# Abstract

**Background.** Inflammation and metabolic disorder caused by obesity are important factors leading to the occurrence and development of obesity complications. In the present study, we investigated the protective effect and underlying mechanism of a novel pyrimidine-2,4-diamine derivative, cyy-287, in high-fat diet (HFD) mice.

**Methods.** Based on their diets for 10 weeks, the mice were categorized into the following four groups ( $n \geq 7$ ): control (regular diet), HFD, HFD with Cyy-287 (5 mg/kg), HFD with Cyy-287 (20 mg/kg) for 10 weeks. Echocardiography revealed the parameters of diastolic function of the heart. Hematoxylin and eosin (HE) staining of the sections revealed hepatic steatosis.

**Results.** Cyy-287 administration increased ejection fraction (EF) and fractional shortening (FS) index and decreased the the levels of serum glucose and lipid markers and transaminase activities in HFD mice. Furthermore, Cyy-287 inhibited the histopathological changes in the heart and liver and decreased inflammatory activity. Significantly, Cyy-287 diminished p38 mitogen-activated protein kinase (MAPK), the nuclear factor-kappa B (NF- $\kappa$ B) axis and sterol regulatory element-binding protein-1c (SREBP-1c), as well as upregulated the AMP-activated protein kinase (AMPK) pathway, in HFD mice.

**Conclusions.** These findings suggest that that Cyy-287 protected heart and liver cells from obesity-induced damage by inhibiting inflammation, fibrosis and lipid synthesis.

**Keyword:** Cyy-287, inflammation, obesity complications, p38, AMPK

# Introduction

Obesity is a common public health problem that is often accompanied by a variety of complications, such as cardiovascular and cerebrovascular diseases, nephropathy, diabetes, and fatty liver (Caballero, 2019; Polyzos, Kountouras & Mantzoros, 2019; Piche, Tchernof & Despres, 2020). All these complications pose a serious threat to the health of obese patients and reduce their quality of life. Although weight controlling can alleviate its progression, drug treatment is still one of the most efficiency ways to alleviate the development of obesity complications (Jackson *et al.*, 2015; Narayanaswami & Dwoskin, 2017; Srivastava & Apovian, - 2018). At present, the basic treatment strategies include blood pressure reduction, lipid reduction, hypoglycemic, and so on (Tanaka, 2020; Klop & Elte, 2013). However, these treatments cannot block the progression of the disease completely. Therefore, it is necessary to determine new therapeutic strategies and develop new therapeutic drugs.

Chronic inflammation, intracellular mitochondrial dysfunction, insulin resistance, metabolic disorders, autophagy, and endoplasmic reticulum stress are important mechanisms that induce obesity complications (Ye, 2021; Fu *et al.*, 2011; Goldman S, Zhang & Jin S, 2010; Aron-Wisnewsky *et al.*, 2020). Among them, the inflammatory response is a crucial process in the development of tandem pathologym (Cox AJ, West & Cripps., 2015). Nuclear factor- $\kappa$ B (NF- $\kappa$ B) regulates a large number of genes involved in different processes of the immunomodulatory responses. The mechanism of NF- $\kappa$ B activation is the inducible degradation of I $\kappa$ B $\alpha$  triggered through its site-specific phosphorylation by a multi-subunit I $\kappa$ B kinase (IKK) complex. IKK can be activated by various factors, including cytokines, growth factors, mitogens, and stress agents (Nguyen & Stamper, 2017). Recently, it has been suggested that sporoderm-broken spore of *Ganoderma lucidum* (BSGLP) can inhibit the upregulation of the NF- $\kappa$ B signaling pathway in adipose tissue induced by high-fat diet (HFD), thus suppressing obesity and hyperlipidemia by modulating inflammation, gut microbiota, and intestinal tract barrier function (Sang., 2020). Another study has confirmed that controlling adipose inflammation mediated by adipose tissue macrophages can improve metabolic dysfunction and reduce obesity (Wu, Shi & Wang, 2021). Consequently, blocking inflammatory response by targeting NF- $\kappa$ B pathway may be an effective way against obesity complications.

AMP-activated protein kinased (AMPK), a serine/threonine protein kinase, senses cellular energy status and is activated by higher AMP/ATP or ADP/ATP ratios (Lv *et al.*, 2019).

