## Abstract

**Background.** P is regarded as one of the major limiting factors in grassland ecosystems. Soil available phosphorus deficiency could affect soil extracellular enzyme activity, which plays an essential role in microbial metabolism. Yet, it is still unclear how soil available phosphorus affects soil extracellular enzyme activity and microbial nutrient limitation of desert grassland in the context of climate warming.

**Methods.** The study carried out a short-term open-top chambers (OTCs) experiment in desert steppe to examine the effects of warming, P addition and their interaction on soil properties, the activities of soil extracellular enzyme s and stoichiometries.

**Results.** The findings demonstrated that soil acquisition enzyme stoichiometry of C: N: P was 1.2:1:1.5 in this experiment region, which deviated from the global mean scale (1:1:1). Warming increased soil AN ( ammonium nitrogen and nitrate nitrogen) contents, decreased MBC (microbial biomass carbon) and MBN (microbial biomass nitrogen). Phosphorus addition raised the soil available phosphorus contents and MBP (microbial biomass phosphorus). Soil extracellular enzyme activities and stoichiometries in desert grassland are largely impacted by soil AN, MBC: MBP, and MBN: MBP. These results revealed that the changes of soil available nutrients and stoichiometries induced by short-term warming and P addition could influence soil microbial activities and alleviate soil microbial carbon and phosphorus limitation. Our findings highlight the critical role played by soil available phosphorus in regulating soil extracellular enzyme activity and microbial nutrient limitation of desert grassland. It will be better to comprehend the microbiological mechanisms underlying these events with further research on the soil microbial communities.

## 36 **Abstract**

37 **Background.** P is regarded as one of the major limiting factors in grassland ecosystems. Soil  
38 available phosphorus deficiency could affect soil extracellular enzyme activity, which plays an  
39 essential role in microbial metabolism. Yet, it is still unclear how soil available phosphorus  
40 affects soil extracellular enzyme activity and microbial nutrient limitation of desert grassland in  
41 the context of climate warming.

42 **Methods.** The study carried out a short-term open-top chambers(OTCs) experiment in desert  
43 steppe to examine the effects of warming, P addition and their interaction on soil properties, the  
44 activities of soil extracellular enzymes and stoichiometries.

45 **Results.** The findings demonstrated that soil acquisition enzyme stoichiometry of C: N: P was  
46 1.2:1:1.5 in this experiment region, which deviated from the global mean scale (1:1:1). Warming  
47 increased soil AN (ammonium nitrogen and nitrate nitrogen) contents, decreased MBC  
48 (microbial biomass carbon) and MBN (microbial biomass nitrogen). Phosphorus addition raised  
49 the soil available phosphorus contents and MBP (microbial biomass phosphorus). Soil  
50 extracellular enzyme activities and stoichiometries in desert grassland are largely impacted by  
51 soil AN, MBC: MBP, and MBN: MBP. These results revealed that the changes of soil available  
52 nutrients and stoichiometries induced by short-term warming and P addition could influence soil  
53 microbial activities and alleviate soil microbial carbon and phosphorus limitation. Our findings  
54 highlight the critical role played by soil available phosphorus in regulating soil extracellular  
55 enzyme activity and microbial nutrient limitation of desert grassland. It will be better to  
56 comprehend the microbiological mechanisms underlying these events with further research on  
57 the soil microbial communities.

## 58 **Introduction**

59 Phosphorus (P), one of the most significant mineral elements, is crucial for plant development,  
60 substance synthesis and energy metabolism (Sharma et al.,2020), Yet, due to the effects of  
61 climate change, human activities, land use patterns and other reasons, there has been a severe  
62 shortage of soil available P worldwide (Hinsinger, 2001; Hou et al., 2020). P has evolved into a  
63 major limiting factor for plant growth in grassland ecosystems (Du et al., 2020), which may have  
64 negative effects on primary productivity and other ecological processes (Tang et al.,2018; Hou et  
65 al.,2020). Since 1850-1900, the temperature of the atmosphere has risen by around 1.1 °C, and it  
66 is predicted to reach or exceed 1.5-2.0 °C in the future (IPCC, 2021). The availability of nutrients  
67 in the soil may change as a result of climate warming (Feike et al.,2012; Hu et al., 2022), which  
68 requires soil microbes to secrete extracellular enzymes in response to the variation of soil  
69 nutrients (Raiesi and Salek-Gilani,2018; Cui et al.,2019a), this is because the activity of soil  
70 extracellular enzymes regulates the decomposition of soil organic matter and the cycling of  
71 nutrients, which in turn affects the function of ecosystem services (Güsewell, 2004; Hu et al.,  
72 2016). Soil extracellular enzyme secretion is frequently the rate-limiting step of microbial  
73 metabolism (Nannipieri et al.,2018). In this process, the temperature affects the soil microbial  
74 activity (Zi et al.,2018). According to the studies, global warming has the potential to change soil  
75 available phosphorus by altering mean annual temperature and precipitation(Hou et al.,2018),

76 and also have an impact on phosphorus fixation, mineralization, and weathering by indirectly  
77 affecting plant growth and soil microbial community structure (Delgado-Baquerizo et al.,2013).  
78 Evaluating the degree of nutrient availability and limitation of the microbial environment can be  
79 achieved by analyzing soil C, N, and P acquisition enzyme activities and stoichiometries  
80 (Moorhead et al., 2013; Dong et al., 2019).

81 The previous findings demonstrated that climate change can increase the availability of  
82 nutrients by accelerating the microbial breakdown of soil organic matter (Bardgett et al., 2008).  
83 The demand for carbon and phosphorus from microbes may change as a result of soil short-term  
84 warming, leading to greater microbial phosphorus limitation (Zheng et al.,2020). The addition of  
85 P enhanced the soil available phosphorus, reduced phosphorus limitation, and increased carbon  
86 sequestration (Manzoni et al.,2012; Wang et al., 2022). P addition had both enhancing and  
87 inhibitory impacts on the soil extracellular enzyme activity (Jing et al.,2016; Wang et al., 2020a),  
88 even the input rates of various phosphorus fertilizers affected soil acquiring enzyme activities  
89 (Waring et al.,2014; Tian et al.,2016). These findings imply that potential mechanisms  
90 influencing soil extracellular enzyme activity and microbial metabolism induced by soil  
91 available P in the context of climate change are controversial.

