Background. Chemical mutagenesis has been successfully employed for increasing genetic diversity in crop plants. Through the successful application of several mutagenic agents, more than 800 new varieties have been produced in rice (*Oryza sativa* L.) as mutants. Among a wide variety of chemical mutagens, ethyl-methane-sulfonate (EMS) is the alkylating agent that is most commonly employed in crop plants because it frequently induces nucleotide substitutions as detected in numerous genomes.

Methods. In the current study, seeds of the widespread Basmati rice variety (Super Basmati, *Oryza sativa* L.) were treated with EMS at concentrations of 0.25%, 0.50%, 0.75%, 1.0%, and 1.25%.

Results. Mutagen-sensitivity of EMS was determined in the M_1 generation. Results in M_1 generation as compared to the control under field conditions revealed that as the levels of applied EMS increased, there was a significant reduction in the germination percent, root length, shoot length, plant height, productive tillers, panicle length, sterile spikelet, total spikelet, and fertility percent. All the aforementioned parameters decreased but there was an increase in EMS mutagens in an approximately linear fashion. Furthermore, there was no germination at 1.25% of EMS treatment for seeds, and 50% germination was recorded between EMS 0.50% and EMS 0.75% treatments. After germination, the subsequent parameters viz. root length and shoot length had LD_{50} between 05.0% and 0.75% EMS dose levels. Significant variation was noticed in the photosynthetic and water related attributes of the fragrant rice variety. A linear increase in the enzymatic attributes was noticed by the EMS-mediated treatments. After the establishment of the plants in the M_1 generation in the

field, it was observed that LD_{50} for fertility percent was observed at EMS 1%, for the rice variety.

Conclusion. Hence, it is concluded that for creating genetic variability in the rice variety (Super Basmati), EMS doses from 0.5% to 0.75 are the most efficient and effective.

Effect of ethyl methanesulfonate mediated mutation for enhancing morpho-physio-biochemical and yield contributing traits of fragrant rice

Abstract

Background.

Chemical mutagenesis has been successfully used for increasing genetic diversity in crop plants. More than 800 novel mutant types of rice (*Oryza sativa* L.) have been developed through the successful application of numerous mutagenic agents. Among a wide variety of chemical mutagens, ethyl-methane-sulfonate (EMS) is the alkylating agent that is most commonly employed in crop plants because it frequently induces nucleotide substitutions as detected in numerous genomes.

Methods.

In this study, seeds of the widely consumed Basmati rice variety (Super Basmati, *Oryza sativa* L.) were treated with EMS at concentrations of 0.25%, 0.50%, 0.75%, 1.0%, and 1.25% to broaden its narrow genetic base.

Results.

Sensitivity to a chemical mutagen such as ethyl methanesulfonate (EMS) was determined in the M1 generation. Results in M1 generation revealed that as the levels of applied EMS increased, there was a significant reduction in the germination percent, root length, shoot length, plant height, productive tillers, panicle length, sterile spikelet, total spikelet, and fertility percent as compared to the control under field conditions. All the aforementioned parameters decreased but there was an increase in EMS mutagens in an approximately linear fashion. Furthermore, there was no germination at 1.25% of EMS treatment for seed germination. A 50% germination was recorded between 0.50% and 0.75% EMS treatments. After germination, the subsequent parameters, viz. root length and shoot length had LD_{50} between 0.50% and 0.75% EMS dose levels. Significant variation was noticed in the photosynthetic and water related attributes of fragrant rice. The linear increase in the enzymatic attributes was noticed by the EMS mediated treatments. After the establishment of the plants in the M1 generation in the field, it was observed that LD_{50} for fertility percentage was at EMS 1.0% level, for the rice variety.

Conclusion

Hence, it is concluded that for creating genetic variability in the rice variety (Super Basmati), EMS doses from 0.5% to 0.75% are the most efficient, and effective.

