Background. Hypertension stands as the leading single contributor to the worldwide burden of mortality and disability. Limited evidence exists regarding the association between the combined healthy lifestyle score (HLS) and hypertension control in both treated and untreated hypertensive individuals. Therefore, we aimed to investigate the association between HLS and hypertension control among adults with treated and untreated hypertension. **Methods.** This cross-sectional study, including 311,994 hypertension patients, was conducted in Guangzhou using data from the National Basic Public Health Services Projects in China. The HLS was defined based on five low-risk lifestyle factors: healthy dietary habits, active physical activity, normal body mass index, never smoking, and no alcohol consumption. Controlled blood pressure was defined as systolic blood pressure <140 mmHg and diastolic blood pressure < 90 mmHg. A multivariable logistic regression model was used to assess the association between HLS and hypertension control after adjusting for various confounders. **Results.** The HLS demonstrated an inverse association with hypertension control among hypertensive patients. In comparison to the low HLS group (scored 0-2), the adjusted odds ratios (95% confidence intervals) for hypertension were 0.76 (0.74, 0.78), 0.59 (0.57, 0.60), and 0.48 (0.46, 0.49) for the HLS groups scoring 3, 4, and 5, respectively ($P_{\text{trend}} < 0.001$). Notably, an interaction was observed between HLS and antihypertensive medication in relation to hypertension control ($P_{\text{interaction}} < 0.001$). When comparing the highest HLS (scored 5) with the lowest HLS (scored 0-2), adjusted ORs were 0.50 (0.48, 0.52, $P_{\text{trend}} < 0.001$) among individuals who self-reported using antihypertensive medication and 0.41 (0.38, 0.44, $P_{\text{trend}} < 0.001$) among those not using such medication. Hypertensive patients adhering to a healthy lifestyle without medication exhibited better blood pressure management than those using medication while following a healthy lifestyle. **Conclusion.** HLS was

associated with a reduced risk of uncontrolled blood pressure.

21 **Abstract**

22 **Background.** Hypertension stands as the leading single contributor to the worldwide burden of
23 mortality and disability. Limited evidence exists regarding the association between the combined
24 healthy lifestyle score (HLS) and hypertension control in both treated and untreated hypertensive
25 individuals. Therefore, we aimed to investigate the association between HLS and hypertension
26 control among adults with treated and untreated hypertension.

27 **Methods.** This cross-sectional study, including 311,994 hypertension patients, was conducted in
28 Guangzhou using data from the National Basic Public Health Services Projects in China. The
29 HLS was defined based on five low-risk lifestyle factors: healthy dietary habits, active physical
30 activity, normal body mass index, never smoking, and no alcohol consumption. Controlled blood
31 pressure was defined as systolic blood pressure <140 mmHg and diastolic blood pressure < 90
32 mmHg. A multivariable logistic regression model was used to assess the association between
33 HLS and hypertension control after adjusting for various confounders.

34 **Results.** The HLS demonstrated an inverse association with hypertension control among
35 hypertensive patients. In comparison to the low HLS group (scored 0-2), the adjusted odds ratios
36 (95% confidence intervals) for hypertension were 0.76 (0.74, 0.78), 0.59 (0.57, 0.60), and 0.48
37 (0.46, 0.49) for the HLS groups scoring 3, 4, and 5, respectively ($P_{\text{trend}} < 0.001$). Notably, an
38 interaction was observed between HLS and antihypertensive medication in relation to
39 hypertension control ($P_{\text{interaction}} < 0.001$). When comparing the highest HLS (scored 5) with the
40 lowest HLS (scored 0-2), adjusted ORs were 0.50 (0.48, 0.52, $P_{\text{trend}} < 0.001$) among individuals
41 who self-reported using antihypertensive medication and 0.41 (0.38, 0.44, $P_{\text{trend}} < 0.001$) among
42 those not using such medication. Hypertensive patients adhering to a healthy lifestyle without
43 medication exhibited better blood pressure management than those using medication while

44 following a healthy lifestyle.

45 **Conclusion.** HLS was associated with a reduced risk of uncontrolled blood pressure.