92 A typical fragile grassland ecosystem, the desert steppe is especially vulnerable to climate  
93 change (Zuo et al.,2020), which is important to sustain ecological security and socioeconomic  
94 development (Kang et al.,2007). The degradation of desert grasslands and the decline of  
95 ecosystem stability and service functions may be driven by climate change, overgrazing, and  
96 unreasonable exploitation (Reynolds et al.,2007; Deng et al., 2014; Zhang et al.,2019). Given the  
97 importance of the soil available nutrients for primary production and other ecological processes  
98 in grassland ecosystems (Tang et al., 2018), understanding the relationship between soil  
99 available phosphorus, soil extracellular enzyme activity, and its stoichiometry under warming  
100 conditions can help provide insight into the role of soil available phosphorus in controlling  
101 ecological processes, which is crucial to actively respond to climate warming and develop  
102 effective conservation strategies for desert grassland (Liu et al.,2017; Wang et al.,2021). Here,  
103 we set up a field experiment to investigate the response of soil extracellular enzyme activity and  
104 its stoichiometry to warming and P addition in desert grassland, we sought to address the  
105 following two issues: ( i ) how soil extracellular enzyme activities, microbial nutrient limitation  
106 reacts to short-term warming and P addition; and ( ii ) what are the major factors affecting soil  
107 extracellular enzyme activities and stoichiometries. Based on the previous studies (Waring et  
108 al.,2014; Zheng et al., 2020), we hypothesized that ( i ) the degree of nutrient limitation of soil  
109 microorganisms was closely related to the content of soil available phosphorus; ( ii ) warming  
110 and P addition would significantly reduce soil extracellular enzyme activity in desert grassland.

## 111 **Materials & Methods**

### 112 **Study site**

113 The experiment was conducted on a desert steppe in Eastern Yanchi County (37°04'-38°10' N,  
114 106°03'-107°04' E), Ningxia Hui Autonomous Region, northwest China. It is located on the  
115 southwest edge of the Mu Us Desert, which has a semiarid continental monsoon climate.

116 According to meteorological data from the Yanchi Meteorological Station, the average annual  
117 temperature is 8.8°C, and the average annual precipitation is 298.15mm, with the majority of the  
118 precipitation falling between July and September (1980-2021). The habitat type is the desert  
119 steppe. The soil type is classified as Arenosol (IUSS, 2015), with 4.12 g·kg<sup>-1</sup> of soil organic  
120 matter, 0.40 g·kg<sup>-1</sup> of total nitrogen, 0.32 mg·kg<sup>-1</sup> of total phosphorus, 2.30 mg·kg<sup>-1</sup> of available  
121 phosphorus, and pH 8.57. The dominant species in the region are *Agropyron mogolicum*,  
122 *Lespedeza potaninii*, *Caragana korshinskii*, *Stipa bungeana*, and *Polygala tenuifolia* Willd.

### 123 **Experimental Design**

124 We conducted a randomized split-plot design with two temperature treatments (CK, control; W,  
125 warming) as the main plot and three P addition levels (0 g·m<sup>-2</sup>·yr<sup>-1</sup>, 5 g·m<sup>-2</sup>·yr<sup>-1</sup>, and 10 g·m<sup>-2</sup>·yr<sup>-1</sup>)  
126 as the subplot in April 2022. There were six treatments: P<sub>0</sub>, P<sub>5</sub>, P<sub>10</sub>, WP<sub>0</sub>, WP<sub>5</sub>, and WP<sub>10</sub>, each  
127 replicated four times, for a total of 24 treatment plots. A PVC sheet was put into the soil at a  
128 depth of 0.8 m to divide each subplot from the main plot, which was spaced 3 m apart to provide  
129 a buffer zone. The phosphorus fertilizer was supplied by triple superphosphate [Ca (H<sub>2</sub>PO<sub>4</sub>)  
130 <sub>2</sub>·H<sub>2</sub>O], which was evenly distributed to the treatment plots before rainfall from early June to  
131 August. Although the rate of phosphorus fertilizer input in this study is higher than the rate at  
132 which phosphorus is deposited in the atmosphere of northern China (Zhu et al., 2016), it meets  
133 with the current agricultural fertilization in China (Cui et al.,2020; Guo et al., 2022).

134 Based on the meteorological monitoring of the study site from 1980 to 2021 (Figure S1) and  
135 the existing research foundation of the team (Ma et al.,2019; Ma et al.,2021), we modified the  
136 experimental warming device. OTCs (Open Top Chambers) were used as a passive temperature  
137 rise device in this investigation. The stainless steel and high-transmittance glass material (5mm  
138 thick) were used to construct a regular octagonal prism structure, which has a substrate area of  
139 5.6 m<sup>2</sup> and a vertical height of 1.8 m. They were installed in the sample plot permanently to  
140 avoid disruption. The air and soil temperatures at 15cm above and below ground were  
141 automatically recorded every half-hour using HOBO MX2302A and HOBO MX2201 data  
142 loggers, respectively (Onset Computer Corporation, Bourne, Massachusetts, USA).

### 143 **Soil sampling and measurements**

144 Three soil cores (5 cm in diameter, 15 cm in depth) were collected randomly from each plot after  
145 removing any surface debris on August 25, 2022. These soil samples were cleaned of plant roots,  
146 stone, or other pollutants, and manually homogenized to one composite sample, then returned to  
147 the laboratory immediately. The soil was divided into two parts, one of which was air-dried and  
148 sieved through a 2 mm mesh to measure soil organic carbon (SOC), total nitrogen (TN), total  
149 phosphorus (TP), and available phosphorus (AP). The other of which was stored at 4 °C to  
150 measure soil soluble organic carbon (DOC), ammonium nitrogen (NH<sub>4</sub><sup>+</sup>-N), nitrate nitrogen  
151 (NO<sub>3</sub><sup>-</sup>-N), microbial biomass, and soil C-, N-, P- acquiring enzyme activities.