Keywords: Lethal dose, Ethyl methanesulfonate, Rice, Germination, Productivity

Introduction

Nearly half of the world population relies mostly on the rice crop as a primary staple food. An agro-ecological landscape and the associated biodiversity and customer quality choices have also been major contributors to the development of new rice varieties which is leading to more genetic diversification and several varietal groupings (Loko et al., 2021). To ensure food security, it is essential to increase production by utilizing effective techniques for the efficient enhancement of yield (Zaghum et al. 2022). The aromatic local cuisine rice (i.e., pulao or biryani) from the Indian subcontinent known as "Basmati" is made up of one such varietal group and is quite expensive both domestically and abroad. The extra-long, narrow grain, pleasant aroma, and fluffy soft textured Basmati rice variety its origins in the Himalayan foothills which provide the most suitable environment for its growth and its distinguishing features (Hameed et al. 2019; Malabadi et al. 2022). Besides other breeding tools, irradiation (i.e., fast neutrons, γ -rays, & x-rays) and chemical mutagens (i.e., DEB, EMS, & sodium azide) have been frequently used to produce a broad range of functional mutations in rice (Gulfishan et al. 2023). Phenotypic characterization of super basmati using ethyl methanesulfonate (EMS) was carried out by earlier researchers (Hameed et al. 2019). For functional genomics and breeding studies, a large mutant population of coarse variety Katy was developed using EMS (Jia et al. 2019). In earlier studies, the upland rice variety Nagina 22, and the Japonica variety Shengdao 808 had also been used for developing mutants exhibiting tolerance to drought and salinity and natural variation studies (Shang et al. 2021; Zargar et al. 2022).

Mutagens cause point mutations, making them suitable for creating missense and nonsense mutations that would result in functional mutations. Ionizing radiation also causes chromosomal rearrangements and deletions (Le Roux 2019; Singh et al. 2021). Mustard gas, methyl-methanesulfonate (MMS), ethyl-methanesulfonate (EMS), and nitrosoguanidine are all alkylating agents that have diverse effects on DNA (Ramesh et al. 2019). According to Talebi et al. (2012), ethyl-methanesulfonate (EMS) produces mutations by alkylating guanine bases, which results in mismatches with thymine rather than cytosine and triggers transitions from G/C to A/T. EMS can also lead to A/T to G/C conversions through mismatches of 3-ethyladenine or G/C to T/A transversions by 7-ethylguanine hydrolysis (Serrat et al. 2014). The EMS causes point mutations in the rice genome and is one of the most commonly used mutagens in plants due to its potency and ease of application (Upadhyaya et al. 2007).

Since EMS induces an abundance of non-lethal point mutations (genome-wide), a slight mutant population (roughly ten thousand) is abundant to saturate the genome with mutations. The point mutation rate is four

mutations per Mb in Arabidopsis (Kazama et al. 2017). A significant benefit of using a mutagen like EMS in forward genetic screens depends upon its efficacy in a range of organism types (Taheri et al. 2017). In different species, chemical mutagenesis induces a different rate of nucleotide substitutions. In Arabidopsis and maize mutational density was observed per gene (Talebi et al. 2012). EMS was also used in other crops like sugarcane where the calli were mutagenized with 0.5% EMS and exposed to 2% (w/v) PEG-6000 for induction of the osmotic stress (Gadakh et al. 2021). The mutant, dmc, was obtained from EMS treatment in wheat variety Guomai 301 (Li et al. 2021). New approaches have been undertaken in recent years to produce EMS-induced rice varieties at research institutes (Kumawat et al. 2022). The LD_{50} dose is first calculated and then used to determine the best dose for inducing mutations in CR1009 and CR1009 sub1 rice (Khannetah et al. 2021). Thai highland rice (cv. Dawk Pa-yawm and Dawk Kha 50) was subjected to induced mutagenesis using ethyl methane sulphonate (EMS) to create genetic variability (Awais et al., 2019; Unan et al., 2022). By leaving out this stage, the mutagen dose can result in either a high or low mutation frequency (Barr & Fearn 2016; Espina et al. 2018).