Its functions extend to various pathways, including those linked to metabolic diseases (*Fogarty et al, 2016*). Emerging evidence shows that AMPK activation is beneficial for the treatment of several metabolic diseases, including obesity and nonalcoholic fatty liver disease (NAFLD) (*Garcia et al., 2019*). And several natural compounds and synthetic drugs have been recognized to prevent obesity-related renal injury, cardiomyopathy, and hepatic damage by activating AMPK and its downstream pathways (*Li et al., 2021; Li et al;2022* ). In addition, AMPK activation can effectively prevent inflammation induced hepatic steatosis through the IKK/NF- $\kappa$ B signaling pathway (*Li et al., 2018; Jiang et al., 2021*). Based on these studies, we speculate that targeting AMPK pathway could represent a new potential strategy for obesity complications.

Previously, we investigated the antitumor effect and underlying mechanism of a novel pyrimidine-2,4-diamine derivative, Cyy-287 (**Fig. 1A**), in non-small cell lung cancer (*Zhang et al., 2022*). Due to the fact that C57BL/6J mice exhibited comparable phenotypes to those found in human diabetes and metabolic disorders following a high-fat diet, we developed a mouse model of high-fat diet-induced obesity using C57BL/6J mice. We found that the differential genes between the control group and the cyy-287 group were enriched in the inflammatory pathway. In present study, our data suggested that Cyy-287 could efficiently block the chronic inflammation and de novo lipogenesis in HFD mice, and its mechanism might be related to the MAPK/NF- $\kappa$ B and AMPK/SREBP-1c pathways.

## Materials & Methods

### Chemicals and reagents

Cyy-287 was synthesized as previously described by our laboratory with a purity over 98% (*Zhang et al., 2022*). Antibodies against p38 (#8690), P-p65 (#3033), P-AMPK (#2535), P-p38 (#4511) were purchased from Cell Signaling Technology (Boston, USA). Antibodies against Collagen- I (#14695-1-AP) and tubulin (#11224-1-AP) were purchased from Proteintech (Wuhan, China). Anti-SREBP-1c (#abs152294) was obtained from Absin (Shanghai, China). Antibodies for immunohistochemical staining including anti-F4/80 (#ab300421) and anti-TNF- $\alpha$  (#ab183218) were obtained from Abcam (MA, USA). Secondary antibody (#111-585-003) was acquired from Jackson ImmunoResearch (West Grove, USA) and secondary antibody for immunohistochemical staining (#GB23301; #GB23303) were purchased from Servicebio (Wuhan, China). Alanine aminotransferase (ALT) kit (#C009-2-1) and aspartate

aminotransferase (AST) kit (#C010-2-1) were obtained from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). Hematoxylin (#G1005), Masson (#G1006) and Sirius red (#G1018) dye solution used for staining of tissue sections were purchased from Servicebio (Wuhan, China).

# **Animal models**

All animal care and experimental procedures were approved on 20-May-2019 by the NIH Guide for the Care and Use of Laboratory Animals approved by the Laboratory Animal Ethics Committee of Wenzhou Medical University for which the Approval ID is WYDW-2019-0809. A total of 36 male C57BL/6J mice weighing 18-22 g were purchased from Vital River Laboratory Animal Center and all were housed in an environmental control room at a temperature of  $20 \pm 2$  °C and a humidity of  $50 \pm 5\%$  with a light/dark cycle of 12 h. During the experimental period, mice had unrestricted access to food and water.

Obesity was induced by feeding the mice a high-fat diet (HFD) consisting of 60% fat, 20% protein, and 20% carbohydrate (#D12492) and control mice were fed a standard control diet composed of 10% fat, 20% protein, and 20% carbohydrate. After adaptive feeding for 7 days, the mice were randomly divided into four groups ( $n \geq 7$ ): (1) the control group ( $n = 7$ ); (2) the HFD group ( $n = 9$ ); (3) the Cyy-287 (5 mg/kg) treated HFD group ( $n = 10$ ); (4) the Cyy-287 (20 mg/kg) treated HFD group ( $n = 10$ ), according to the principle of random grouping, each animal has an equal chance to be assigned to each experimental group and the control group. After feeding mice with high-fat diet or standard diet for 10 weeks, Cyy-287 was administered daily by gavage at a dose of 5 mg/kg or 20 mg/kg for 10 weeks, mice in control group were given equal volume of normal saline by oral administration. And the body weight was recorded every week. At the 20<sup>th</sup> week, the blood glucose of mice was recorded with a blood glucose meter. Afterwards, we collected serum samples from mice, followed by collecting liver and heart tissues through gradual CO<sub>2</sub> asphyxiation and cervical dislocation euthanasia.