152 Soil moisture content (SMC) was determined by oven-drying the soil at 105°C for 48 hours. A  
153 PHS-3E glass pH electrode (Leici, Shanghai, China) was used to measure the pH of the soil in a  
154 suspension of air-dried soil and distilled water (1:5, w/v) (Anderson and Ingram, 1993). A TOC  
155 analyzer was used to measure the soil DOC concentration (Vario TOC, Elementar, Hanau,

156 Germany). Soil available nitrogen ( $\text{NH}_4^+\text{-N}$  and  $\text{NO}_3^-\text{-N}$ ) was determined by the KCl extraction  
 157 method with continuous flow analyzer; AP was determined by  $\text{NaHCO}_3$  extraction with  
 158 molybdenum antimony anti-colorimetric method; Soil SOC and TN were determined by  
 159 potassium dichromate external heating method and  $\text{H}_2\text{SO}_4\text{-H}_2\text{O}_2$  digestion with Kjeldahl method;  
 160 Soil TP was determined by  $\text{HClO}_4\text{-H}_2\text{SO}_4$  digestion with molybdenum antimony anti-  
 161 colorimetric method (Nelson, 1996). Microbial biomass (MBC, MBN, MBP) was extracted and  
 162 analyzed by chloroform fumigation (Brookes et al., 1985; Vance et al., 1987), respectively.

### 163 **Soil enzyme extraction and vector analysis**

164 Soil C ( $\beta\text{-1,4-glucosidase}$ , BG), N (leucine aminopeptidase, LAP, and  $\beta\text{-1,4-N-acetylglucosa}$   
 165  $\text{minidase}$ , NAG), and P acquisition enzyme (alkaline phosphatase, ALP) activities were  
 166 determined using a modified standard fluorescence technique (Saiya-Cork et al., 2002; German  
 167 et al., 2011). Soil extracellular enzyme activity (EEA) was expressed in units of  $\text{nmol g}^{-1} \text{h}^{-1}$   
 168 (Sinsabaugh et al., 2008; Sinsabaugh et al., 2009; Waring et al., 2014). The ratios of C, N, and P  
 169 acquisition enzymes were calculated by the following formulae to determine soil extracellular  
 170 enzyme stoichiometry (EES), respectively. Scatter plots of soil ecoenzymatic stoichiometry were  
 171 used to identify microbial resource-limited (Hill et al., 2012; Jiang et al., 2022).

172 Soil e C: N =  $\ln(\text{BG}) / \ln(\text{LAP} + \text{NAG})$

173 Soil e C: P =  $\ln(\text{BG}) / \ln(\text{ALP})$

174 Soil e N: P =  $\ln(\text{LAP} + \text{NAG}) / \ln(\text{ALP})$

175 Soil C, N, and P -acquiring enzyme stoichiometries were assessed using vector analysis.

176 Vector length and vector angle were calculated by the following formulae, respectively  
 177 (Moorhead et al., 2016). Limitations on N and P are shown by vector angles of less than  $45^\circ$  and  
 178 greater than  $45^\circ$ , respectively, while a relative carbon limitation is shown by vector length.

179 Relative C limitation = Vector Length =  $\sqrt{[\ln(\text{BG}) / \ln(\text{LAP} + \text{NAG})]^2 + [\ln(\text{BG}) / \ln(\text{ALP})]^2}$

180 N/P limitation = Vector angle ( $^\circ$ ) = Degrees {ATAN2 $[\ln(\text{BG}) / \ln(\text{ALP}), \ln(\text{BG}) / \ln(\text{LAP} + \text{NAG})]$ }

### 181 **Statistical analyses**

182 A two-way analysis of variance using a split-plot design was carried out to investigate the effects  
 183 of warming, P addition, and their interaction effects on soil extracellular enzyme activity and  
 184 stoichiometries of desert grassland. One-way ANOVA was used to compare the differences in  
 185 soil properties, soil extracellular enzyme activity, and stoichiometries of the different treatments.  
 186 Significant differences were tested using Duncan's multiple comparison tests ( $P < 0.05$ ), and the  
 187 data for soil enzyme activity had been transformed using a natural logarithm before statistical  
 188 analysis. Before performing an ANOVA, all data were tested for normality of the residuals and  
 189 homogeneity of variances in SPSS 25.0 for Windows (SPSS Inc., Chicago, Illinois, USA).

190 Pearson correlation analysis was used to determine the association between soil characteristics,  
 191 microbial biomass and their stoichiometric. Mantel test was used to explore the correlation  
 192 between carbon, nitrogen, and phosphorus acquisition enzyme activities and soil environmental  
 193 factors. RDA (redundancy analysis) was used to explore the corresponding relationships of soil  
 194 properties, microbial biomass, and extracellular enzyme activity in Canoco 5.0. For the graphics,

195 R 4.2.3 and Origin 2022 (Origin Laboratory Corporation, Northampton, MA, USA) were  
196 applied.

## 197 **Results**

### 198 **Soil temperature and soil moisture content**

199 OTCs had the anticipated warming effect in all temperature-increased treatment plots (Fig. 1),  
200 with an average increase of 1.17°C in air temperature 15cm above the ground and 0.65°C in soil  
201 temperature 15cm below ground. Warming considerably decreased soil moisture content by  
202 13.67%. While P addition significantly increased SMC by 11.20% and 19.52% at P<sub>5</sub> and P<sub>10</sub>,  
203 respectively. Soil moisture content was not significantly affected by warming × P addition (Table  
204 1).

### 205 **Soil properties**

206 No significant effects of SOC, TN, or TP by warming (Table. 1). P addition had distinct effects  
207 on SOC under different P addition rates, experiencing a decline of 8.02% at P<sub>5</sub> and an increase of  
208 2.44% at P<sub>10</sub>. P addition significantly increased TP and decreased TN. Warming × P addition  
209 resulted in a rise of SOC and TP. As for TN, WP<sub>10</sub> decreased by 4.48%, while WP<sub>5</sub> grew by  
210 13.43%. Warming and P addition did not significantly affect SOC: TN, but decreased SOC: TP.  
211 Warming × P addition increased SOC: TP at WP<sub>5</sub> while lowering it by 22.59% at WP<sub>10</sub>. Soil  
212 TN: TP decreased by 2.58%, and 29.38% at WP<sub>5</sub> and WP<sub>10</sub>, respectively.

