Background. *Saccharum spp.* is the major source of sugar and plays significant roles in global renewable bioenergy. Sugarcane bacilliform virus (SCBV) is one of the most important viruses infecting sugarcane, causing severe yield losses and quality degradation. It is of great significance to reveal the pathogenesis of SCBV and resistance breeding. However, little is known about the viral virulence factors or RNA silencing suppressors and the molecular mechanism of pathogenesis.

Methods. To systematically investigate the functions of the unknown protein P2 encoded by SCBV ORF2. Phylogenetic analysis was implemented to infer the evolutionary relationship between the P2 of SCBV and other badnaviruses. The precise subcellular localization of P2 was verified in the transient infiltrated *Nicotiana benthamiana* epidermal mesophyll cells and protoplasts by using the Laser scanning confocal microscope (LSCM). The post-transcriptional gene silencing (PTGS) and transcriptional gene silencing (TGS) RNA silencing suppressor activity of P2 was analysed, respectively. And the probable mechanism of P2 on repressing DNA methylation was verified by restriction digestion and RT-qPCR. To explore the pathogenicity of P2, a potato virus X-based viral vector was used to heterologously express SCBV P2, and the consequent H₂O₂ accumulation was detected by 3,3'-diaminobenzidine (DAB) staining method.

Results. Phylogenetic analysis shows that SCBV has no obvious sequence similarity and low genetic relatedness to *Badnavirus* and *Tungrovirus* representatives. LSCM studies show that P2 is localized in both the cytoplasm and nucleus. Moreover, P2 is shown to be a suppressor of PTGS and transcriptional gene silencing TGS, which can not only repress ssRNA-induced gene silencing but also disrupt the host RNA-directed DNA methylation (RdDM) pathway. In addition, P2 can trigger an oxidative burst and cause typical hypersensitive-like response (HLR) necrosis in systemic leaves of *N. benthamiana* when expressed by PVX. Overall, our results laid a foundation for deciphering the molecular mechanism of SCBV pathogenesis and made progress for resistance breeding.

Abstract

Background. *Saccharum spp.* is the major source of sugar and plays significant roles in global renewable bioenergy. Sugarcane bacilliform virus (SCBV) is one of the most important viruses infecting sugarcane, causing severe yield losses and quality degradation. It is of great significance to reveal the pathogenesis of SCBV and resistance breeding. However, little is known about the viral virulence factors or RNA silencing suppressors and the molecular mechanism of pathogenesis.

Methods. To systematically investigate the functions of the unknown protein P2 encoded by SCBV ORF2. Phylogenetic analysis was implemented to infer the evolutionary relationship between the P2 of SCBV and other badnaviruses. The precise subcellular localization of P2 was verified in the transient infiltrated *Nicotiana benthamiana* epidermal mesophyll cells and protoplasts by using the Laser scanning confocal microscope (LSCM). The post-transcriptional gene silencing (PTGS) and transcriptional gene silencing (TGS) RNA silencing suppressor activity of P2 was analysed, respectively. And the probable mechanism of P2 on repressing DNA methylation was verified by restriction digestion and RT-qPCR. To explore the pathogenicity of P2, a potato virus X-based viral vector was used to heterologously express SCBV P2, and the consequent H₂O₂ accumulation was detected by 3,3'-diaminobenzidine (DAB) staining method.

Results. Phylogenetic analysis shows that SCBV has no obvious sequence similarity and low genetic relatedness to *Badnavirus* and *Tungrovirus* representatives. LSCM studies show that P2 is localized in both the cytoplasm and nucleus. Moreover, P2 is shown to be a suppressor of PTGS and transcriptional gene silencing TGS, which can not only repress ssRNA-induced gene silencing but also disrupt the host RNA-directed DNA methylation (RdDM) pathway. In addition, P2 can

trigger an oxidative burst and cause typical hypersensitive-like response (HLR) necrosis in systemic leaves of *N. benthamiana* when expressed by PVX. Overall, our results laid a foundation for deciphering the molecular mechanism of SCBV pathogenesis and made progress for resistance breeding.

Keywords: Sugarcane bacilliform virus, phylogenetic relationship, pathogenic factor, RNA silencing suppressor, hypersensitive-like response.

Introduction

Saccharum spp. is a primary sugar-producing crop and an important industrial renewable bioenergy crop, which is cultivated throughout the world's tropical and subtropical areas. Sugarcane bacilliform virus (SCBV) is one of the primary viruses infecting sugarcane and causing severe damage. It was first identified in cultivar B34104 in Cuba in 1985 (Geijskes et al., 2002), and later purified from cultivar Mex.57-473 (Lockhart, 1988). SCBV is spontaneously spread by the insect vectors *Dysmicoccus boninsis* and *Saccharicoccus sacchari*. It can also be transmitted experimentally by raw viral sap or by Agrobacterium-mediated inoculation (Lockhart et al., 1995), but failed to be transmitted by mechanical friction. In addition, long-distance spread of virus-infected materials is an important means of transmission. SCBV has a relatively broad host range, including *Sorghum halepense*, *Brachiaria* sp., *Rottboellia exaltata*, *Panicum maximum*, and experimental hosts such as *Oryza sativa* and *Musa* sp. (Bouhida et al., 1993; Lockhart et al., 1995; Viswanathan et al., 1996). Usually, the visible symptoms caused by SCBV are mottling, stunted growth, chlorotic streaks, and internode fracture (Viswanathan et al., 1996). Once infection, the sugarcane plants show varying degrees of reduced juice yield, sugar content, gravity purity and stem weight, resulting in significant yield and quality losses (Ahmad et al., 2019). Occasionally, masked symptoms occur due to temperature, drought, nutritional conditions changes. Moreover, much more complicated symptoms could be found due to co-infection with other viruses (Lockhart et al., 1995; Singh et al., 2009; Viswanathan and Premachandran, 1998).