Basmati rice has a narrow genetic base and broadening its genetic base using non-basmati rice material may affect its quality attributes. The transgenic approaches have GMO issues. Hence, changing genes in the living cell is not an easy job. The improvement of the CRISPR-Cas9 system in plants is carried out by gene editing which is more specific to gene removal or removing sequences. In CRISPR Cas9 the mutations are also random but often the intended changes are very precise. The removal of sequences/genes may have negative effects on disease resistance, drought, and salinity tolerance. The objective of CRISPR Cas9 is also to develop resistant plants against biotic and abiotic stresses.

In CRISPR Cas9, the bacterial system is used to protect from viruses and replace the mutant/lethal gene with the healthy copy. This can be done by adding the other DNA that carries the desired sequence in cultured cells. In the mutation breeding approach, mutants developed mostly due to deletions in DNA sequences, and no transgenic approach is involved. Like CRISPR Cas9, the cultured cells (Callus) are screened on hygromycin media to conform to the transgenic. Basmati rice being an exportable commodity, the hygromycin resistance is an issue in Basmati rice patenting. The induced mutation has the option to alter one or the other desirable genes without compromising other traits.

Besides, among the conventional breeding and transgenic approaches, induced mutation is the easiest approach that can be used for creating genetic variability without compromising the quality attributes. Inducing genetic diversity in rice by ionizing radiation has been proven to be successful. Understanding the relative biological effectiveness and efficiency of different mutagens is helpful in mutation breeding before the start of any sound breeding program. Many scientists have undertaken several experimental investigations in this regard to identify the most efficient mutagenic method for the induction of desirable features in rice.

This research aims at determining an optimal EMS dose (-50% lethal dose) in comparison to the standard (control). Various EMS concentrations were applied to *Super Basmati* rice (Fragrant Rice) seeds and systematically assessed the survival and lethal doses during germination, seedling lethality, morpho-physio-biochemical, and yield attributes. Based on these observations, we may determine the optimal condition for EMS mutagenesis in the *Super Basmati* rice cultivar improvement against different ecological extremes.

Materials & Methods

Plant material

In this research work a total of 400 seeds of the rice cultivar *Super Basmati* (*Oryza sativa* L. spp.) were selected by collecting from the Plant Breeding and Genetics Division of the Nuclear Institute for Agriculture and Biology (NIAB), Faisalabad, Pakistan.

EMS mutagenesis

Super Basmati seeds were soaked in ultrapure water (-100 mL) up to a height of 5 cm above the seeds and stored at room temperature overnight for 20 hours. The 50 mL of EMS with (v/v)

Comentado [A4]: The deletion of any gene is not necessarily going to have that effect. Detailed knowledge of the function of gene products is necessary to direct editing

Comentado [A5]: In the CRISPR editing system there is the possibility of altering off-target genes. However, the individuals resulting from the edit can be scrutinized to ensure that there are no additional changes. This can consume time and significant financial resources. It is possible that, in this sense, the use of EMS may be a better option.

Comentado [A6]: there are no references

Comentado [A7]: This research aims at determining an optimal EMS dose (-50% lethal dose) in comparison to the standard (control) in order to generate variability, keeping typical characteristics of *Super Basmati* rice. Various EMS concentrations were applied to seeds and systematically assessed the survival and lethal doses during germination, seedling lethality, morpho-physio-biochemical, and yield attributes. Based on these observations, we may determine the optimal dose for EMS mutagenesis in the *Super Basmati* rice cultivar improvement against different ecological extremes conditions.

concentrations (0.25%, 0.50%, 0.75%, 1.0%, and 1.25 %) were added after decanting the ultrapure water (resistivity of 18.2 MΩ.cm @ 25 °C). The seeds were then transferred and rinsed with 100 mL ultrapure water (5 times and 4 minutes each) and 200 mL ultrapure water (4 times, and 15 minutes each), and after that treated seeds were incubated at room temperature for 12 hours. The processed seeds were then washed in continuously running tap water for about 4 hours before being placed in Petri dishes for further analysis (Talebi et al. 2012) (Fig. 1).