213 The soil pH was not significantly affected by warming, P addition, and their interactions  
214 (Table 1). P addition and warming both lowered soil DOC contents, but their interaction effects  
215 significantly increased DOC 12.22% and 15.06% at WP<sub>5</sub> and WP<sub>10</sub>, respectively. Warming and  
216 warming × P addition significantly increased the AN content. P addition decreased AN by 6.67%  
217 at P<sub>5</sub> and did not change at P<sub>10</sub>. The addition of P had a considerable impact on available P  
218 content, and the higher the rate of P addition, the greater the increase in soil available P content.  
219 Nevertheless, there was no discernible influence of available P by warming. Warming and P  
220 addition decreased DOC: AN. Warming × P addition significantly affected DOC: AN, with  
221 33.05% decrease in WP<sub>5</sub> and no significant difference in WP<sub>10</sub>. P addition and warming × P  
222 addition had a significant negative impact on DOC: AP and AN: AP.

### 223 **Soil microbial biomass and their stoichiometry**

224 Compared to the control plots (P<sub>0</sub>), all of the treatments led to a reduction in MBC and MBN  
225 (Figs. 2A and 2B). Warming and P addition did not significantly affect MBC and MBN, but  
226 their interaction significantly decreased them. MBP responded differently from MBC and MBN  
227 (Fig. 2C), warming lowered MBP by 9.01%, P addition and warming × P addition considerably  
228 increased MBP. Ratios of MBC: MBN, MBC: MBP, and MBN: MBP were significantly reduced  
229 by warming and P addition. Warming × P addition increased MBC: MBN (Fig. 2D) and a  
230 substantial decrease in MBC: MBP (Fig. 2E) and MBN: MBP (Fig. 2F).

### 231 **Soil enzyme activity and their stoichiometry**

232 Soil BG was significantly lowered by warming, P addition, and the effects of their interaction  
233 (Fig.3A). As for warming × P addition, the activity of BG at WP<sub>5</sub> was higher than that at WP<sub>10</sub>.  
234 LAP+NAG was significantly decreased by P addition (Fig.3B), but not significantly affected by

235 warming and their interaction effects. Soil ALP was significantly reduced by warming, P  
236 addition, and warming  $\times$  P addition (Fig.3C). Warming and P addition reduced ln (BG): ln  
237 (LAP+NAG) (Fig.3D), while demonstrating a different trend by Warming  $\times$  P addition, rising by  
238 4.10% at WP<sub>5</sub>, and falling by 13.93% at WP<sub>10</sub>. Regarding ln (BG): ln (ALP) increased at WP<sub>5</sub>  
239 (Fig. 3E), with no significant impacts from other treatments. Warming, P addition and the  
240 interaction effects raised ln (LAP+NAG): ln (ALP) (Fig.3F). In addition, a significant correlation  
241 between BG, NAG+LAP, and ALP activity was also discovered (Fig. 4).

#### 242 **Vector analysis**

243 All the treatments were over the 1:1 line (Fig. 5A), which showed that microbial nutrients were  
244 severely phosphorus limited. Warming, P addition, and their interaction effects reduced vector  
245 angle (Fig. 5B). Vector length and vector angle were decreased as a result of warming and P  
246 addition (Figs. 5C and 5D). Warming  $\times$  P addition increased vector length by 11.64% at WP<sub>5</sub>  
247 and decreased by 7.53% at WP<sub>10</sub>.

#### 248 **Relationships between soil properties and soil extracellular enzyme activities**

249 Pearson correlation showed a significant relationship between soil AP and DOC: AP, AN: AP,  
250 MBN: MBP, MBC: MBP. Soil SMC content was significantly related to DOC: AP, AN: AP.  
251 Mantel correlation analysis showed that soil total nutrients and stoichiometry had no significant  
252 effects on soil EEAs and EES. However, a positive link between soil C and P acquisition enzyme  
253 activities and soil available nutrients, microbial biomass, and their stoichiometry was observed,  
254 soil N acquisition enzyme activity was closely related to DOC: AN, DCO: AP, and MBP. (Fig.  
255 6). By using a redundancy analysis, we further examined the connection between the soil  
256 available nutrients, soil EEAs, EES, and vectors (Fig.7). The results revealed that the important  
257 factors affecting soil EEAs and EES were AN, MBC: MBP, and MBN: MBP. There had a  
258 significant positive correlation between AN and e C: P. e N: P was positively correlated with AP.  
259 MBC was positively correlated with e C: N. Vector length was positively correlated with AN,  
260 while vector angle was significantly negatively correlated with available P (Fig. 7).

#### 261 **Discussion**

##### 262 **Short-term warming**

263 In this study, we conducted a field experiment to investigate the effects of short-term warming  
264 and P addition on the soil extracellular enzyme activity and stoichiometries. Short-term warming  
265 increased soil AN content (Table 1), and reduced microbial biomass C and N (Fig.2). Soil C-, N-  
266 , and P-acquiring enzymes were decreased by warming (Fig. 3), which was consistent with our  
267 hypotheses. No significant effect on the soil total nutrients and stoichiometries by warming  
268 (Table 1). Correlation analysis and redundancy analysis revealed a significant positive  
269 correlation between soil EEAs and soil available nutrients, microbial biomass and their  
270 stoichiometry (Figs. 6 and 7), these results were in keeping with the previous studies (Cui et al.,  
271 2021; Li et al., 2022b). Further research on soil microbial communities of desert grassland is  
272 required to better understand the exact microbiological mechanisms by which microbial biomass  
273 controls the soil extracellular enzyme activity.

274 Soil moisture content may also affect soil EEA (Allison and Treseder,2008; Li et al., 2022a).  
275 Warming considerably decreased SMC in our study (Table 1), however, SMC had no significant  
276 impact on soil EEAs and EES (Figs. 6 and 7), and it was not a limiting factor for soil EEA. The  
277 experiment demonstrated that soil microorganisms may adapt to dry, infertile soil conditions by  
278 adjusting soil extracellular enzyme activity in response to their demands and the surrounding  
279 environment (Gong et al.,2015; Wang et al.,2017). Meanwhile, we discovered that warming  
280 slightly raised  $\ln(\text{BG}) : \ln(\text{ALP})$  and  $\ln(\text{LAP+NAG}) : \ln(\text{ALP})$ , decreased  $\ln(\text{BG}) : \ln$   
281  $(\text{LAP+NAG})$  (Fig. 3), vector length and vector angle (Fig. 5), it is likely because warming  
282 reduced the soil microbial biomass C and N, and consequently influenced the secretion of C- and  
283 N-acquiring enzymes to adapt to environmental changes (Turner and Wright, 2014). Taken  
284 together, short-term warming changed the activities of soil microbial in desert steppe.