# **Measurement of biochemical parameters**

A certain weight of liver tissue was weighed, and 9 times of volume of normal saline was added. Under the condition of ice-water bath, mechanical homogenization was performed at 2500 rpm, and centrifugation was performed for 10 min. After the supernatant was further diluted 50 times, ALT and AST enzymes were determined using homologous kits. Taking heparin as anticoagulant, the blood samples were collected and centrifuged at 3,000 rpm at 2-8 °C for 15 min, and the supernatant was taken, and the serum lipids were detected by automatic biochemical

analyzer (Chemray 240).

### **Echocardiography**

The parameters of diastolic function of the heart, such as ejection fraction (EF%) and fractional shortening (FS%), were evaluated by vevo-3100 high-resolution imaging system.

### **Western blot analysis**

Mouse tissues were homogenized in RIPA lysis buffer (#P0013C, Beyotime Biotechnology). Protein contents were measured using BCA assay (#P0012S, Beyotime Biotechnology). The proteins were separated by SDS-PAGE electrophoresis and subsequently electrotransferred to nitrocellulose membranes. After being blocked with a solution of 5% defatted milk in TBST (Tris buffered saline containing 0.05% Tween 20, pH 7.4) for 1.5 h at room temperature, the membranes were incubated with antibodies at 4 °C overnight. The membrane was washed three times with TBST solution before being incubated with the secondary antibody. Protein bands were detected by using enhanced chemiluminescence kits. Image J software was used to quantify the intensity of protein bands.

### **Histological and immunohistochemical ( IHC) analyses**

Tissue samples were fixed with 10% formalin, embedded in paraffin, sectioned to an 8 μm thickness, stained using hematoxylin and eosin (HE) and Masson's trichrome to assess the extent of tissue fibrosis. In addition, paraffin sections of heart were stained with Sirius Red and paraffin sections of liver were stained with Oil Red to appraise hepatic steatosis. Images were captured using Nikon Eclipse E100 ortho optical microscope (Nikon, Japan). For immunohistochemical experiments, paraffin sections were dewaxed and rehydrated. The tissue was put into citric acid antigen repair buffer for antigen repair, and then put into 3% hydrogen peroxide solution to eliminate endogenous peroxidase. Then the tissue sections were blocked with 3% BSA solution and incubated with anti-TNF-α or F4/80 antibody at 4 °C overnight. After incubating with HRP-labeled secondary antibody, the samples were visualized using DAB staining. Images were captured using XSP-C204 biomicroscope (Chongqing chongguang industry co., ltd, China).

### **Extraction of live microsomes and determination of P450 enzyme content**

Add 2.5 mL per gram PBS-Sucrose (0.25 M) buffer to the liver tissue samples and then liver tissue was homogenized. Samples were subsequently centrifuged at 11,000 rpm for 15 min at 4 °C. After the supernatant was taken, the centrifugation operation was repeated. Then the samples were centrifuged at 75600 xg in ultracentrifuge for 2 h at 10 °C. The precipitate was resuspended

with PBS until the solution was clear. We then determined the CYP450 content in the microsomal samples using the CO differential method. We took 1 mL of microsome samples which were diluted to 1 mg/mL with PBS, aerate with carbon monoxide for 2 min, and then added 5 mg of sodium hydrosulfite. The absorbance at 450 nm and 490 nm was measured by Evolution 201 ultraviolet-visible spectrophotometer (ThermoFisher scientific, USA). The calculation formula is:  $C \text{ (nmol/mL)} = (\text{OD } 450 \text{ nm} - \text{OD } 490 \text{ nm}) * 1000 / 91$ .

## Statistical analysis

All data are presented as mean  $\pm$  standard error of the mean (S.E.M). Statistical significance among groups was determined by Student's t-test for multiple comparisons or one-way analysis of variance (ANOVA). If the variance was uneven, welch correction was used. Differences between groups were considered to be statistically significant when  $P < 0.05$  (GraphPad Prism 6.0 and SPSS 22.0 softwares).