Photosynthetic attributes

Photosynthetic rate (A), transpiration rate (E), and stomatal conductance (g_s) were measured on completely lengthened uppermost leaves with a portable photosynthesis system (Infra-Red Gas Analyzer) at a light saturating intensity between 9:00 am to 12:00 noon on a full-sun day. Samples (~5 g) of leaves from each treatment were collected on test tubes containing acetone (85% each sample) were macerated in the same tube. Samples were kept in the dark for 24 hours to allow the extraction of photosynthetic pigments. Tubes were centrifuged for 10 min at 4000 xg at 4°C to remove cellular debris. Supernatants were measured in a spectrophotometer (Halo DB-20/ DB-20S, UK) at 470, 647, and 664.5 nm to measure contents of chlorophyll (Lichtenthaler 1987).

Water related attributes

For the determination of water related attributes, three penultimate leaves of each treatment were harvested at the tillering stage. A pressure chamber was used to determine the leaf water potential. After that leaf samples were frozen and thawed sap was extracted and the osmotic potential was determined using digital Osmoter (Wescor, Logan, UT, USA) (Farooq et al. 2009).

Activities of enzymatic antioxidants

An aliquot of fresh green leaf sample amount was homogenized with 5 mL of 50 mM Tris-HCl buffer (pH 8.0) for CAT and 50 mM KH₂PO₄ buffer (pH 7.0) for POX and APX determination. The homogenate was centrifuged at 5000 rpm for 20 min and the supernatant was then used as enzyme extract. The CAT (EC: 1.11.1.6) activity was assayed as described by Islam et al. (2009). The POX (EC: 1.11.1.7) and APX (EC: 1.11.1.11) activities were assayed as described by Zeng et al. (2011).

Lethal dose study in EMS mutagenesis

In addition to the control, a total of about 40 seeds were planted on filter paper that had been dipped in 5 mL of ultrapure water in Petri plates, following the EMS-induced treatments. Petri plates were then placed at 25°C for 7 days in an incubator. The number of seeds that were grown under controlled conditions was counted and observed after seven days of germination. The germinated seeds from each applied EMS concentration, as compared to the control, were shifted to plastic pots and later in the rice field. In the greenhouse, the seedlings were irrigated with distilled water. After two weeks, the shoot and root lengths were measured using the sandwich blotter technique (Ariman et al., 2014). After sown on the nursery bed, the emergence was recorded for each dose after germination. Parameters such as the height of the plant, panicle length, productive tillers, total spikelet, sterile spikelet, and fertility percent were measured at the physical maturity of rice plants.

Eliminado:

Statistical analysis

For lethal dose determination, the rice variety was treated with five levels of EMS concentrations and then sown in triplicate in a randomized block design. The least significant difference (LSD) test with p-values less than 0.05 was employed to analyze the average variance for all investigated parameters between treated and control plants. The statistical evaluation was carried out using Statistix 8.13 software. Principle component analysis (PCA) was carried out using Minitab-19.

Results

Effect of EMS-induced mutagenesis on germination

The experimental data indicated that different doses of EMS caused variations in the germination of aromatic rice. The seed germination attributes of the control along with the treated seeds of Basmati rice are shown in Table 1. The major differences in the values of seed germination after the EMS treatment at varying doses of 0.25%, 0.50%, 0.75%, 1.00%, and 1.25% were highly significant at the 5% concentration. In all cases, there is an inhibitory effect, but it occurs to different degrees depending on the dose level. In the case of seed germination, data indicate that EMS had a retarding growth effect, or even inhibit it, depending on the dose applied, as compared to the control (Fig. 2). Under the conditions of EMS treatments of 0.25% and 0.50% levels, seeds showed the highest germination percentages, 91.4% & 89.6%, respectively, among all other EMS treatments. Low seed germination percentages were recorded in the higher doses at 0.75% and 1% levels to be 34.4% and 6.9%, respectively, while 1.25% treatment did not register any germination.