SCBV belongs to the genus *Badnavirus* (family *Caulimoviridae*), with bacilliform, non-enveloped virions of 130-150 nm in length and 30 nm in diameter (Bhat et al., 2016; Bouhida et al., 1993; Lockhart, 1988), containing a circular, covalent, discontinuous dsDNA genome of approximately 7.5-8.0 kilobases (Kb), which generally encodes three open reading frames (ORFs). The exact roles of ORF1 and ORF2 have not been confirmed, and ORF3 has been found to encode a large polyprotein truncated into movement protein (MP), coat protein (CP), aspartic protease (AP), reverse transcriptase (RT) and ribonuclease H (RNase H), but the precise cutting sites remain unknown (Geijskes et al., 2002; Sun et al., 2016). Previous studies have suggested that a short fragment between the 3'-end of ORF3 and ORF1 may act as a strong promoter in both monocot and dicot species (Davies et al., 2014; Gao et al., 2017). The P2 protein of Commelina yellow mottle virus (CoYMV) has been shown to be involved in virion particle assembly (Cheng et al., 1996), and the P2 protein encoded by Cacao swollen shoot virus (CSSV) can bind to cognate or heterologous DNA as well as ssRNA, and the C-terminus appears to be essential for nucleic acid binding (Jacquot et al., 1996). Jacquot and colleagues have demonstrated that the proline-rich region (99-PPKKGKIRKYP_{A-110}) at the C-terminal of Rice tungro bacilliform virus (RTBV) P2

plays an important role in the interaction between P2 and nucleic acids (Jacquot et al., 1997). All these results provide the basis for studying the function of the P2 protein of *Badnavirus*, but little is known about its roles in viral pathogenicity.

In this study, the complete genome of SCBV was deciphered and the functions of its encoded P2 protein were analyzed. The P2 protein was found to share low sequence similarity with other badnaviruses and elicit a hypersensitive-like response and suppress posttranscriptional and transcriptional gene silencing, suggesting that P2 is a viral pathogenicity factor. Our findings increase our understanding of the pathogenesis of SCBV virus and lay a foundation for antiviral resistance breeding.

Materials & Methods

Source of plant materials. Sugarcane plants of the Badila cultivar that exhibited mottling, stunting, and chlorotic streaking symptoms were collected from Menghai County, Yunnan Province, China, and rapidly frozen in liquid nitrogen and then stored at -80 °C.

Multiple alignment and phylogenetic analyses. Amino acid sequence similarities were determined for the P2 of 6 representative members of the genus *Badnavirus* and the sole member of *Tungrovirus* (Rice tungro bacilliform virus, RTBV), all sequences and GenBank accession numbers are listed in Table 1. Sequence multiple alignment was performed with the MegAlign program using the DNASTAR software. The corresponding sequences of the above viruses were aligned, and percent identities were determined in Clustal W. The phylogenetic tree was inferred via the Neighbor-joining method in MEGA11 with the bootstrap 1, 000 replicates.

Construction of plasmids. Total genomic DNA was extracted using cetyltrimethylammonium bromide (CTAB)-based methods as previously described (Springer, 2010). Genomic DNA was purified after RNase A digestion and used as a template for PCR. The complete genome of SCBV was obtained by isothermal amplification with Phi29 MAX DNA Polymerase (Cat#: N106-01, Vazyme, Nanjing, China) according to the manufacturer's instructions. The products of isothermal amplification were then used as templates for amplification of the complete genome using primer pair SCBV/F and SCBV/*Sma*I/R (Table S1) and Phanta EVO HS Super-Fidelity DNA Polymerase (Cat#: P504-d1, Vazyme, Nanjing, China). The SCBV complete genome sequence was then subcloned into the pCE2-TA/Blunt-Zero vector (Cat#: C601-01, Vazyme, Nanjing, China) and transformed into *Escherichia coli* Top10. The positive colonies were cultured and verified by PCR and Sanger sequencing. The complete genome of SCBV was then submitted to National Center for Biotechnology Information (GenBank accession number: OR672147). The ORF2 coding sequence was amplified by PCR and cloned into PVX-based vector pGR106 by digested with *Cla*I and *Sal*I followed by T4 DNA ligase (Cat#: EL0014, ThermoFisher Scientific, Shanghai, China) ligation to get the recombinant plasmid PVX-P2. Also, P2 was inserted to the pCHF3 binary expression vector or fused to the N-terminal of enhanced green fluorescent protein (eGFP) in pCHF3-eGFP by double enzyme digestion with *Sac*I/*Bam*HI. The corresponding recombinant plasmids were referred to as pCHF3-P2 and pCHF3-P2-eGFP, respectively. All primers used in this study are listed in Supplementary Table S1.