## Results

### The improvement of Cyy-287 on obesity-induced metabolic disorder

To confirm whether obesity will cause multiple organ damage, especially cardiac and hepatic dysfunction and evaluate the preventive effect of Cyy-287 treatment, we established a high-fat diet (HFD) mice model. After 20 weeks, mice fed with HFD showed a higher rate of weight gain ( $> 20 \text{ g}$ ) than mice fed with standard diet ( $< 5 \text{ g}$ ), and all their weight exceeded 45 g (**Fig. 1B**). The body mass index (BMI) of HFD mice was significantly increased compared with the control group ( $P < 0.0001$ ), but Cyy-287 treatment could not delay the increasing of BMI (**Fig. 1C**). In addition, the serum glucose level of mice in HFD group increased significantly ( $P < 0.001$ ), indicating the occurrence of hyperglycemia, and Cyy-287 significantly reduced blood glucose compared with HFD group (5 mg/kg,  $P < 0.01$ ; 20 mg/kg,  $P < 0.05$ ; **Fig. 1D**). What's more, Cyy-287 decreased serum lipid markers LDL (5 mg/kg,  $P < 0.01$ ; 20 mg/kg,  $P < 0.001$ ) and TC (5 mg/kg,  $P < 0.001$ ; 20 mg/kg,  $P < 0.0001$ ) in HFD mice (**Fig. 1E and 2F**). These results showed that Cyy-287 improved the metabolic disorder caused by obesity, including decreased serum glucose and decreased serum lipid production.

### The preventive effect of Cyy-287 on obesity-linked cardiac and hepatic dysfunction

The mice in the HFD group showed obvious ventricular remodeling characteristics, such as increased ventricular inner diameter and changed ejection fraction (EF,  $P < 0.001$ ) and fractional shortening (FS,  $P < 0.001$ ), confirming the cardiac dysfunction caused by obesity (**Fig. 2A-2C**). Cyy-287 significantly restored mice cardiac function indicators EF (20 mg/kg,  $P < 0.001$ ) and FS (20 mg/kg,  $P < 0.001$ ), and reduced cardiac hypertrophy index in a dose-dependent manner (**Table 1**). The levels of ALT and AST were also significantly increased in the HFD group compared with the control group ( $P < 0.0001$ ), confirming the hepatic dysfunction caused by obesity (**Fig. 2D and 2E**). Cyy-287 exhibited a remarkably suppressive effect on the elevation of serum ALT (5 mg/kg,  $P < 0.001$ ) and AST (5 or 20 mg/kg,  $P < 0.0001$ ). These outcomes corroborate Cyy-287's efficacy in impeding obesity-related deterioration of cardiac and hepatic functions.

### **Cyy-287 inhibits obesity-induced cardiac inflammation though suppressing MAPK/NF- $\kappa$ B pathway and activating AMPK pathway**

To further investigate the effect of Cyy-287 on obesity-induced cardiac dysfunction, we conducted HE and IHC staining. The analysis of the histopathological images showed that HFD caused cardiac morphological changes, including myocardial fiber atrophy and disorder, inflammatory cell infiltration, which were improved after Cyy-287 treatment (**Fig. 3A**). In addition, Cyy-287 treatment reduced the expression of TNF- $\alpha$  in HFD mice. We then evaluated the degree of myocardial fibrosis by Masson and Sirius Red staining in mice. As shown in **Fig. 3A-3C**, there was significant fibrous proliferation (Masson,  $P < 0.001$ ) and collagen deposition (Sirius Red,  $P < 0.05$ ) in the myocardium of HFD mice, and the progression of myocardial fibrosis was significantly blocked after Cyy-287 treatment (Masson, 20 mg/kg,  $P < 0.01$ ; Sirius Red, 20 mg/kg,  $P < 0.05$ ). Consistent with the results of IHC, western blot results showed that Cyy-287 improved the HFD-induced Collagen- I expression (20 mg/kg,  $P < 0.05$ ) (**Fig. 3D**). The HFD group demonstrated markedly elevated levels of phosphorylated p65 (RelA), a crucial subunit of NF- $\kappa$ B, as well as p38, a member of the MAPKs family. Conversely, treatment with Cyy-287 significantly attenuated the cardiac expression of phosphorylated p65 and p38 (20 mg/kg,  $P < 0.05$ ), as compared to the HFD-only group. Meanwhile, the phosphorylation of AMPK was greatly inhibited by HFD ( $P < 0.05$ ), and the cardiac expression of phosphorylated AMPK was effectively increased after Cyy-287 treatment ( $P = 0.30$ ). Hence, our findings imply

