDA) and glutathione (GSH) in HK-2 cells and kidney tissues were determined with the commercial assay kit purchased from Nanjing Jiancheng Bioengineering Institute (Nanjing, China), following the respective manufacturer's instructions. A microplate fluorometer read individual levels of MDA and GSH at 532 or 405 nm according to the manufacturer's instructions, respectively[20].

2.9 Iron assay

Intracellular and tissue levels of total iron were assessed using an iron assay kit (Sigma-Aldrich). Total iron levels in HK-2 cells or kidney tissue samples were measured using an iron assay kit (Sigma-Aldrich). HK-2 cells or kidney tissue samples were harvested and homogenized in iron assay buffer and centrifuged. 10 µl supernatant was mixed with 90 µl iron analysis buffer and 5µl iron reductant. The mixture was incubated for 30 min and the total iron levels were measured using an iron probe with a wavelength of 593nm.

2.10 Transcriptome sequencing

Samples were collected from the Ferrostatin-1 and AKI groups (n = 3 of each group). The samples were put into the enzyme-free Eppendorf tubes. After the samples were frozen in liquid nitrogen, they were wrapped in dry ice and transported to the company for total RNA extraction and sequencing processing. Use high-throughput sequencing to analyze differentially expressed genes and find relevant pathways.

2.11 Statistical analysis

All data in this study was expressed as mean ± standard deviation (SD) and was analyzed using SPSS statistical software package (SPSS, Inc., Chicago, IL, USA). Differences between means were compared using the Student's t-test. One-way analysis of variance (ANOVA) and Dunnett

multiple comparison test were also used for analysis, and a P value < 0.05 was considered statistically significant.

3. Results

3.1 Ferrostatin-1 treatment Protects Against AKI in the mice Model

The impact of Ferrostatin-1 on the AKI was confirmed by adding Ferrostatin-1 to the AKI group. Figure 1A shows significant pathological changes in the AKI model. In the Sham/Control group, the renal tissue morphology was normal, the structure was clear, the cells were regularly arranged, and there was no inflammation or fiber exudation; while in the AKI model group, there was brush like edge damage, proximal tubular dilation, interstitial widening, proteinaceous casts and necrosis. Compared with the AKI model group, the Ferrostatin-1-treatment group showed alleviated pathological changes of brush like edge damage, proximal tubular dilation, interstitial widening, proteinaceous casts and necrosis. As shown in Figure 1C and Figure 1D, compared with the Sham/Control group, the concentration of serum BUN and Cr in the AKI model group was significantly higher. And the levels of serum BUN and Cr were decreased after the administration of Ferrostatin-1, but still higher than those of the Sham/Control group. These results indicated that Ferrostatin-1 can significantly mitigate kidney injury.

3.2 Ferrostatin-1 Attenuates Ferroptosis During AKI

To further prove that the protection of Ferrostatin-1 on AKI referred to Ferroptosis, the tissue ROS production and lipid ROS level (MDA and GSH) were measured. AKI markedly increased the generation of ROS and MDA levels and decreased the GSH activity, whereas Ferrostatin-1 post-conditioning inhibited the oxidative damage caused by AKI (Figure 1B, Figure 1E, F). Secondly, the iron content and the expressions of GPX4, SLC7A11, NRF2 and FTH1 were valued. In the AKI model group, the iron content (Figure 1G) increased while the expressions of GPX4, SLC7A11, NRF2 and FTH1 decreased. However, post-treatment with Ferrostatin-1 suppressed these alterations (Figure 2). These finding suggested that post-treatment with Ferrostatin-1 mitigated AKI by inhibiting ferroptosis.