Plant growth and agroinoculation. Wild-type, 16c (Voinnet and Baulcombe, 1997), 16-TGS (Raja et al., 2008) and RFP-H2B transgenic seedlings of *N. benthamiana* were grown to the 4- to 5-leaf stage in an insect-free chamber at a constant temperature of 25 °C and a 16-h/8-h day/night cycle. The binary plasmids pCHF3-P2 and empty pCHF3 were transfected into *Agrobacterium tumefaciens* strain EHA105, and the recombinant plasmids PVX and PVX-P2 were transformed into *A. tumefaciens* GV3101 by electroporation. Suspensions of *A. tumefaciens* cultures were regulated to OD₆₀₀ of 1.0, and the *Agrobacterium* containing PVX-P2 was infiltrated into *N. benthamiana* wild-type or 16-TGS seedlings using a 1-mL syringe without a needle. Transient PTGS suppression experiments were conducted as previously described (Johansen and Carrington, 2001; Li et al., 2014; Li et al., 2015).

Plant transformation. The transgenic *N. benthamiana* plants over-expressing P2 or empty vector were generated by using the *Agrobacterium*-mediated leaf disc transformation method. The binary empty vector pCHF3 or recombinant plasmid pCHF3-P2 were transformed into *A. tumefaciens* strain EHA105, and used for transfection of *N. benthamiana* leaf discs. Potential transformants were selected on MS media containing 200 µg ml⁻¹ cefotaxime and 200 µg ml⁻¹ kanamycin. Kanamycin-resistant cluster buds were cut off, placed on rooting media, cultured to a height of 5-6 cm, and then transplanted into soil. Transgenic seedlings were verified by PCR with CaMV 35S promoter or P2 specific primers, respectively. Relative levels of P2 mRNA in transgenic plants were confirmed by RT-qPCR.

H₂O₂ detection in plants. H₂O₂ production was detected visually in *N. benthamiana* leaves using the 3,3'-diaminobenzidine (DAB) staining method (Cat#: A690009, Sangon Biotech, Shanghai, China) (Sharma and Ikegami, 2010) and making some modifications as previously described (Liang et al., 2023).

Subcellular localization analysis. For subcellular localization experiments, fluorescence in RFP-H2B transgenic *N. benthamiana* leaf epidermal cells or protoplasts inoculated with pCHF3-eGFP- and pCHF3-P2-eGFP was examined by confocal microscopy (Leica TCS SP8MP, Mannheim, Germany) 2- to 3-days post inoculation (dpi) as described (Shen et al., 2011; Yoo et al., 2007).

Protoplast preparation. To further observe the more precise subcellular localization of SCBV P2 protein, the protoplasts of RFP-H2B transgenic *N. benthamiana* leaf epidermal cells were prepared by digesting with 1.5% (wt/vol) cellulase (Cat#: A002610, Sangon Biotech, Shanghai, China) and 0.4% (wt/vol) macerozyme R10 (Cat#: A004297, Sangon Biotech, Shanghai, China) as described (Yoo et al., 2007).

DNA methylation analysis by restriction digestion. Genomic DNA of pCHF3 and P2 transgenic plants was extracted by using the CTAB method. Digestion analysis of genomic DNA was performed by using a methylation-insensitive restriction endonuclease *Bam*HI (Cat#: FD0054, ThermoFisher Scientific, Shanghai, China) and a methylation-dependent endonuclease *Mcr*BC (Cat#: M0272, New England Biolabs, Ipswich, MA, USA). The restriction digestion reaction (50 µl) consists of 10 µg of genomic DNA, 50 U of the respective endonuclease according to the manufacturer's specifications. Digested products were instantly separated by electrophoresis through a 1.5% agarose gel.

RT-qPCR. RT-qPCR analysis was performed to measure the transcription level of core genes in the RNA-directed DNA methylation (RdDM) pathway. Total RNAs from PVX-inoculated *N. benthamiana* and P2 or empty vector-transgenic *N. benthamiana* plants were extracted as experimental and control groups using RNAiso Plus reagent (Cat#: 9108, Takara, Beijing, China) and the A_{260}/A_{280} value and concentration of RNA products were measured by NanoPhotometer® N60/N50 (IMPLEN, Germany). 2 µg of high-quality RNA were converted to cDNA using HiScript III 1st Strand cDNA Synthesis Kit (+gDNA wiper) (Cat#: R312-01, Vazyme, Nanjing, China) according to the manufacturer's instructions. The cDNA product was diluted 10-fold and served as a template for RT-qPCR. Each reaction mixture contained 2 µL of the diluted cDNA, 10 µL of 2 × ChamQ Universal SYBR qPCR Master Mix (Cat#: Q711-02, Vazyme, Nanjing, China), 0.4 µL of each of the forward and reverse primer (10 µM) in a total volume of 20 µL (primers are listed in Table S1). Three independent biological and experimental replicates were performed and the reactions were run under the following program conditions: 95 °C for 30 sec, and 40 cycles of 95 °C for 10 sec and 60 °C for 30 sec. Melting curves were derived (95 °C for 15 sec, 60 °C for 60 sec and 95 °C for 15 sec) for each reaction to ensure a single product. Reactions were performed using the LightCycler 96 real-time PCR system (F. Hoffmann-La Roche Ltd. Switzerland). The qPCR data was analyzed by using the $2^{-\Delta\Delta C_t}$ method (Livak and Schmittgen, 2001). All primers used for qRT-PCR detection in this study are listed in Supplementary Table S1.

Immunoblotting. Total protein of systemic leaves was extracted from PVX-infected plants as described previously (Xiong et al., 2009). Immunoblotting was performed with primary Mouse anti-PVX CP monoclonal antibodies, followed by HRP-conjugated Goat Anti-Mouse IgG (Cat#: D110087, Sangon Biotech, Shanghai, China). Blotted membranes were washed thoroughly and visualized using the SuperPico ECL Chemiluminescence Kit according to the manufacturer's protocol (Cat#: E422, Vazyme, Nanjing, China).