that Cyy-287 proficiently safeguarded the myocardium from harm via the modulation of MAPK/NF- $\kappa$ B and AMPK signaling cascades.

### **Cyy-287 relieves obesity induced liver damage and MAPK/NF- $\kappa$ B pathway protein expression and AMPK activity inhibition**

Examination of the histopathological illustrations unveiled the morphological alterations brought about by HFD in the liver, comprising hepatic steatosis, inflammatory responses within the hepatic lobules, centrilobular hepatocyte necrosis, and the presence of ballooned hepatocytes (**Fig. 4A**). Cyy-287 undoubtedly alleviated liver damage, and reduced liver cell necrosis and degeneration. In addition, the Masson (20 mg/kg,  $P < 0.01$ ) and F4/80 (20 mg/kg,  $P < 0.001$ ) staining showed that Cyy-287 could reduce hepatic fibrosis and macrophage infiltration compared to the HFD group (**Fig. 4B** and **4C**). Similar to the results in the heart, the phosphorylation of AMPK was greatly inhibited by HFD ( $P < 0.05$ ), and the hepatic expression of phosphorylated AMPK was effectively increased after Cyy-287 treatment (20 mg/kg,  $P < 0.05$ ; **Fig. 4D**). In addition, the hepatic expression of phosphorylated p65 and p38 was effectively decreased after Cyy-287 treatment compared to HFD-only group (20 mg/kg,  $P < 0.05$ ). In conclusion, our histological and western blot analyses substantiate that administering Cyy-287 orally thwarted the liver impairment and inflammation triggered by HFD.

### **Cyy-287 relieves obesity induced liver lipid storage and SREBP-1c expression**

SREBP-1c is a key regulatory transcription factor involved in *de novo* lipogenesis, and the over-expression of SREBP-1c was correlated with the lipid storage in the liver. The Oil Red staining showed that Cyy-287 could reduce fatty accumulation in liver induced by HFD (**Fig. 4A**). Furthermore, the HFD group exhibited a significantly elevated expression level of SREBP-1c compared to the control group ( $P < 0.05$ ; **Fig. 4D**). However, oral administration of Cyy-287 effectively curbed the hepatic expression of SREBP-1c in comparison to the HFD-only group (20 mg/kg,  $P < 0.05$ ). Our data categorically establish that the hepatoprotective influence of Cyy-287 owes to its lipid synthesis inhibitory attributes.

### **Cyy-287 restores the content of hepatic CYP450 enzymes**

As a kind of haemoglobin, cytochrome P450 enzymes (CYP450) participate in the metabolism of many substances, including endogenous substances, exogenous substances, and drugs. CYP450 exists mainly in liver microsomes and the activity of CYP450 can be used to evaluate the liver function. Hence, we extracted the mouse liver microsomes and quantify the total amount of

CYP450 enzymes. As shown in the **Fig. 5**, the content of hepatic CYP450 enzymes in HFD group mice was significantly reduced ( $P < 0.05$ ), and the reduction of liver CYP450 enzymes content induced by HFD was significantly reversed after Cyy-287 treatment (20 mg/kg;  $P < 0.05$ ), which further indicating that Cyy-287 could restore liver function and alleviated the liver injury caused by high fat.