Eliminado:

Effect of EMS mutagenesis on seedling growth attributes

The length of the roots and shoots revealed that EMS-induced mutagenesis had a substantial effect on their growth as indicated by the size. According to the measurements and observations, shoot length decreased in proportion to the amount of EMS applied (Table 2 & Fig. 3). It was evident that when the concentration of EMS was increased, the root length decreased as compared to the control. The EMS 0.25% level exhibited the highest shoot length of 5.22 cm as compared to the control (5.44 cm). In other treatments of EMS viz. 0.5%, 1.0%, and 1.25%, a decreasing trend in shoot length of 4.85, 0.29, and 0.07 cm, respectively, were recorded as compared to the control. Among the EMS treatments, 0.25% level exhibited a maximum root length (5.75 cm) than the other treatments of 0.5% EMS (5.16 cm), 0.75% EMS (0.43 cm), and 1% EMS (0.15 cm). At a 1.0% concentration of EMS, the shortest root length was recorded in the experiment. A decreasing trend in the length of shoot and root was observed with the increase in the dose of EMS. When Basmati rice was treated with EMS concentrations greater than 1%, no seed germination was observed for the genotype under consideration.

Effect of EMS mutagenesis on photosynthetic attributes

Various concentrations of EMS treatments significantly affected the photosynthetic attributes of fragrant rice. It was observed that by increasing the concentration of EMS treatments a linear increase was noticed up to 0.75% of EMS treatment. At 1% concentration, there was a decrease in all the photosynthetic attributes that was statistically at par with the 0.25% EMS treatment. The maximum of all the photosynthetic attributes was observed at 1.00% EMS treatment (Table 3).

Effect of EMS mutagenesis on water related attributes

It is observed from the experimental data of the current study that there exists a linear increase in the water related attributes after the EMS mutagenesis. Maximum relative water contents, water potential, and osmotic potential were noticed at 0.75% EMS treatment in the fragrant rice. However, at 1.00% there is a decrease in the water related attributes that was statistically at par with the concentration of 0.25%. A minimum of all the water related attributes was noticed under control conditions (Fig. 4).

Effect of EMS mutagenesis on enzymatic antioxidants attributes

Significant variation was observed in the activities of enzymatic antioxidants by the EMS treatments. A linear increase was observed in all of the activities by the EMS treatments. A minimum activity was noticed at control while the maximum activity was observed at 1.00% EMS treatment. At 1.25% concentration, there was no value because of no germination (Table 4).

Eliminado:

Effect of EMS mutagenesis on phonological and yield contributing attributes

The maximum plant height (Table 5 & Fig. 5) after attaining maturity level was measured to be 104.6 cm

and 105.0 cm in 0.25% EMS treatment and control, respectively. The minimum plant height (94.67 cm) was measured in 1% dose of EMS. In the present study, EMS treatment at the highest concentration (1.25%) has shown an inhibitory effect as compared to the control. Productive tillers, panicle length, and total spikelet (Table 5) showed a maximum length of 3.67, 26.9, and 111.9 cm at 0.25% EMS treatments whereas control ranged as 3.90, 26.9, and 112.9 cm of productive tillers, panicle length, and total spikelet, respectively. However, at a 1.5% EMS level, an inhibitory effect for productive tillers, panicle length, and total spikelet was recorded as compared to the control. It was observed that the proportion of sterile spikelets increased as the applied EMS concentration increased. When Super Basmati was treated with a concentration of 0.25%, the highest value in sterile spikelets (85.2) was observed. Figure 3c indicates that as the applied EMS concentration was increased, fertility decreased. In the control group, the highest fertility rate (13.12%) was observed. When the Super Basmati cultivar was subjected to a concentration of 0.25%, the highest fertility rate (11.48%) was observed. At 1% EMS concentration, the lowest sterile spikelets, and fertility were registered. An EMS treatment above 1% concentration, showed a total inhibition of sterile spikelet, and fertility (Table 6).

Lethal dose effects

An EMS treatment at various concentration levels was evaluated on the aromatic rice variety Super Basmati to determine the LD_{50} based on the germination rate, growth, and yield attributes of rice (Fig. 6). The results obtained in this investigation indicated that the germination and all other measured attributes decreased when the EMS dose was increased. The LD_{50} values for seed germination (0.069%), root length (0.6%), shoot length (0.625%), plant height (1.125%), productive tillers (1.125%), panicle length (1.125%), total spikelet (1.126%), sterile spikelet (1.06%), and productivity (1.05%) for Super Basmati rice variety were carefully determined (Fig. 7).