Results

Phylogenetic relationships between SCBV P2 and other taxa of the genus Badnavirus

The complete genome of SCBV was sequenced and submitted to NCBI (GenBank accession number: OR672147). The ORF2 of SCBV is 372 nucleotides (nt) long and encodes a small protein of 123 amino acids (aa) called P2. The complete amino acid sequences of SCBV P2, Rice tungro bacilliform virus (RTBV, GenBank accession number: AAD30189), and several representative members of the genus *Badnavirus* (as seen in Table 1) were aligned and phylogenetic analyzed. Multiple sequence alignment shows that all P2 amino acid sequences have no obvious sequence similarity (Fig. 1A, Table 1). A coiled-coil-like domain (47-LLTLHGKITALLEGRLQDLKEDIKKADK₋₇₄) was predicted in SCBV P2 by InterPro online prediction (<https://www.ebi.ac.uk/interpro/>). The coiled-coil like domain is quite conservative in length and position in all the above viruses (Fig. 1A). Phylogenetic analysis shows that all the 8 viruses were clustered into three groups, and SCBV P2 was assigned in a clade alone and had a relatively closer relationship with Banana streak OL virus and Cycad leaf necrosis virus P2, and these three viruses were clustered in the same group (Fig. 1B). We have previously demonstrated

that SCBV P2 can bind to both homologous and heterologous nucleic acids in a sequence-nonspecific manner, and the coiled-coil-like domain plays a major role in P2-nucleic acids binding through self-interaction (Lou et al., 2023), and this is consistent with that of CSSV and RTBV (Jacquot et al., 1996; Jacquot et al., 1997). The above results suggest that although the badnaviruses P2 share little sequence similarity, they all possess a conserved coiled-coil-like domain and play an indispensable role in P2-nucleic acids affinity binding, and this property is conserved in badnaviruses and tungroviruses.

Subcellular localization of the SCBV P2 protein

To determine the precise subcellular localization of SCBV P2, an enhanced green fluorescent protein (eGFP) was fused to the C terminus of P2 (P2-eGFP) and subcloned into the binary expression vector pCHF3 under the transcription of the Cauliflower mosaic virus 35S promoter. *A. tumefaciens* containing the recombinant plasmid pCHF3-P2-eGFP or the pCHF3-eGFP vector were infiltrated into 4- to 5-leaf stage RFP-H2B transgenic *N. benthamiana* plants (containing an RFP nucleus localization signal), respectively. Green fluorescence in inoculum leaves was observed at 2- to 3-dpi using a confocal microscopy. Fluorescence in plants expressing eGFP alone (35S-eGFP) was observed in both cytoplasm and nucleus, and fluorescence in P2-eGFP-infiltrated leaves was also localized in cytoplasm as well as nucleus (Fig. 2A). To further confirm the subcellular localization of P2, the inoculated leaves were digested with cellulase and macerozyme to obtain the protoplasts. The eGFP signal of 35S-eGFP infiltrated mesophyll protoplasts was distributed around the periphery of cytomembrane and nucleus, and it's similar in the 35S-P2-eGFP infiltrated mesophyll protoplasts except some dense bright fluorescent spot (Fig. 2B) The above results indicate P2 have a cytoplasm and nucleus subcellular co-localization.

RNA silencing suppressor activity of SCBV P2

RNA silencing is an efficient innate antiviral mechanism possessed by plants (Li and Wang, 2019). To repress the transcription of viral DNAs, host Dicer-like protein directs TGS through RdDM, or PTGS, which includes splicing and degradation, or translational repression of recognized viral RNA (Boualem et al., 2016; Matzke and Mosher, 2014). To date, the badnaviruses encoded RNA silencing suppressor (RSS) has been rarely reported. As we described previously that SCBV P2 can bind both DNA and RNA (Lou et al., 2023) and is localized in both the cytoplasm and nucleus, suggesting the possibility that it could function as a viral RSS and support viral infection. To test this hypothesis, we used a 16c-transgenic *N. benthamiana* line as the experimental plant, which can constitutively express a green fluorescent protein (GFP) signal localized in the endoplasmic reticulum (ER). *A. tumefaciens* harboring pCHF3-P2 or pCHF3 (negative control) and the p19 suppressor encoded by tomato bushy stunt virus (TBSV) (positive control) was individually mixed with an equal volume of *A. tumefaciens* containing a recombinant plasmid expressing the RNA silencing inducer 35S-GFP and inoculated into 4- to 5-leaf aged 16c-transgenic *N. benthamiana* seedlings. By 4 dpi, the strength of green fluorescence in leaves infiltrated with the pCHF3 empty vector had decreased dramatically under UV light, and was almost undetectable under stereo fluorescence microscope, but the intensity remained relatively high in patches expressing P2, and those inoculated with p19 had the highest fluorescence intensity (Fig. 3A), these data indicate that

SCBV P2 is an RSS, which can suppress single stranded RNA (ssRNA) triggered local gene silencing.