### 285 **Phosphorus addition**

286 Soil phosphatases typically showed higher activity in P-limited ecosystems, and soil C and N-  
287 acquiring enzyme activity reflects microbial demand for energy and nutrients (Turner and  
288 Wright, 2014). In our study, P addition lowered soil extracellular enzyme activities (Fig. 3),  
289 which had a great impact on the activity of the P acquisition enzyme (Marklein and  
290 Houlton,2012; Shi et al.,2021). P addition significantly promoted the soil total P, available P and  
291 microbial biomass P content while concurrently reducing DOC, AN, MBC, and MBN contents  
292 (Table 1, Fig. 2). Varying alterations were found in MBC, MBN, and MBP, suggesting that soil  
293 microorganisms may preferentially fix P (Bünemann et al., 2012), which affected the  
294 stoichiometries of soil microbial biomass. Correlation analysis demonstrated a negative  
295 correlation between soil C-, P- acquiring enzyme activity and available P, MBP (Fig. 6) . The  
296 relationship is most likely explained by the fact that P addition increased plant growth and  
297 nutrient uptake while reducing the number of nutrients available for the synthesis of soil  
298 enzymes(Wang et al.,2008). Yet, contrary to the results of some research, this might be  
299 influenced by the factors like the rate of P addition, type of ecosystem and study site (Colvan et  
300 al,2001; Tian et al., 2016; Wang et al., 2020b).

301 In terms of soil extracellular enzyme stoichiometry,  $\ln(\text{BG}) : \ln(\text{LAP+NAG})$  decreased by P  
302 addition, whereas  $\ln(\text{BG}) : \ln(\text{ALP})$  and  $\ln(\text{LAP+NAG}) : \ln(\text{ALP})$  increased (Fig. 3), suggesting  
303 that P addition decreased microbial demand for carbon and soil microbial demand for alkaline  
304 phosphatase production costs in phosphorus-limited soils, and also affects microbial activity  
305 associated with C and N cycling enzymes(Allison et al., 2010). P addition decreased vector  
306 length and vector angle (Fig. 5), demonstrating that P addition can alleviate both the soil  
307 microbial carbon and phosphorus limitation in desert grassland, the result confirmed our  
308 hypothesis that soil microbial nutrient limitation of desert grassland is closely related to soil AP  
309 content.

### 310 **The interactive effects of short-term warming and P addition**

311 In this study, warming  $\times$  P addition significantly reduced soil EEAs (Fig. 3). As for C- acquiring  
312 enzyme activity,  $\text{WP}_5$  was higher than  $\text{WP}_{10}$ , which may be related to the significant increase in  
313 soil DOC and AN content. This, in turn, may have caused the low level of  $\text{P}_5$  addition rate to

314 secrete more C and N acquisition enzymes at higher temperatures, increasing microbial carbon  
315 and nitrogen demand (Fig. 2). At WP<sub>10</sub>, however, there were less available carbon and nitrogen  
316 in the soil, and fewer C- acquiring enzymes are secreted by the microorganisms. WP<sub>10</sub> was  
317 consistently slightly higher than WP<sub>5</sub> throughout the changes in N-, and P-acquiring enzyme  
318 activities, suggesting that the amount of available phosphorus may be a vital factor (Table 1). P-  
319 acquiring enzymes were most significantly impacted by warming × P addition (Fig. 3) . It  
320 showed a negative feedback relationship between high available phosphorus content and soil  
321 EEA (Allison et al., 2007). The positive connection between the activities of the BG,  
322 LAP+NAG, and ALP indicates that these soil enzymes changed significantly under experiment  
323 warming and P addition (Fig. 4), and it further illustrates that the microbial acquisition to C, N,  
324 and P was altered. About soil EES, warming × P addition resulted in a reduction of ln (BG): ln  
325 (ALP) and ln (LAP+NAG): ln (ALP), increased ln (BG): ln (LAP+NAG) at WP<sub>5</sub> and declined at  
326 WP<sub>10</sub> (Fig. 3). Combining the results of the redundancy analysis and correlation analysis, the  
327 primary factors that influenced the soil EEAs and EES were the soil AN, MBC: MBP, and MBN:  
328 MBP. It can be shown that the interaction between warming and P addition had an impact on soil  
329 physicochemical properties, which altered the stoichiometry of soil extracellular enzymes (Zheng  
330 et al.,2015; Zhang et al.,2018).

331 Additionally, the natural log ratio of soil C-N-P- acquiring enzymes in this study was 1.2:1:1.3  
332 (Table S1), which differs from the global mean scale of 1:1:1 (Sinsabaugh et al., 2009),  
333 demonstrating that desert grassland in the study region was largely C and P limitation. This is  
334 partially consistent with the findings of the previous study, demonstrating that desert grassland  
335 was severely P-limited in the temperate grassland of northern China (Peng and Wang, 2016).  
336 The ratio of soil C: N: P acquisition enzymes adjusted to 1.3:1:1.2 at WP<sub>5</sub>, it is shown that a low  
337 phosphorus addition rate causes both soil microbial carbon and phosphorus limitation in the  
338 region, while the addition of P<sub>10</sub> alleviated it. Also, previous research had revealed that adding P  
339 may boost soil microbial nitrogen demand, and lead to an increase in N-acquiring enzyme  
340 activity (Wang et al., 2020b). Nevertheless, it did not occur in our study, and this issue may need  
341 to be confirmed by further research. Vector analysis, however, revealed that relative carbon  
342 limitation increased at WP<sub>5</sub> and reduced at WP<sub>10</sub>. As for phosphorus limitation, a higher level of  
343 phosphorus addition rate (P<sub>10</sub>) was beneficial to alleviate phosphorus limitation in the region.  
344 Warming × P addition changed the soil available nutrient contents and their stoichiometries,  
345 while soil nutrient stoichiometry influences microbial C, N, and P metabolism by regulating soil  
346 elemental balance(Cui et al., 2019b). In this process, the secretion of soil microbial enzymes in  
347 P-deficiency areas of desert grassland was stimulated to adapt to nutrient limitation (Schimel et  
348 al.,2007; Xiao et al.,2018). From the above results, in this study, soil available nutrients,  
349 microbial biomass, and their stoichiometry are the key factors contributing to microbial nutrient  
350 limitation in desert grassland.