Discussion

EMS mutagenesis resulted in a major reduction in germination under the prevailing field conditions. As the EMS concentration increased, there was a substantial decrease in seed germination. The EMS has shown to be one of the most potent chemical mutagens as an alkylating agent. According to previous research work, it has been documented that polyploids are more tolerant than diploids (Hernández-Muñoz et al., 2019). The Basmati rice used in the study is also diploid. The percentage reduction in seed germination might have been caused by the influence and impact of mutagens on the meristematic tissues of the seed. The decrease in seed germination at higher dose levels of the mutagens may be attributed to the disturbances at the cellular level with implications at the physiological level.

Earlier research work has shown that in okra (*Abelmoschus esculentus*), germination percentage generally decreased with increasing dose concentrations of gamma rays and the EMS levels (Gupta et al., 2016). Reduced germination percentage with increasing doses of gamma radiation has also been reported in pinus (Ariraman et al., 2014), rye (Khah & Verma 2015), and chickpea plants (Shah et al., 2008). A gradual reduction in germination percentage was also observed with an increase in the concentration of mutagen, reaching more than 50% lethality at 0.5% EMS level in two genotypes of tobacco plants (Dhakshanamoorthy et al., 2010). In this study, seeds of the Super Basmati rice variety were treated with chemical mutagen EMS viz., 0.25%, 0.5%, 0.75%, 1 %, and 1.25% concentrations. In the laboratory germination test, it was observed that an increase in the level of EMS had an overall adverse effect. Similar results have been reported in a previous study of *Capsicum annuum* (Hasan et al. 2022) that seeds treated with 1.5% of EMS dose in M1 generations had the lowest germination percentage (-84%) among all treatments. The germination percentage was found to be profoundly inhibited by EMS treatment in two varieties (Co1 and Co2) of soybean plants (Karthika & Subba, 2006). The mutagenic reaction is more or less linear with the dosage quantity. Plant survival to maturity is dependent on the type and extent of chromosomal damage according to a previous study on radiation mutation (Naaz et al., 2022). Germination inability, plant growth, and survival can be reduced as the occurrence of chromosomal damage increases with growing radiation dose (Sood et al., 2016). Furthermore, genes close to the centromere are more sensitive to mutagenic treatment than genes further apart. Chlorophyll mutants were observed in the EMS treatment

Comentado [A8]: check font size

Eliminado: Productive

Comentado [A9]: This is a report for ornamental plants, it is not for grasses, it should be clarified in the text.

Comentado [A10]: In this sense, compare with what is reported in this paper (Ethyle methane sulphonate (EMS) induced mutagenic attempts to create genetic variability in Basmati rice) would be much more relevant. This was suggested from the first revision of the present manuscript. A previous work "Ethyle methane sulphonate (EMS) induced mutagenic attempts to create genetic variability in Basmati rice (Wattoo et al., 2012)", already reported the effect of EMS on germination and some agronomic traits of two Basmati rice varieties, which are not mentioned in this work. This submitted paper presents some additional aspects evaluated in plants treated with EMS, but it is essential that authors analyze and compare the common results and justify the relevance of the data that may be new, depending on the dose, exposure time and number of individuals analyzed.

group but were uncommon in the **physical mutagen treatment** group (Bado et al., 2015; Chaudhari et al., 2015). The activation of RNA or protein synthesis may be responsible for the stimulating effect of physical mutation on germination. It can happen after the seeds have been processed during the early stages of germination (Zhang et al. 2021). Shoot length is most commonly used as an index to classify and report the biological effects of different physical and chemical mutagens in M1 (Boyane 2015). Shoot length and the dosage of physical or chemical mutagens have been shown to have a linear relationship. Measured data of this study showed that increases in the EMS concentrations caused decreases in shoot length. Our findings also revealed that when the rice variety of Super Basmati was treated with EMS, the shoot length decreased significantly as compared to the control. The concentration of applied EMS had an important impact on the root length of Super Basmati rice. Every subsequent increase in the EMS concentration resulted in a reduction in root length. Enhancement or inhibition of germination, shoot length, and other biological responses are commonly observed in low or high dose treated plants (Deoli & Hasenstein, 2018; Galal & Thabet, 2018).