To test whether SCBV P2 can suppress dsRNA-induced gene silencing, wild-type *N. benthamiana* plants of 4- to 5-leaf age were infiltrated with *A. tumefaciens* solutions containing the same volume of transient dsRNA elicitor 35S-GFP and 35S-dsFP together with pCHF3, pCHF3-P2, and pCHF3-p19, respectively. As shown in Fig. 3B, leaf spots infiltrated with neither pCHF3 nor pCHF3-P2 mixed with the silencing inducer did not show any GFP fluorescence at 4 dpi under UV light or stereo fluorescence microscopy, indicating that P2 fails to suppress dsRNA-induced RNA silencing. In contrast, high intensity of green fluorescence was observed in patches expressing the p19 positive control (Fig. 3B). The above data suggest that SCBV P2 is a weak local ss-PTGS but not a ds-PTGS suppressor.

To determine whether P2 can also conquer TGS, a transgenic *N. benthamiana* line named 16-TGS (the CaMV 35S promoter of the GFP transgene is transcriptionally silenced) was used. Transgenic seedlings of 4- to 5-leaf stage were inoculated with GV3101 *A. tumefaciens* solutions (mock) or PVX-P2, PVX (negative control), or PVX- β C1 (the TGS repressor of tomato yellow leaf curl China betasatellite (TYLCCNB), positive control), respectively. After 21 dpi, PVX-infected plants were almost asymptomatic and no visible green fluorescence was detected in systemic tissues under a high intensity UV lamp. However, PVX- β C1-infected plants exhibited severe dwarfing, stem deformation and upward leaf curling along with the PVX-immanent mosaic symptoms, and GFP fluorescence was quite noticeable. As shown in Fig. 3C, systemic leaves infected with PVX-P2 showed severe mosaic and spotty mottling symptoms accompanied with visible green fluorescence under UV light (Fig. 3C), indicating that P2 is a potential TGS repressor.

SCBV P2 expression impacts RdDM signaling in the host

In plants, DNA methylation is a conserved epigenetic modification that regulates genome stability, gene expression, and antiviral defense (He et al., 2022; Wang et al., 2019; Zhang et al., 2018). And the methylation level of the plant host is reprogrammed when challenged by an invading virus. To investigate the effect of P2 on the global methylation patterns of the host plant, we constructed a transgenic P2 line of *N. benthamiana* and tested methylation at the genome level using a methylcytosine-dependent endonuclease (*Mcr*BC). Genomic DNA from pCHF3 (Vec) and P2 transgenic *N. benthamiana* plants (5# and 9#) were extracted and subsequently processed with restriction digestion assays. A mock treatment without enzyme was performed as a control (Sham), and all genomic DNA samples remained unaltered. When a methylation-insensitive endonuclease (*Bam*HI) was used, we found that all three genomic DNA samples were digested and formed a ‘smear’ pattern on the agarose gel during electrophoresis (Fig. 4A). However, *Mcr*BC treatment cleaved a portion of the Vec DNA, whereas the DNA from the P2 transgenic lines showed high resistance and remained unchanged (Fig. 4A). The present data suggest that P2 can reduce DNA methylation on a genome-wide scale when transgenically expressed in *N. benthamiana* plants.

To explore the possible mechanism of SCBV P2 in repressing epigenetic TGS and genome-wide DNA methylation, the relative expression levels of the homologous genes of DNA methyltransferases, demethylases, histone deacetylase and essential genes related to the RdDM

pathway were analyzed in P2 or empty vector transgenic *N. benthamiana* plants. Specific primers were designed and synthesized for qRT-PCR detection of the homologs of DNA methyltransferases (MET1, DRM2 and CMT3), demethylases (ROS1, ROS2), argonautes (AGO1-1, AGO4-1), dicers (DCL3), and histone deacetylase 6 (HDA6). Total RNA from empty vector (Vec) and P2 transgenic *N. benthamiana* plants was extracted 4 weeks after sowing, and total RNA from PVX- or PVX-P2-infected *N. benthamiana* plants was isolated at 15 dpi. The above RNA was reverse transcribed into cDNA and serves as template for the subsequent RT-qPCR assays. As shown in Fig. 4B and 4C, the expression of *NbAGO1* was significantly down-regulated in both P2 transgenic plants and PVX-P2-infiltrated plants, and the expression of *NbAGO4* was dramatically reduced in P2 transgenic *N. benthamiana* plants but remained inconspicuous in PVX-P2-inoculated plants (Fig. 4B and 4C). Surprisingly, we found that the expression level of *NbHDA6* was also significantly down-regulated in both P2 transgenic plants and PVX-P2-infiltrated plants, and HDA6 was proved to be a histone deacetylase and cofactor of MET1 that promotes DNA methylation. Taken together, our findings show that P2 consistently overexpression decreases *NbAGO1* and *NbHDA6* expression so as to suppress host TGS.

SCBV P2 induces a hypersensitive-like response (HLR) in *N. benthamiana*.

SCBV infection usually causes pathchy, chlorotic streaking symptoms (Viswanathan et al., 1996), and induces broken chlorotic streaks in inoculated rice (Bouhida et al., 1993). We successfully constructed an infectious clone of SCBV by inserting a 1.06 copy of the tandem viral genome into the binary vector pCB301-2×35S-HDVRZ-NOS (Fig. S1, A and B). After *Agrobacterium*-mediated inoculation, SCBV-infected rice seedlings showed stunting and broken chlorotic streaks on leaves at 21 dpi (Fig. S1, C), consistent with the results of Bouhida and colleagues (Bouhida et al., 1993). We also investigated whether the necrotic streaks were the results of a hypersensitive-like response. The rice leaves that showed typical necrotic streaks were stained with 3,3'-diaminobenzidine (DAB), and the mock and pCB301-2×35S-HDVRZ-NOS empty vector infiltrated plants were used as controls. As shown in Fig. S1, brown necrotic spots appeared in leaves infected with SCBV, whereas plants inoculated with mock and empty vector remained transparent and speckless. The accumulation of viral genomic DNA was verified by PCR analysis, and the results indicate that infectious SCBV can successfully infect rice and cause H₂O₂ accumulation-induced HLR.