46

47 **INTRODUCTION**

48 Hypertension stands as the most significant contributor to the global burden of mortality and
49 disability (*Poulter et al., 2015*). Between 1990 and 2019, the number of individuals aged 30-79
50 with high blood pressure doubled, reaching around 626 million females and 652 million males
51 living with hypertension worldwide by 2019 (*NCD-RisC, 2021*). Approximately 75% of people
52 with hypertension reside in low- and middle-income nations (*Mills et al., 2016*). The prevalence
53 of hypertension among Chinese adults has consistently increased with urbanization and the aging
54 of the population (*Wang et al., 2018*). Despite hypertension management being a national public
55 health priority, the blood pressure control rate remains low, estimated at 7.2% in China from
56 2014 to 2017 (*Lu et al., 2017*). Identifying effective strategies for hypertension management is
57 crucial.

58 Various aspects of individual lifestyle factor, such as dietary habits, physical activity, body
59 mass index (BMI), smoking, and alcohol consumption, have been independently demonstrated to
60 influence blood pressure levels. Studies suggests that maintaining a healthy dietary habits,
61 engaging in regular exercise, maintaining a normal BMI, never smoking, and reducing alcohol
62 consumption are beneficial for hypertension control (*Chudek et al., 2021; Lopes et al., 2020; Niu*
63 *et al., 2021; Ozemek et al., 2018; Roerecke et al., 2017*). However, these studies have ignored
64 the fact that multiple lifestyle-related factors often coexist in individuals, collectively affecting
65 people's physical health (*Aleksandrova et al., 2014; Erben et al., 2019*). Thus, it is essential to
66 consider these lifestyle factors simultaneously, along with their combined consequences.

67 Previous studies conducted across diverse nations consistently indicate that adherence to
68 healthy lifestyle practices is associated with a decreased risk of various diseases, including
69 hypertension, type 2 diabetes, early-onset dementia, bladder cancer, and cardiometabolic

70 multimorbidity (*He et al., 2023a; He et al., 2023b; Li et al., 2023; Xie et al., 2022; Zhen et al.,*
71 *2023*). Notably, studies conducted in China, Iran, Japan, and America have demonstrated the
72 association between a healthy lifestyle and reduced blood pressure (*Akbarpour et al., 2018;*
73 *Appel et al., 2003; Xiao et al., 2020; Yokokawa et al., 2014*). However, the sample sizes of
74 studies exploring the relationship between a healthy lifestyle and hypertension control vary from
75 a few hundred to a few thousand, and there is a lack of studies in large sample populations.

76 The effective management of hypertension often relies on the pivotal role of
77 antihypertensive medication treatment. However, the use of anti-hypertensive drugs may lead to
78 decreased adherence to healthy lifestyles (*Neutel & Campbell, 2008*). So far, some studies have
79 evaluated the relationship between combined lifestyle factors and hypertension control in
80 individuals undergoing treatment (*Cherfan et al., 2020; Yokokawa et al., 2014*). The association
81 between lifestyle factors and blood pressure control has also been explored in untreated
82 hypertensive patients (*Appel et al., 2003*). However, few studies have simultaneously evaluated
83 the association between lifestyle behavior and hypertension control among both treated and
84 untreated hypertensive patients (*Akbarpour et al., 2018*), which could be an important step in
85 blood pressure management. To our knowledge, only a cross-sectional study in Iran has
86 investigated the relationship between a healthy lifestyle and hypertension control among those
87 aware and using antihypertensive medications and those aware but not taking medication
88 (*Akbarpour et al., 2018*). However, this study had a limited sample size and did not include
89 individuals aged over 65 years. Additionally, there are no related studies in China.

90 To address these knowledge gaps, our objective was to examine the association of a healthy
91 lifestyle score (HLS), encompassing dietary habits, physical activity, BMI, smoking, and alcohol
92 consumption, with hypertension control among both treated and untreated hypertensive patients

93 in China.

94 **METHODS**

95 **Study population**

96 The study enrolled hypertensive patients receiving the National Basic Public Health Services in
97 Guangzhou in 2018. The National Basic Public Health Services projects represent the
98 fundamental healthcare services provided by the government free of charge to all residents,
99 addressing primary health issues among urban and rural populations. These services primarily
100 focus on children, pregnant women, the elderly, and patients with chronic diseases (*Wang et al.*,
101 2019).