## Discussion

Obesity, which has been rising in prevalence worldwide over the past several decades, is now considered a public health epidemic. Studies have found that obese people present a chronic low-grade inflammatory state with imbalance of pro-inflammatory and anti-inflammatory immune cells (Gregor & Hotamisligil, 2011). Obesity induced inflammation will lead to maladaptive responses such as fibrosis and necrosis that can cause significant tissue damage (Crewe, An & Scherer, 2017). Moreover, obesity induced inflammation is unique in that it involves multiple organs, including adipose, pancreas, liver, skeletal muscle, heart, and brain. Persistent metabolic inflammation also lead to serious syndrome, including insulin resistance, type 2 diabetes, cardiovascular disease, liver disease, cancer, and neurodegeneration (Saltiel & Olefsky, 2017). It has been reported that anti-inflammatory drugs or natural compounds can alleviate obesity-related metabolic diseases (Lee et al., 2020; Ngamsamer, Sirivarasai & Sutjarit, 2022). Consequently, blocking obesity-induced inflammation could be an effective way to prevent tissue damage and syndrome.

Here, we first demonstrated that cyy-287, a novel pyrimidine-2,4-diamine derivative, had a strong inhibitory effect on HFD induced inflammation and tissue injury. The NF- $\kappa$ B pathway is a critical signaling axis mediating the expression of inflammation-related mediators such as via NF- $\kappa$ B-binding motifs in their promoters (Dorrington & Fraser, 2019). NF- $\kappa$ B protein is mainly composed of two subunits, p50 and p65, which could be activated by cytokines, pathogens, and radiation (Liu, Zhang & Joo, 2017). In this study, we found that Cyy-287 can significantly inhibit NF- $\kappa$ B p65-mediated inflammatory pathway in heart and liver tissues of obese mice. Oral administration of Cyy-287 to HFD mice induced a noteworthy decline in the histopathological disruption of the heart and liver, characterized by attenuation in macrophage infiltration, fibrosis, and necrotic deterioration. Furthermore, Cyy-287 enhanced EF and FS and reduced the serum AST and ALT levels that ensue due to liver functional impairment induced by HFD. Additionally, Cyy-287 effectively curbed abnormal hepatic lipid aggregation (TG). Thus, our

data support the idea that Cyy-287 could effectively protect against the obesity-induced cardiac and hepatic damage via inhibiting the NF- $\kappa$ B mediated inflammatory pathway.

As a fundamental transducer of upstream signaling for NF- $\kappa$ B, the MAPKs family is intricately linked to cell death and is accountable for generating proinflammatory cytokines. Several studies have shown that MAPK is involved in oxidative stress and apoptosis, and blocking MAPK signaling pathway can prevent paracetamol-induced hepatotoxicity by regulating pro-inflammatory cytokines (Noh *et al.*, 2013). In addition, research suggested that curcumin reduces chemical and drug-induced cardiotoxicity by inhibiting p38 MAPK signaling pathway (Yarmohammadi, Hayes & Karimi, 2021). Our western blot data showed that HFD activated the expression of P-p38, leading to cardiomyocyte and hepatocyte injury. Cyy-287 effectively protected the heart and liver from damage by inhibiting the MAPK pathway.

As a highly conserved regulator of metabolism, AMPK is also a critical component in the prevention of various inflammatory signaling pathways, which may represent a larger therapeutic target for the control of insulin resistance, diabetes, and obesity (Noor *et al.*, 2020). A recent study showed that the CaMKK $\beta$ /LKB1/AMPK axis and Ca<sup>2+</sup> levels can provide a quick, adaptable switch to promote cell survival (Yang *et al.*, 2020). In addition, activation of AMPK alleviates paracetamol-induced hepatotoxicity by inhibiting the release of pro-inflammatory cytokines and abnormal lipid metabolism (Jiang *et al.*, 2021). In recent years, cardiomyopathy caused by obesity has attracted more and more attention. Studies have shown that upregulating the SIRT1/LKB1/AMPK pathway can reduce obesity-induced cardiomyopathy (Li *et al.*, 2022). Our findings evinced that the elevation in the phosphorylation of AMPK was elicited by the administration of Cyy-287. Additionally, our results highlighted that the administration of Cyy-287 repressed obesity-related cardiac and hepatic injury by upregulating the AMPK signaling pathway.

It is reported that the accumulation of liver fat will lead to inflammation and further liver damage. SREBP-1c is an important transcription factor in de novo lipogenesis and play a key role in regulating liver fat metabolism. The entry of SREBP-1c into the nucleus is regulated by AMPK (Chao *et al.* 2019). The western blot results showed that Cyy-287 could regulate AMPK-SREBP-1c signal pathway to improve metabolic disorders caused by HFD in liver. Oil Red staining results further confirmed that Cyy-287 alleviated the excessive accumulation of liver fat. In addition, the levels of lipid markers (LDL and TC) in HFD mice were decreased after Cyy-

287 treatment. Thus, our data suggested that Cyy-287 can effectively reduce liver lipid synthesis and fat accumulation in HFD mice by inhibiting SREBP-1c.