To evaluate whether SCBV P2 is a symptom elicitor in *N. benthamiana*, the P2 protein was ectopically overexpressed by a PVX-based vector. *N. benthamiana* plants of 4- to 5-leaf stage were inoculated with *A. tumefaciens* harboring PVX or PVX-P2, respectively. At 7 dpi, PVX-infected plants began to show typical mosaic and shriveling symptoms, whereas PVX-P2-infiltrated plants remained symptomless (Fig. 5A, upper panels). At 10 dpi, the symptoms of PVX-P2-infected plants resembled those of PVX-infected plants (Fig. 5A, middle panels). Symptoms of PVX-infected plants showed signs of recovery from 12 dpi, and vein chlorosis and mosaic phenotype disappeared by 20 dpi, whereas P2-expressing plants still exhibited mosaic and leaf wrinkling phenotypes (Fig. 5A, lower panels). These findings suggest that SCBV P2 can delay the onset of host symptoms to some extent and persist for a considerably longer period of time. To demonstrate

the relationship between necrosis and H₂O₂ accumulation, the 3,3'-diaminobenzidine (DAB) staining assay was performed to detect the accumulation of H₂O₂ in empty or PVX-P2 inoculated plants at 10 dpi and 20 dpi, and we found that P2-expressing leaves had many brown necrotic spots at 20 dpi, whereas leaves inoculated with the vector remained spotless (Fig. 5B). Protein immunoblotting analyses confirmed that PVX CP accumulated in greater amounts in PVX-P2-inoculated plants than that in PVX-inoculated plants (Fig. 5C), suggesting that P2 is a potential virulence factor that promotes PVX replication and accumulation. These results indicate that SCBV P2 protein is a viral pathogenicity factor that can induce a hypersensitive-like response and promote virus accumulation.

Discussion

Sugarcane bacilliform virus (SCBV) is an important member of *Badnavirus* that causes severe quality and yield losses worldwide. Although many efforts have been made to reveal the molecular characteristics, pathogenicity, and pathogenesis of SCBV, little is clear. We previously demonstrated that the P2 protein of SCBV can bind both viral and heterogenous DNA or RNA in a sequence nonspecific manner (Lou et al., 2023), which is consistent with the findings of CSSV, CoYMV, and RTBV (Cheng et al., 1996; Jacquot et al., 1996; Jacquot et al., 1997). Although the P2 proteins of badnaviruses do not show obvious sequence homology (Fig. 1), they all possess nucleic acid binding activity, which appears to be a universal property of badnaviruses P2 proteins. Furthermore, we have proved that the coiled-coil-like region in P2 is critical for self-interaction and nucleic acid binding (Lou et al., 2023), and the coiled-coil-like region is fairly conserved in size and position among *Badnavirus* and *Tungrovirus*, indicating its universal crucial role for the P2 protein. Since P2 has the ability to bind nucleic acids, it could play a key role in preserving viral nucleic acids from degradation or be involved in virion assembly.

RNA silencing is an evolutionarily conserved immune barrier in microbes, such as plant viruses (Li and Wang, 2019). To overcome this defense, viruses have evolved a variety of proteins (such as RSSs) capable of suppressing host gene silencing by other PTGS or TGS via the RdDM pathway (Boualem et al., 2016; Matzke and Mosher, 2014). In general, viral-encoded RSSs are multifunctional and can play critical roles in various stages of the virus infection in addition to suppressing RNA silencing (Csorba et al., 2015; Yang and Li, 2018). For example, CaMV P6 has been proved to act as an RSS by suppressing the activity of DRB4 (Haas et al., 2015). RTBV P4 can inhibit the production of siRNA to suppress RNA silencing (Rajeswaran et al., 2014). Here, we tested the PTGS repressor activity of SCBV P2 and found that P2 can inhibit sense RNA-induced but not dsRNA-induced PTGS (Fig. 3), implying that P2 may also repress the formation of dsRNA or degradation but has no effect on siRNA metabolism. In fact, some other Caulimovirus-derived suppressor proteins, such as P6 encoded by strawberry vein banding virus (SVBV), may interfere with dsRNA degradation and act as an RSS (Feng et al., 2018).

RdDM is a common epigenetic modification that plays critical roles in gene expression regulation and defense against invading viruses. As a counter-defense strategy, some plant viruses encode TGS suppressors as a tactic to block the activity of essential enzymes or protect the substrates from degradation in the subsequent methylation cycle (Ismayil et al., 2018; Raja et al.,