102 A total of 375,912 hypertensive patients were enrolled in this study. The inclusion criteria
103 were as follows: aged ≥ 35 years, Guangdong natives or residents who had lived in Guangzhou
104 for at least six months, primary hypertension diagnosis, and undergoing a physical examination.
105 Hypertension was defined as systolic blood pressure (SBP) ≥ 140 mm Hg or diastolic blood
106 pressure (DBP) ≥ 90 mm Hg, or reporting current use of antihypertensive medication, or self-
107 reported hypertension (*Cao et al.*, 2021). Exclusion criteria included repeat participants
108 ($n=13,284$); individuals with missing or incomplete blood pressure information ($n=10,343$);
109 those with missing or incomplete lifestyle factor information ($n=11,079$), participants with
110 extreme blood pressure values ($n=20,672$), and individuals with extreme values in lifestyle
111 factors ($n=8540$). Ultimately, 311,994 participants were included in the final data analysis (Fig.
112 1). Supplementary Table S1 compares the characteristics of both the excluded participants and
113 those included in the study. Extreme values were defined as below the first quartile (Q1) minus
114 1.5 times the interquartile range or above the third quartile (Q3) plus 1.5 times interquartile range
115 (*Haileslasie et al.*, 2020).

116 This research was conducted in accordance with the ethical standards outlined in the 1964
117 Declaration of Helsinki and received approval from the Ethics Committee of the School of
118 Public Health at Sun Yat-Sen University (approval number: 2023-007).

119 **Data collection**

120 All participants underwent face-to-face interviews conducted by trained medical staff at
121 community-level health facilities using a structured questionnaire. The collected information
122 included socio-demographic characteristics (age, sex, ethnicity, educational level, marital status),
123 lifestyle factors (dietary habits, physical activity, smoking, and alcohol consumption), history of
124 diabetes, family history of hypertension, and medication details. Dietary habits were divided into
125 balanced meat and vegetable, meat-based, vegetarian-based, salt-loving, oil-loving, and sugar-
126 loving. Physical activity levels were assessed based on exercise frequency, categorized as never,
127 occasional, more than once a week, and daily. Occasional and more than once a week were
128 calculated based on once a week and three times a week, respectively. Smoking status was
129 classified as never smokers and smokers (former and current smokers). Never smokers were
130 participants who reported never smoking, while smokers included participants who reported
131 current smoking and ever smoking (*Yao et al., 2019*). Similarly, drinking status was divided into
132 never drinkers and drinkers (ever and current drinkers). Never drinkers were defined as
133 participants who reported never drinking, while drinkers included participants who reported
134 current drinking and former drinking (*Zhao et al., 2021*).

135 Standardized methods were used to measure participants' height and weight. BMI was
136 calculated by dividing body weight (in kilograms) by the square of height (in meters). According
137 to the Working Group on Obesity in China, underweight, normal weight, overweight, and
138 obesity were defined as BMI <18.5, 18.5–23.9, 24.0–27.9, and ≥ 28.0 kg/m², respectively (*Yuan*

139 *et al., 2017*).

140 Blood pressure was assessed with a single measurement, averaging readings from the left
141 and right arms. The measurement utilized upper-arm electronic medical blood pressure monitors
142 certified according to International Standard Protocols (*Xu et al., 2022*). Systolic and diastolic
143 blood pressure were measured in the seated position for both arms. The mean value of the two
144 measurements from the left and right arms was considered as an individual's blood pressure
145 measurements. Controlled hypertension was defined as mean SBP <140 mm Hg and mean DBP
146 <90 mm Hg (*Kimani et al., 2019*). Uncontrolled hypertension was defined as mean SBP \geq 140
147 mm Hg and/or mean DBP \geq 90 mm Hg (*Yokokawa et al., 2011*).

148 **Definition of healthy lifestyle score**

149 Drawing upon previous knowledge and contemporary public health recommendations, we
150 formulated a HLS using information regarding five lifestyle factors: dietary habits, physical
151 activity, BMI, smoking, and alcohol consumption (*Fukunaga et al., 2020; Ye et al., 2021*).
152 Participants were assigned 1 point for each of the following protective lifestyle factors: healthy
153 dietary habits (balanced meat and vegetable, moderate salt consumption, moderate oil
154 consumption, and moderate added sugar consumption) (*Che et al., 2023*), active physical activity
155 (exercise frequency \geq 2 times weekly) (*Yokokawa et al., 2014*), normal BMI (18.5-23.9 kg/m²)
156 (*Wang et al., 2022*), never smoking (*Li et al., 2021*), and no alcohol consumption (*Che et al.,*
157 *2023*). The details of the lifestyle score are outlined in Table 1. These five scores were summed
158 to generate a final low-risk lifestyle score ranging from 0 to 5, with lower scores indicating a less
159 healthy lifestyle.