## 351 **Conclusions**

352 In this study, we investigated how soil C, N, and P acquisition enzyme activities and  
353 stoichiometries responded to short-term warming and P addition in desert grassland. The results

354 showed that warming did not affect soil available P but altered soil AN, MBC, and MBN. P  
355 addition significantly raised soil available phosphorus contents, which had positive effects on the  
356 activities of BG, LAP+NAG, and ALP. For the different rates of P addition, P<sub>10</sub> was preferable  
357 to P<sub>5</sub> for eliminating the relative carbon and phosphorus limitation. Warming and P addition  
358 slightly raised ln (BG): ln (ALP) and ln (LAP+NAG): ln (ALP), decreased ln (BG): ln  
359 (LAP+NAG). About the interaction of warming and P addition, resulting in a reduction of ln  
360 (BG): ln (ALP) and ln (LAP+NAG): ln (ALP), increased ln (BG): ln (LAP+NAG) at WP<sub>5</sub> and  
361 declined at WP<sub>10</sub>. The primary factors that influenced the soil EEAs and EES were the soil AN,  
362 MBC: MBP, and MBN: MBP. In conclusion, Short-term warming, P addition, and their  
363 interaction significantly affected soil extracellular enzymes and stoichiometries, which in turn  
364 changed microbial resource acquisition techniques in desert steppe. More extensive research on  
365 soil microbial communities is required to confirm the potential role that soil available  
366 phosphorus may play in actively adapting to global warming and microbial nutrient constraint.

**Table 1** (on next page)

Warming, P addition and their interaction effects on soil properties, nutrients contents and stoichiometries.

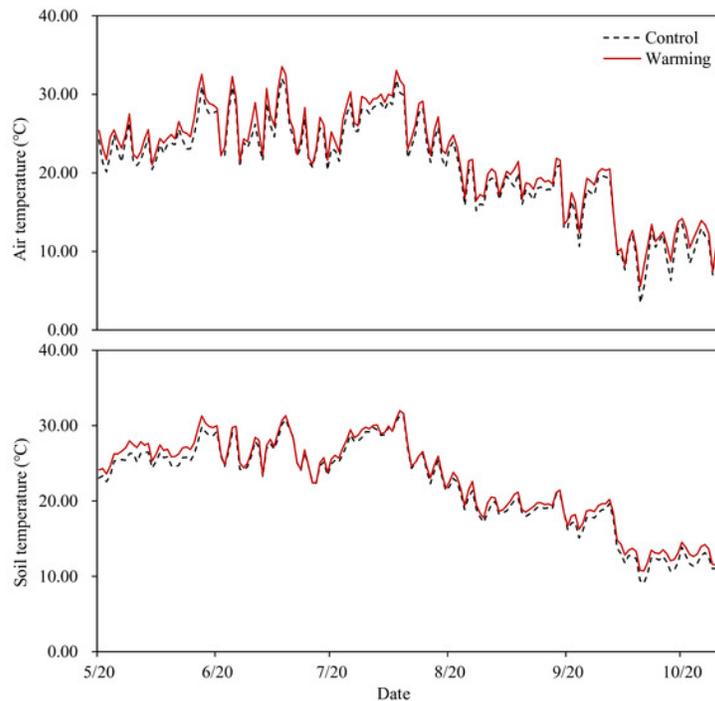

SMC, soil moisture content. SOC, soil organic carbon. TN, soil total nitrogen. TP, soil total phosphorus. DOC, dissolved organic carbon. AN, soil ammonium nitrogen ( $\text{NH}_4^+$ -N) and nitrate nitrogen ( $\text{NO}_3^-$ -N). AP, soil available phosphorus. The results of two-way split-plot ANOVAs for the treatments are shown in the table ( \*  $P < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , and “—” indicate no significance). Lowercase letters show significant differences among the treatments by Duncan’s test at  $p < 0.05$ .

1

# Figure 1

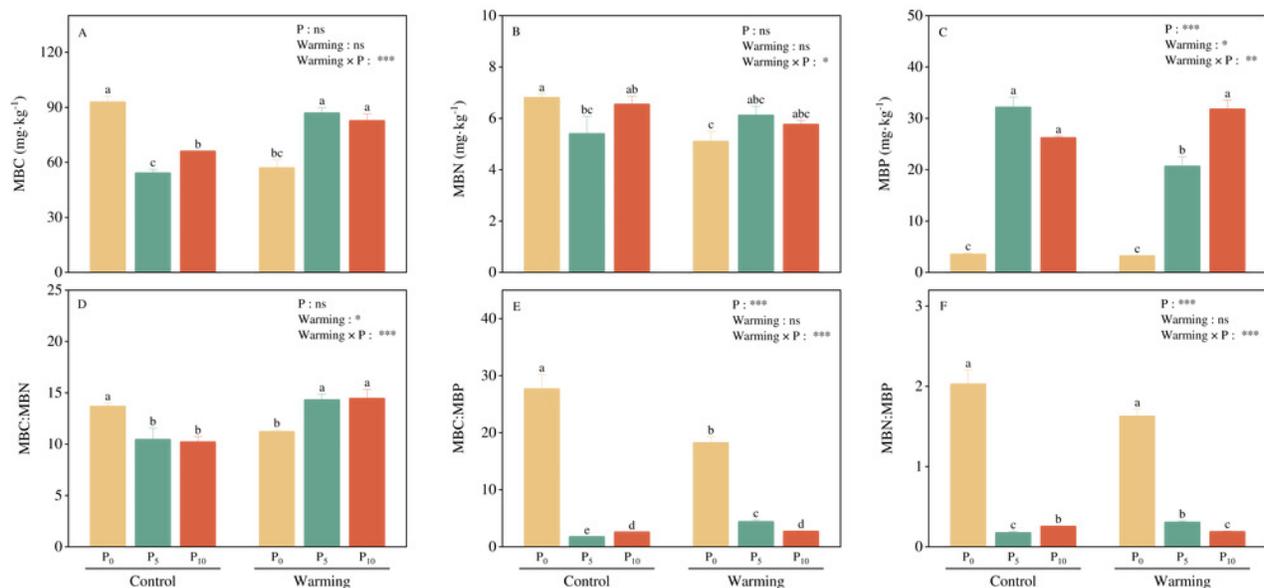

Air temperature at 15cm above the ground and soil temperature at 15cm below the ground in the warming plots (inside of the OTCs) and the control plots (outside of the OTCs).