According to Shelar et al. (2021), a low dose of irradiation induces growth stimulation by either modifying the hormonal signaling network in plant cells or growing the cells' anti-oxidative ability. Plants can easily withstand everyday stress factors such as light intensity and temperature variations in the environment. The cell cycle arrests at the G2/M phase during the somatic cell division and various types of damages in the entire genome have been associated with the high dose treatments (Ahmad et al. 2022; Jan et al. 2012). Variability was assessed in this analysis by the mean values of the shoot and root lengths, both of which decreased as the concentration of EMS increased. **When the radiation amount** is sufficient to reduce rooting percentages, the root lengths do not exceed a few millimeters in size as reported in a physical mutation analysis (Chaudhuri, 2002). After irradiation, seeds are unable to germinate due to metabolic disorders (Sood et al., 2016).

When rice plants are exposed to lower dosages of mutagens, they exhibit defensive responses that involve structural changes in the photosynthetic machinery. Increasing the concentration of EMS enhanced the concentration of photosynthetic attributes in a linear pattern, however, at 1.25% EMS concentration plant growth and development was affected due to poor rate of germination. Maximum chlorophyll content was seen when **Capsicum annuum** was treated with 0.1% EMS for 3 hours, according to (Asif, 2023). Saba and Mirza (2002) reported a **similar** findings by discovering that tomato plants treated with 0.5% EMS for three hours had the maximum chlorophyll content along with other photosynthetic attributes. Enhancement in the water related attributes might be due to the better growth and stay green character of rice plants. However, lower and extremely higher doses could cause a significant change in the DNA of the rice plants, as has been reported for mutagenesis studies in rice (Viana et al., 2019). Except for control and 1.25% EMS concentration, all treatments exhibited a notable improvement in water content, but the 1.00% exhibited a decline in the water related attributes. According to Elyadini et al. (2021), one of the two adaption mechanisms maintaining a high level of tissue elasticity or lowering osmotic pressure can contribute to the maintenance of a relatively high value of the relative water content under EMS treatment leading to a positive effect on the rice plants for improving its overall productivity.

The enzymatic antioxidants are essential enzymes in plant cells that remove H₂O₂ from various organelles like the cytosol and chloroplast to prevent oxidative damage (Zahra et al., 2021). **high APX activity was observed in this study and various researchers have also observed an increase in APX activity during the increased concentrations of EMS treatments** (Abid et al., 2018). Therefore, the production of reactive oxygen species in cells that lack water content causes cell damage, which eventually culminates in cell death (Bali & Sidhu 2019). The balance in the enzymatic antioxidants, whose activity was raised at moderate levels of EMS treatments, is one of the antioxidant systems that regulate oxidative stress through a variety of adaptive ways (Palace et al. 1998). Under higher levels of EMS, enzymatic antioxidant activity was found to be elevated in wheat, as it was in many other crop species (Devi et al. 2012). Cell walls, vacuoles, extracellular spaces, and cytosol, all contain APX. This enzyme, which is known as a stress indicator, has a broad range of phenolic substrate selectivity and is attracted to H₂O₂ than catalase. It can use H₂O₂ to produce phenoxy chemicals, which ultimately polymerize lignin, a component of the cell

Comentado [A13]: what is this "physical treatment"? I understand that you have a control without treatment and different doses of EMS

Con formato: Resaltar

Comentado [A14]: as it has been observed in *Psoralea corylifolia* (Badoe te al 2015) in the second case it is a review (Chaudhari et al 2015) and I cannot find in which other plant species the effect on the chlorophyll content has been demonstrated

Comentado [A15]: this corresponds to the effect on vicia faba treated with silver nanoparticles, not with EMS. Cytological and Molecular Effects of Silver Nanoparticles (AgNPs) on Vicia faba M1 Plants

Comentado [A16]: seed nanopriming technology, this review also describes some of the emerging nano-seed priming methods for sustainable agriculture

This reference is also related to nanoparticles. Perhaps there is some relationship between the effect caused by the nanoparticles and the one generated by EMS. If so, the relationship should be clearly stated in the text. I do not have elements to make this correlation.