160 **Statistical analysis**

161 We divided the HLS into five groups (0-2, 3, 4, and 5). Due to the small number of participants

162 with HLS scores of 0 and 1 (n = 263 and 4886, respectively), we combined the three lowest
163 categories, considering those with HLS of 0-2 as the reference category in all analyses.
164 Categorical variables are expressed as numbers (percentages). Basic characteristics of controlled
165 and uncontrolled hypertension were compared using chi-square tests for categorical variables. A
166 multivariate logistic regression model was used to estimate odds ratio (OR) and 95% confidence
167 intervals (CI) for the analysis of the relationship between HLS and hypertension control, with
168 participants following an unhealthy lifestyle as the reference. The multivariable model was
169 adjusted for all potential confounders, including age, sex, ethnicity, educational level (primary
170 school or below, junior high school, senior high school, college or above, and unknown), marital
171 status, history of diabetes, family history of hypertension, and self-reported using
172 antihypertensive medication.

173 Stratified analyses were conducted by antihypertensive drugs use (reporting no use of
174 antihypertensive medication vs. reported using antihypertensive medication). The significance of
175 differences in effects between subgroups was tested using the formula: $z = (\beta_1 - \beta_2)$
176 $\sqrt{(SE_1)^2 + (SE_2)^2}$, where β_1 and β_2 indicate the estimates for each subgroup, and SE_1 and SE_2
177 represent their respective standard errors (*Altman & Bland, 2003*). Interaction refers to the
178 variations in the response magnitude observed across different levels of a specific factor
179 (*McCabe et al., 2022*). We calculated it by including interaction terms in the multiple regression
180 model. To assess the association of each component of the HLS with hypertension control, we
181 constructed univariate adjustment models controlling for the above covariates, as well as the
182 other components of the HLS for each component.

183 All statistical analysis were performed using R x64 4.1.1. Statistical significance was
184 determined at a two tailed P value of less than 0.05.

185

186 **RESULTS**187 **Baseline characteristics**

188 As shown in Table 2, of the 311,994 participants, 243,101 (77.92%) were 65 years and older,
189 124,116 (39.78%) were males, and 256,328 (82.16%) reported using antihypertensive
190 medication. In comparison to treated patients, untreated individuals were more likely to be older,
191 exhibit higher proportions of males, and have lower educational attainment. Participants
192 reporting no use of antihypertensive medication were also more likely to have a lower BMI,
193 engage in less physical activity, alcohol consumption, possess a lower HLS, report a lower
194 history of diabetes, and have less family history of hypertension than those who reported using
195 antihypertensive medication. There was no significant difference in ethnicity ($P = 0.572$), marital
196 status ($P = 0.195$), dietary habits ($P = 0.214$), and smoking ($P = 0.117$).

197 **Association of HLS with hypertension control**

198 Table 3 shows the association of HLS with hypertension control. In comparison to patients with
199 an HLS score of 0-2, the multivariable adjusted ORs and 95% CIs for those with a score of 3, 4,
200 and 5 were 0.76 (0.74, 0.78), 0.59 (0.57, 0.60), and 0.48 (0.46, 0.49; $P_{\text{trend}} < 0.001$), respectively.
201 Stratified analysis revealed an interaction between self-reported using antihypertensive
202 medication and HLS concerning hypertension control ($P_{\text{interaction}} < 0.001$). Comparing the highest
203 HLS (scored 5) with the lowest HLS (scored 0-2), the adjusted OR (95% CIs) was 0.50 (0.48,
204 0.52, $P_{\text{trend}} < 0.001$) in individuals reporting no use of antihypertensive medication and 0.41 (0.38,
205 0.44, $P_{\text{trend}} < 0.001$) in those who reported using antihypertensive medication (Table 4).
206 Compared to individuals who self-reported using antihypertensive medication, those not using
207 such medication exhibited stronger associations between HLS and the risk of uncontrolled

208 hypertension (all P for comparison <0.001). Hypertensive patients adhering to a healthy lifestyle
209 without medication demonstrated better blood pressure management than those who used
210 medication while following a healthy lifestyle.