2008; Yang et al., 2011; Zhang et al., 2011). For example, HC-Pro protein from the *Potyviridae* family is involved in lots of processes of RNA silencing suppression by blocking methylation of the 3'-end of siRNA or directly binding to AGO1 and downregulating its expression, etc. (Valli et al., 2018). And the P0 proteins from the genus *Polerovirus* have been shown to block the binding of siRNAs/miRNAs to the free AGO effector to form an intact RNA-induced silencing complex (RISC) and mediate the degradation of AGO1 via the autophagy pathway (Csorba et al., 2010; Michaeli et al., 2019). In this study, we verified that SCBV P2 inhibits TGS by suppressing the expression of AGO1 and AGO4 (Fig. 4B and 4C), which were known to defend against plant RNA viruses (Morel et al., 2002; Wu et al., 2015; Zhang et al., 2006) and DNA viruses (Raja et al., 2008), respectively. AGO1 regulates gene expression in a variety of developmental and physiological processes (Fei et al., 2013; Rogers and Chen, 2013). It also functions in virus defense when loaded with viral siRNAs via dsRNA-triggered gene silencing (Fang and Qi, 2016; Wu et al., 2015), and in this study P2 downregulate the expression level of *NbAGO1* but had no visible influence on ds-PTGS (Fig. 3 and 4), although the details remain to be elucidated. The AGO4 protein is a crucial component of the RdDM pathway that recruits DRM2, a major de novo methyltransferase, to add methyl to target DNA (Cao and Jacobsen, 2002; Zhong et al., 2014). Furthermore, we found that SCBV P2 transgenic plants showed much lower levels of methylation genome-wide than empty vector transgenic seedlings (Fig. 4A). Taken together, these results provide a model that SCBV P2 represses host DNA methylation by suppressing or disrupting various components involved in the DNA methylation pathway.

Oxidative burst (including O_2^- and H_2O_2) induced HR (Mubin et al., 2010) is universal when plants respond to pathogens and is thought to limit pathogen growth or movement (Hussain et al., 2007; Lam et al., 2001). In this study, we found that SCBV P2 could induce typical mosaic symptoms and HLR necrosis in the late stage of infection with a PVX-based vector (Fig. 5). This suggests that P2 somewhat delays the onset of viral symptoms but triggers H_2O_2 accumulation and causes necrosis symptoms. These results are consistent with the findings of inoculation with infectious clone in *Oryza sativa* (Fig. S1), further confirming that P2 is the pathogenic factor encoded by SCBV. Intriguingly, several plant DNA viruses encoding TGS suppressors have been verified to be virulence factors inducing HR, such as the V2 protein of papaya leaf curl virus (PaLCuV), cotton leaf curl Kokhran virus (CLCuKoV) and tomato leaf curl Java virus (ToLCJV) (Hussain et al., 2007; Mubin et al., 2010; Sharma and Ikegami, 2010). Based on the above results, we suppose that the pathogenesis and TGS repressor activity of SCBV P2 are coupled. Altogether, these observations indicate that SCBV P2 is a multifunctional protein that can suppress PTGS and TGS as well as induce HLR. All these findings help to elucidate the molecular pathogenesis of *Badnavirus* and provide a possible target for future antiviral breeding.

Conclusions

Our work reveals the fact that the P2 protein encoded by sugarcane bacilliform virus (SCBV) plays an important role in the pathogenicity of the virus, which serves as a ss-PTGS suppressor and represses host TGS by impairing host genome wide DNA methylation level and inhibiting core

genes transcription in RdDM pathway, such as AGO1. Besides, P2 was proved to be a virulence factor, which can induce HLR and assist PVX accumulation in *N. benthamiana*. Our conclusions increase the awareness of the molecular mechanism of pathogenesis, as well as help lay a foundation for disease resistance breeding.

Acknowledgements

We thank professor Xueping Zhou from Institute of Plant Protection, Chinese Academy of Agricultural Sciences for kindly giving the PVX-based expression vector and Mouse anti-PVX CP monoclonal antibody. And we also thank professor Xiaorong Tao from Nanjing Agriculture University for kindly providing the pCB301-2×35S-HDVRZ-NOS binary vector.

Figure 2. Subcellular localization of SCBV P2 in RFP-H2B transgenic *Nicotiana benthamiana* mesophyll cells and protoplasts.

(A) Subcellular localization of P2 fused to the enhanced green fluorescent protein (eGFP) in RFP-H2B transgenic *N. benthamiana* mesophyll cells. (B) Subcellular localization of P2 fused to eGFP in RFP-H2B transgenic *N. benthamiana* protoplasts. The 35S-eGFP expression plasmid was used as a control. The ratio scale was shown in the bottom right corner of the picture.

Figure 3

Figure 3. SCBV P2 inhibits ssRNA induced PTGS and reverses TGS.

(A) Repression of GFP silencing in *N. benthamiana* 16c leaves. Leaf areas were co-infiltrated with *A. tumefaciens* expressing GFP (35S-GFP) and either a pCHF3 control, SCBV P2 (pCHF3-SCBV-P2), or TBSV p19 (pCHF3-p19). Photos of the above infiltrated leaves were taken at 4 dpi, under high intensity UV light. (B) Leaf patches of *N. benthamiana* were co-infiltrated with *A. tumefaciens* carrying GFP (35S-GFP) and dsFP (35S-dsFP), as well as pCHF3 vector, SCBV P2 or p19, and typical leaf patches were photographed under high intensity UV light at 4 dpi. (C) Plant of *N. benthamiana* 16-TGS were left uninoculated, or inoculated with PVX, PVX-P2, or PVX- β C1, respectively, and the apex of plants and leaves were photographed under high intensity UV light at 21 dpi.

Figure 4

Figure 4. SCBV P2 expression impacts host RdDM pathway and genome-wide scale methylation.