In the case of the examples you mention, when the plants are treated with radiation, the relationship due to the mutagenic effects caused seems clearer. In any case, my suggestion is that the clarification be made for each example

Comentado [A20]: this paper is not related to EMS treatment. Indeed, they measure APX activity, but the treatments are for drought stress.

Plants exhibited osmotic adjustment through the accumulation of soluble sugars, proline, and free amino acids and increased enzymatic and non-enzymatic antioxidant activities. After re-watering, leaf water potential, membrane stability, photosynthetic processes, ROS generation, anti-oxidative activities, lipid peroxidation, and osmotic potential completely recovered for moderately stressed plants and did not fully recover in severely stressed plants.

The EMS-treated seeds may develop a mutant basmati rice variety. This is possibly due to the pleiotropic impact of mutated genes or mutations on various genome loci (Muqaddasi & Arif 2012). Several morphological mutations in legume plants have also been identified (Goyal et al. 2019) and few of mutations have been shown to affect multiple attributes. A combination of the elevated amount of dose and the period of treatment resulted in higher seedling death and lower yield in the plant characteristics in the EMS-treated seeds. Similar results were recorded in an experiment of EMS-treated fenugreek seeds, where no callus cultures were developed when treated with EMS levels above 1% (Basu et al., 2008). In this analysis, LD_{50} values for yield contributing traits included the plant height (1.125%), productive tillers (1.125%), panicle length (1.125%), complete spikelet (1.126%), sterile spikelet (1.06%), and fertility (1.05%) which were found in seeds treated with 0, 0.25, 0.5, 0.75, 1, and 1.25 percent EMS, resulting in an inverse association between all of these yielding traits (Kozgar et al. 2011). The efficacy of the current study decreased as the concentration of EMS increased. This observation was also confirmed by the findings in black gram (Usharani & Kumar 2015), chickpea (Singh et al. 2015) and cowpea plants (Nair & Mehta 2014).

Eliminado: ,

The variation in LD_{50} for the Super Basmati rice variety at the different EMS (%) concentrations has been observed in mutation studies, and it is thought to be mainly due to the biological material, scale, maturity, hardness, and moisture content at the time of exposure of breeding material (Thakur et al., 2020). There is sufficient evidence that the radiation-induced sterility of M1 panicles is passed on to subsequent generations (Jyothilekshmi, 2012). Physiological damage induces a significant portion of sterility, which is not passed on to the next generation. It is found in this research work that with the increasing doses of mutagen treatments, induced panicle sterility increased the panicle sterility. These findings are consistent with those of previous researchers (Siddiqui & Singh 2010; El-Degwy, 2013) who found that gamma-ray treatment caused rice plants to become highly sterile. In determining the yield potential of these mutants, it will be vital to analyze the heritability in a multi-location yield trial that incorporates suitable experimental design to assess whether these mutations will perform consistently across different environments.

Conclusions

Physicochemical mutagenesis has been employed to produce genetic variability in crops including rice plants. The ethylmethane sulfonate (EMS) induced mutagenesis is a promising exploratory tool to search for novel players for improving agronomic and yield contributing traits. Germination, seedling growth, and yield attributes were significantly influenced by variations in EMS concentration treatments. There was no germination observed upon the application of a 1.25% concentration of EMS treatment for seed germination and 50% germination was recorded between EMS 0.50% and EMS 0.75% treatments. After the cultivation of rice plants of the M1 generation in the field, it was observed that LD_{50} for fertility occurred at EMS 1.0% for the investigated rice variety. The EMS treatment demonstrated a negative biological influence such as reduced germination and abnormal seedling development of Basmati rice plants. It is, therefore, concluded that for creating genetic variability in the rice variety of Super Basmati, the EMS doses from 0.5% to 0.75% are more useful and effective for improving the overall performance of fragrant rice. Furthermore, mutants with yield related value-added traits will be available for the scientific community for advanced level research and will also serve as a public genetic resource for development and breeding programs.