3.3 Ferrostatin-1 Mitigates Ferroptosis in LPS-Induced HK2 Cells

Based on the findings mentioned earlier *in vivo*, we next evaluated the function of Ferrostatin-1 on LPS-induced AKI. In Figure 3A, there were significant pathological changes in the LPS-induced AKI model, such as brush border damage, proximal tubule dilation, interstitial widening, proteinaceous casts and necrosis. As shown in Figure 3B, post-treatment with Ferrostatin-1 induced ROS levels in LPS-induced AKI group. Similarly, post-treatment with Ferrostatin-1 prevented the decrease of the GPX4, SLC7A11, NRF2 and FTH1 expression in the Ferrostatin-1 treatment group (Figure 3C-K). Obviously, Ferrostatin-1 inhibited LPS-induced ferroptosis *in vitro*.

3.4 Ferrostatin-1 Inhibits LPS-Induced Ferroptosis Through the PI3K Pathway *In Vitro*

To fully understand the molecular mechanisms involved in the AKI, we performed high-throughput transcriptional sequencing to identify differentially expressed genes (DEGs) between the Ferrostatin-1 and LPS groups ($n = 3$ in each group). A total of 63677 genes were identified in the RNA-seq data set. The heatmap showed 5099 DEGs in the Ferrostatin-1 and LPS groups (Figure 4A). Furthermore, the volcano plot (Figure 4B) revealed 35 upregulated, and 26 downregulated DEGs in the Ferrostatin-1 group. The DEGs were also used for GO/KEGG analysis; the phosphatidylinositol 3-kinase signalling (PI3K) pathway was involved (Figure 4C), suggesting that ferroptosis may be associated with AKI. Consequently, these results further supported that Ferrostatin-1 may induce AKI in mice through ferroptosis by the PI3K pathway.

4. Discussion

The kidney, a vulnerable organ, significantly impacts septic patients' outcomes, as renal injury contributes to prolonged hospital stays and increased mortality rates [21,22]. Plenty of studies have established a correlation between the lipid peroxidation and ROS in AKI. Ferroptosis, a novel iron-dependent, lipid peroxidation-induced cell death pathway, has been recently identified [15]. The recent study investigated the effect of ferrostatin-1 and its potential efficacy in AKI therapy. The pivotal findings of this study encompass ferroptosis' involvement in AKI, the protective effect of Ferrostatin-1 post-treatment against AKI via ferroptosis inhibition, and Ferrostatin-1's protective mechanism's reliance on the PI3K pathway [21-23].

Recent investigations have revealed that the inhibition of GPX4 could diminish reduction of lipid peroxides[24]. GPX4 utilizes GSH and eliminates lipid peroxides [25]. Several studies have demonstrated that Ferrostatin-1 can inhibit ferroptosis and alleviate acute kidney injury[26,27]. In line with these findings, our study also revealed that post-treatment with Ferrostatin-1 could mitigate AKI. Since ferroptosis occurs during AKI, Ferrostatin-1 may offer a promising strategy for AKI prevention.

However, our study presents the following limitations. Firstly, our focus was on the impact of ferrostatin-1 on ferroptosis. Although the direct anti-ferroptosis effects of ferrostatin-1 were proved, we did not examine its influence on other types of cell death, such as autophagy and necroptosis. Secondly, the precise mechanism through which ferrostatin-1 modulates the PI3K pathway warrants further investigation.

5. Conclusions

In summary, AKI triggers ferroptosis by increasing iron contents and lipid peroxidation. Ferrostatin-1, acting as a ferroptosis inhibitor, enhances antioxidant capacity and effectively alleviates AKI by inducing the gene expression of lipid metabolism enzymes within the PI3K pathway. This study offers compelling evidence supporting the potential application of ferrostatin-1 in the treatment of AKI.

Data Availability Statement

This statement indicates that the article and any supplementary material contain the original contributions of the study. Readers who have further inquiries regarding the study can contact the corresponding authors for more information.

Ethics Statement

The ethical considerations of this study involving human participants were read and approved by the Animal Ethics Committee of Baoshan People's Hospital. All patients/participants provided written informed consent to participate in the study, and all procedures were conducted in accordance with the ethical standards outlined in the Declaration of Helsinki.

Author Contributions