(A) DNA methylation analysis in P2 transgenic *N. benthamiana* plants using restriction endonuclease digestion. The methylation-dependent endonuclease *McrBC* and the methylation-insensitive enzyme *BamHI* were used to digest genomic DNA isolated from the vector control (Vec) and two separate lines of P2 transgenic plants (5# and 9#). The term 'Sham' refers to a simulated digestion that contains no enzyme. The positions of the uncut input and the digested products are shown. (B) SCBV P2 Overexpression inhibits transcription of *N. benthamiana* ARGONAUTE 1 (*NbAGO1*) and *NbAGO4* in PVX-treated plants. RT-qPCR assays were performed to analyze the effects of P2 on the expression of homologous genes of DNA methyltransferases, demethylases, histone deacetylase and essential genes related to RdDM. Relative expression levels of DNA METHYLTRANSFERASE1 (*NbMET1*) [GenBank accession number: FJ222441], DOMAINS REARRANGED METHYLTRANSFERASE2 (*NbDRM2*) (JQ957857), CHROMOMETHYLASE3 (*NbCMT3*) (JQ957858), DICER3 (*NbDCL3*) (FM986782), REPRESSOR OF SILENCING 1 (*NbROS1*) (JQ957859), *NbROS2* (JQ957860), *NbAGO1* (DQ321488), *NbAGO4* (DQ321490) and Histone Deacetylase 6 (*NbHDA6*) (KU170188) were measured in PVX and PVX-P2 inoculated *N. benthamiana* plants at 15 dpi (B), or in pCHF3 vector and P2 transgenic plants at 30 days after sprouting [C]. T-tests were performed to analyze the significance of difference (* $P < 0.05$, ** $P < 0.01$). Each of the experiments were carried out at least three times.

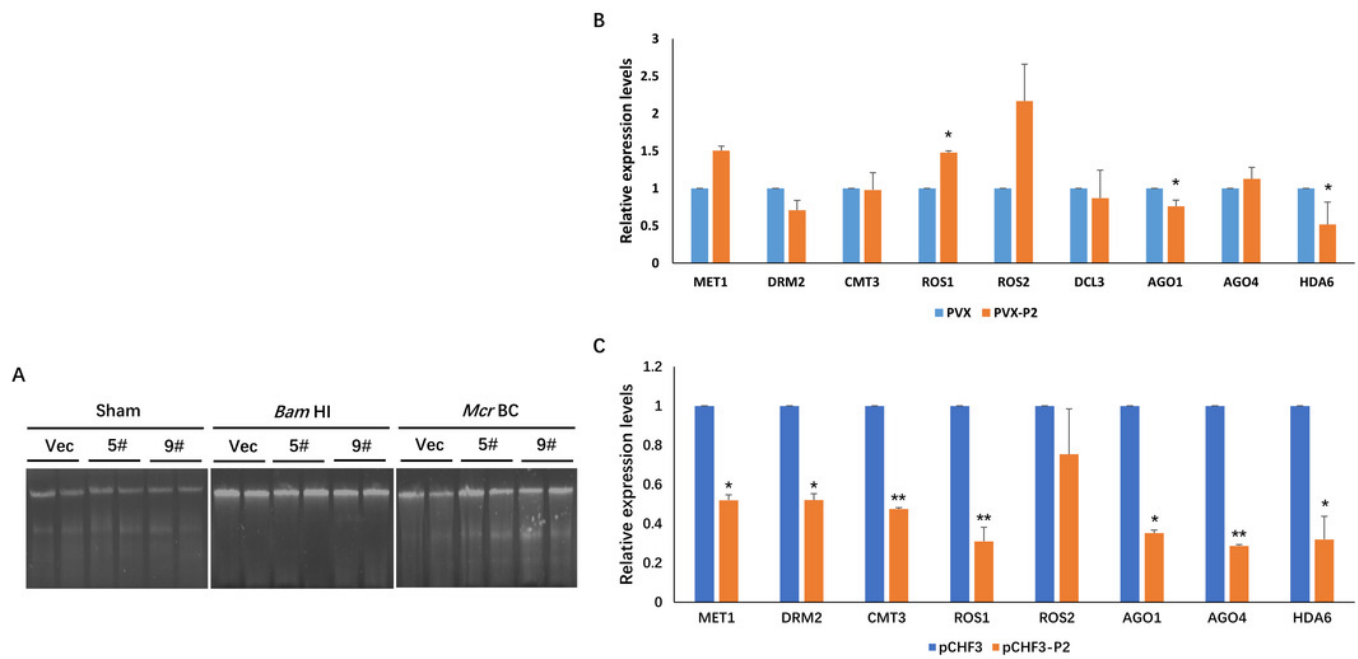

Figure 5

Figure 5. Symptoms of the plants inoculated with Potato virus X(PVX) or PVX-P2.

(A) Symptoms evoked on *N. benthamiana* plants at 7-, 10- and 20-dpi inoculated with PVX or PVX-P2. (B) PVX-P2 induced mosaic symptoms and necrotic spots on *N. benthamiana* plants. Upper systemic leaves were photographed at 10- and 20-dpi, respectively. Followed by photographing after 3,3'-diaminobenzidine (DAB) treatment. The necrotic lesions are shown by the red arrowheads. (C) Western blot analysis of coat protein (CP) accumulation in PVX or PVX-P2 infected plants. Freshly emerging leaves were used to extract total protein. The anti-PVX CP monoclonal antibody was used to detect the accumulation of PVX, Coomassie light blue stained Rubisco large subunit protein was used as a loading control. The gray values of the blot bands were evaluated by using the ImageJ software, the relative amount of CP accumulation in PVX-infected plants was preset as 100%.