Unfortunately, our research still has some limitations. In this study, the specific mechanism of Cyy-287 changing AMPK activity has not been clarified, and the molecular mechanism has not been deeply studied. We will do further research in the follow-up study.

## Conclusions

In this paper, we provided evidence that Cyy-287 has a significant therapeutic effect on obesity-induced heart and liver damage by inhibiting inflammatory response and lipogenesis in HFD mice. The mechanisms of action were revealed to involve Cyy-287's potent anti-inflammatory properties, mediated by inhibiting the NF- $\kappa$ B and MAPK signaling pathways; activating AMPK signalling pathways; and suppressing liver lipid synthesis (**Fig. 6**). Therefore, Cyy-287 has the potential to be a therapeutic drug to reduce the complications of obesity.

# Figure legends

## Figure1. Cyy-287 restrains the occur of hyperglycosemia and hyperlipidemia

induced by HFD in mice. (A) The chemical structure of cyy-287. (B) Body weight changes in mice. (C) The BMI of mice ( $n \geq 7$ ). The serum glucose level ( $n \geq 7$ ) (D), lipid markers LDL ( $n=3$ ) (E) and TC ( $n=3$ ) (F) of mice treated under different conditions was measured. Data are presented as the mean  $\pm$  SEM. \*\*\*  $P < 0.001$ , \*\*\*\*  $P < 0.0001$  compared with the control group. #  $P < 0.05$ , ##  $P < 0.01$ , ###  $P < 0.001$ , ####  $P < 0.0001$  compared with the HFD group.

## Figure2. Cyy-287 improves cardiac and hepatic dysfunction induced by HFD in

mice. (A) Representative mechocardiography M-mode images in mice. (B and C) Quantification of cardiac function indexes ( $n=5$ ). (D and E) Determination of AST and ALT ( $n \geq 6$ ). Data are presented as the mean  $\pm$  SEM. \*\*\*  $P < 0.001$ , \*\*\*\*  $P < 0.0001$  compared with the control group. ###  $P < 0.001$ , ####  $P < 0.0001$  compared with the HFD group.

## Figure3. Cyy-287 attenuates myocardial inflammation and fibrosis by inhibiting

p38 MAPK and activating AMPK in HFD mice. (A) Tissue sections were analysed by HE, Masson, and Sirius Red and IHC using anti-TNF- $\alpha$  antibody (scale bar: 50  $\mu$ m). (B and C) Quantitative data of Masson and Sirius Red staining in (A). (D) Proteins were extracted from myocardium and then subject to western blot analysis. Quantified results were plotted. Data are presented as the mean  $\pm$  SEM ( $n=3$ ). \*  $P < 0.05$ , \*\*\*  $P < 0.001$  compared with the control group. #  $P < 0.05$ , ##  $P < 0.01$  compared with the HFD group.

## Figure4. Cyy-287 mitigates hepatic fat accumulation and damage though p38

MAPK/NF- $\kappa$  B dowregulation and activating AMPK in HFD mice. (A) Tissue sections were analysed by HE, Oil Red, and Masson and IHC using F4/80 anti-body (scale bar: 50  $\mu$ m). (B and C) Quantitative data of Masson and F4/80 in (A). (D) Proteins were extracted from myocardium and then subject to western blot analysis. Quantified results were plotted. Data are presented as the mean  $\pm$  SEM ( $n=3$ ). \*  $P < 0.05$ , \*\*\*\*  $P < 0.0001$  compared with the control group. #  $P < 0.05$ , ##  $P < 0.01$ , ###  $P < 0.001$  compared with the HFD group.

**Figure5. Cyy-287 increases the content of CYP450 enzymes in liver microsomes of HFD mice.** (A) Representative UV chromatograms of liver microsomes. (B) Quantification of liver microsomal content. Data are presented as the mean  $\pm$  SEM (n=3). \*  $P < 0.05$  compared with the control group. #  $P < 0.05$  compared with the HFD group.