## Figure 2

Warming, P addition and the interaction effects on soil microbial biomass and stoichiometries.

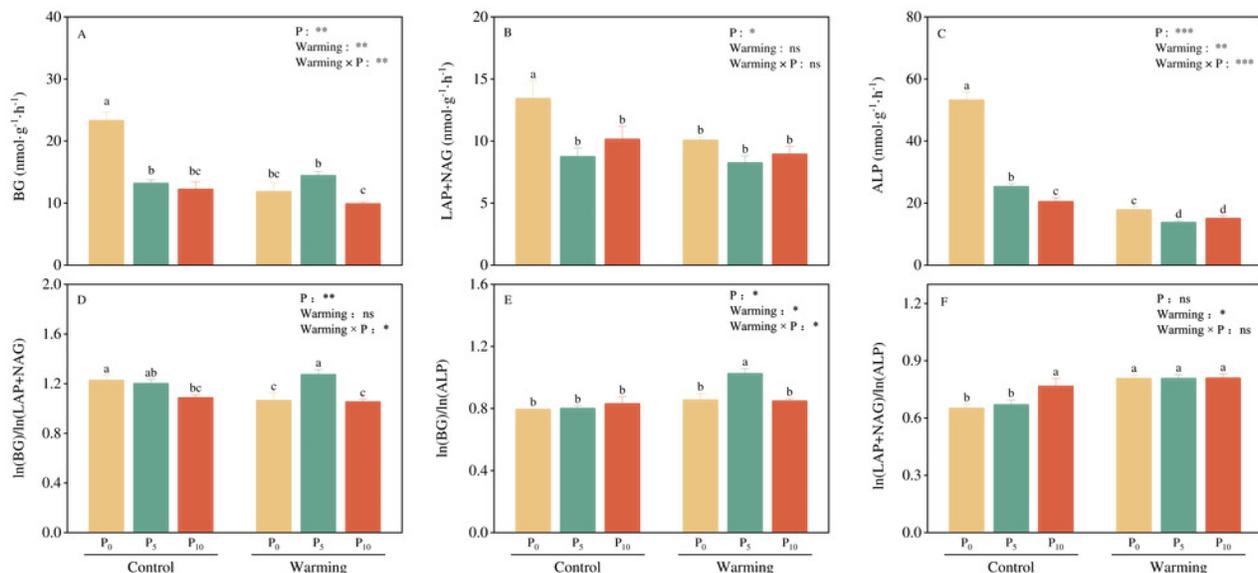

MBC, microbial biomass carbon. MBN, microbial biomass nitrogen. MBP, microbial biomass phosphorus. The results of two-way split-plot ANOVAs for the treatments are shown in the figures (\*  $P < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , and ns indicate no significance), lowercase letters above the multi-factor group histograms show significant differences among the treatments by Duncan's test at  $p < 0.05$ . Error bars show means  $\pm$  SE ( $n=4$ ).

## Figure 3

Warming, P addition and the interaction effects on soil extracellular enzyme activities and stoichiometries.

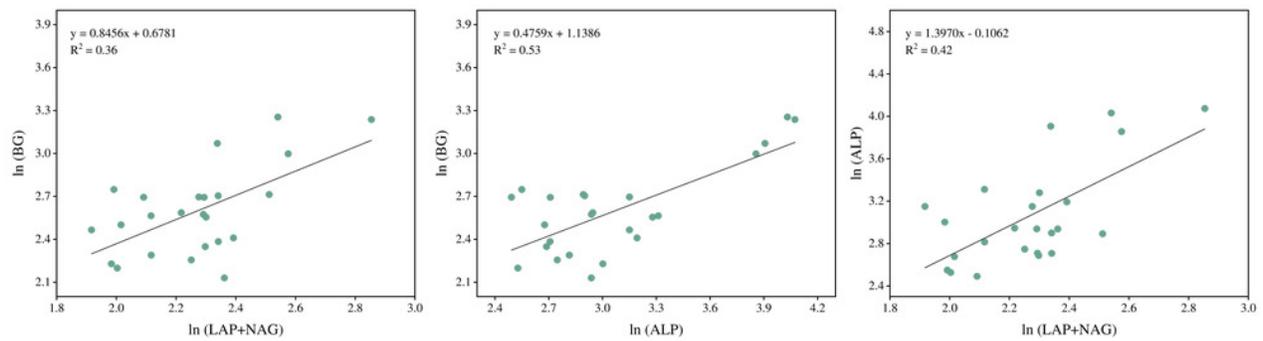

BG,  $\beta$ -1,4-glucosidase. LAP, leucine aminopeptidase. NAG,  $\beta$ -1,4-N-acetylglucosaminidase. ALP, alkaline phosphatase. The results of two-way split-plot ANOVAs for the treatments are shown in the figures (\*  $P < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , and ns indicate no significance), lowercase letters above the multi-factor group histograms show significant differences among the treatments by Duncan's test at  $p < 0.05$ . Error bars show means  $\pm$  SE ( $n=4$ ).

## Figure 4

Regression analysis of the soil C, N, and P acquisition enzyme activities.

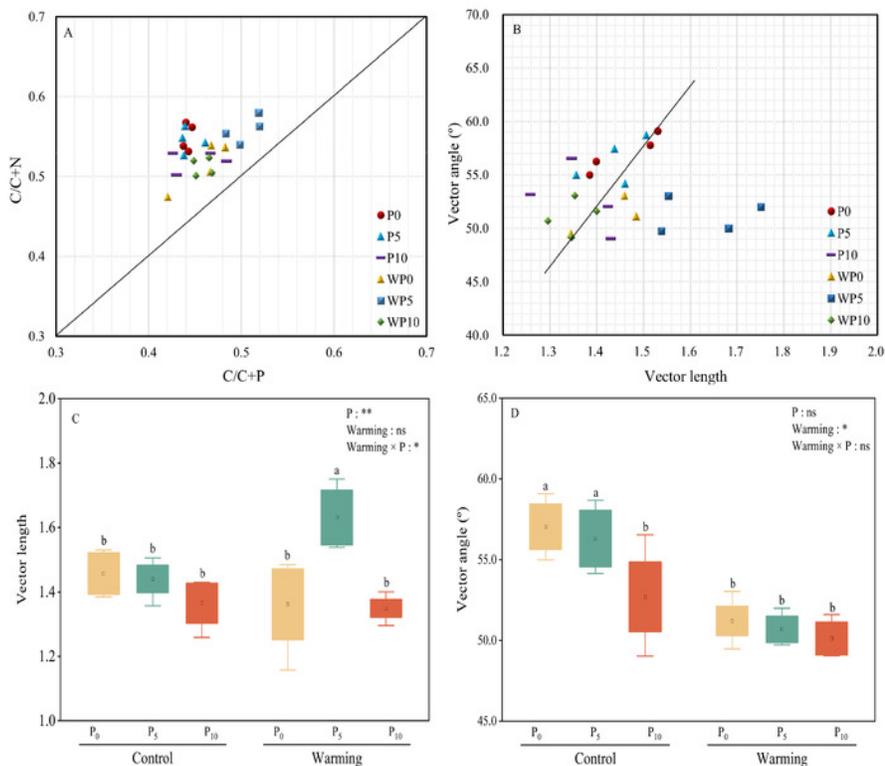

BG,  $\beta$ -1,4-glucosidase. LAP, leucine aminopeptidase. NAG,  $\beta$ -1,4-N-acetylglucosaminidase. ALP: alkaline phosphatase. All data were natural log(ln)-transformed.

## Figure 5

Scatter plots of the eco-enzyme stoichiometry of relative proportions of C/C+P to C/C+N(A). Regression analysis of vector length and vector angle(B). Warming, P addition and the interaction effects on vector length(C) and vector angle(D).

The results of two-way split-plot ANOVAs for the treatments are shown in the figures (\*  $P < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , and ns indicate no significance), lowercase letters above the multi-factor group boxplots show significant differences among the treatments by Duncan's test at  $p < 0.05$ . Error bars show means  $\pm$  SE ( $n=4$ ).

## Figure 6

Correlation analysis on soil properties, soil extracellular enzyme activities and stoichiometries.

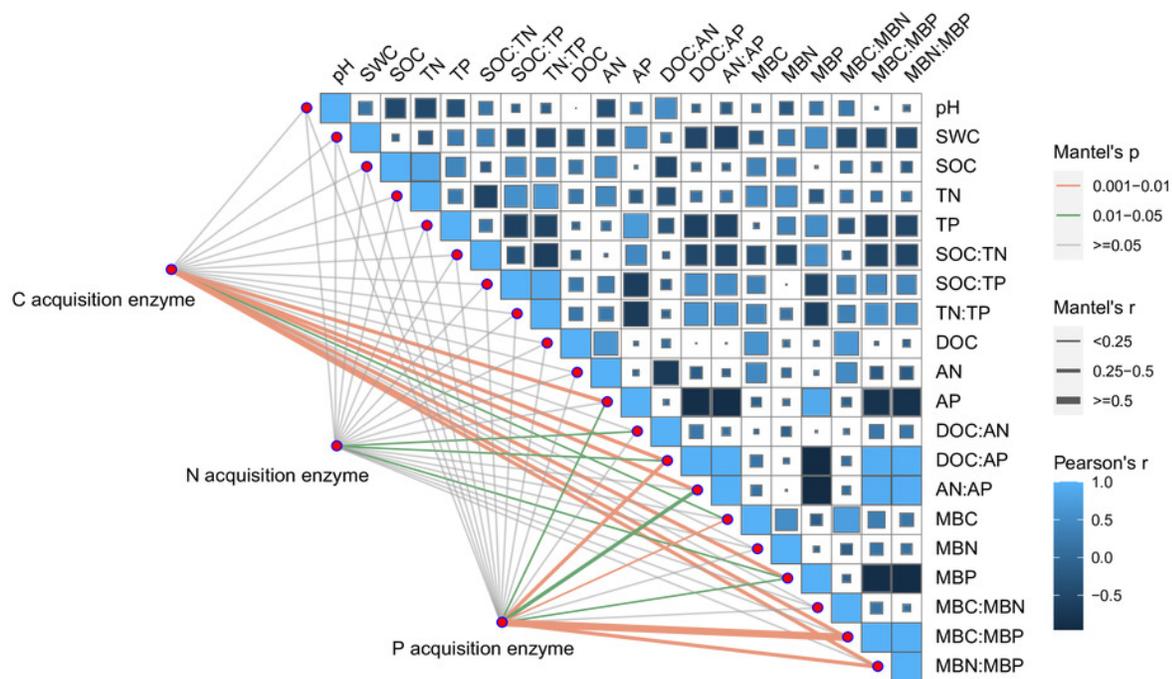

SOC, soil organic carbon. TN, total nitrogen. TP, total phosphorus. SMC, soil moisture content.

DOC, dissolved organic carbon. AN, soil ammonium nitrogen ( $\text{NH}_4^+\text{-N}$ ) and nitrate nitrogen

( $\text{NO}_3^-\text{-N}$ ). AP, soil available phosphorus. MBC, microbial biomass carbon. MBN, microbial biomass nitrogen. MBP, microbial biomass phosphorus. C acquisition enzyme,  $\beta$ -1,4-

glucosidase. N acquisition enzyme, leucine aminopeptidase and  $\beta$ -1,4-N-

acetylglucosaminidase. P acquisition enzyme, alkaline phosphatase.

## Figure 7

Redundancy analysis (RDA) on soil properties, soil extracellular enzyme activities and stoichiometries, vector length, and vector angle.

SMC, soil moisture content. DOC, dissolved organic carbon. AN, soil ammonium nitrogen ( $\text{NH}_4^+\text{-N}$ ) and nitrate nitrogen ( $\text{NO}_3^-\text{-N}$ ). AP, soil available phosphorus. MBC, microbial biomass carbon. MBN, microbial biomass nitrogen. MBP, microbial biomass phosphorus. BG,  $\beta$ -1,4-glucosidase. LAP, leucine aminopeptidase. NAG,  $\beta$ -1,4-N-acetylglucosaminidase. ALP, alkaline phosphatase. e C: N, e C: P, and e N: P represent  $\ln(\text{BG}) : \ln(\text{LAP} + \text{NAG})$ ,  $\ln(\text{BG}) : \ln(\text{ALP})$  and  $\ln(\text{LAP} + \text{NAG}) : \ln(\text{ALP})$ , respectively. VL, vector length. VA, vector angle.