211 **Association of individual lifestyle factors with hypertension control**

212 The associations between individual lifestyle factors, HLS, and controlled hypertension are
213 described in Fig. 2. Healthy dietary habits, active physical activity, normal BMI, never smoking,
214 and no alcohol consumption were independently associated with a negative correlation with
215 blood pressure control. Moreover, individuals who adopted all five healthy lifestyle factors
216 exhibited better blood pressure control compared to those adopting only a single factor. Similarly,
217 subgroup analysis by antihypertensive drugs use showed that healthy dietary habits, active
218 physical activity, normal BMI, never smoking and no alcohol consumption were associated with
219 well-controlled blood pressure.

220 **DISCUSSION**

221 The results indicated an inverse association between HLS and hypertension control among
222 hypertensive patients. Hypertensive patients adhering to a healthy lifestyle without taking
223 medication demonstrated better blood pressure management than those who used medication and
224 followed a healthy lifestyle.

225 We observed a strong inverse association between HLS and hypertension control. Our
226 findings align with the results of Akbarpour *et al.*, who reported that the risk of uncontrolled
227 hypertension in individuals with an unhealthy lifestyle was approximately 37% higher than in
228 those adhering to a moderate lifestyle (Akbarpour *et al.*, 2018). A cross-sectional study
229 conducted in France revealed that modifiable unhealthy lifestyle factors were associated with an
230 increased risk of uncontrolled hypertension, particularly in treated hypertensive subjects

231 (*Cherfan et al., 2020*). The FRESH study in Japan reported that maintaining a healthy lifestyle
232 served as a protective factor for blood pressure management (*Yokokawa et al., 2011; Yokokawa*
233 *et al., 2014*). In a Chinese Community Intervention Trial, the rate of blood pressure control
234 improved by 56.1% following a one-year lifestyle intervention (*Xiao et al., 2020*). Additionally,
235 in the PREMIER clinical trial involving 810 participants with nonoptimal blood pressure, a 6-
236 month lifestyle intervention comprising weight loss, sodium restriction, enhanced physical
237 activity, alcohol intake restriction, and improved diet quality significantly reduced SBP by 4.3
238 mmHg (*Appel et al., 2003*). Our findings align with this existing body of evidence, confirming
239 that a higher HLS is linked to a reduced risk of uncontrolled hypertension. These cumulative
240 findings underscore the pivotal role of lifestyle factors in the successful management of
241 hypertension. Therefore, integrating this combined evidence can inform the development and
242 implementation of impactful lifestyle intervention strategies, offering potential advancements in
243 hypertension management.

244 Our study revealed that 82.16% of hypertensive patients were self-reported using
245 antihypertensive medication. Patients who used medication and adhered to a healthy lifestyle
246 exhibited worse blood pressure control than those who adhered to a healthy lifestyle without
247 medication. Several possible explanations exist for the poorer blood pressure control in
248 individuals adhering to a healthy lifestyle while using antihypertensive drugs. Firstly, in our
249 study, the prevalence of diabetes and family history of hypertension was higher in hypertensive
250 patients using medication than in those not using medication. Secondly, individuals not taking
251 medication may have lower blood pressure levels than those taking medication (*Akbarpour et al.,*
252 *2018*). Lastly, the lower adherence among people taking medication may contribute to
253 uncontrolled hypertension (*Macquart de Terline et al., 2020*). To our knowledge, only one study

254 has concurrently examined the relationship between HLS and blood pressure control among
255 treated and untreated hypertensive patients (*Akbarpour et al., 2018*). A cross-sectional study in
256 Iran, including 2577 participants with hypertension, found that the risk of uncontrolled
257 hypertension in individuals with good lifestyle behaviors was 1% and 45% lower than those with
258 poor lifestyle behaviors among treated and untreated hypertensive patients, respectively.
259 However, the study's findings were not statistically significant, possibly due to the relatively
260 small sample size (*Akbarpour et al., 2018*). Additionally, the Dongfeng-Tongji cohort study in
261 China demonstrated that patients adhering to a healthy lifestyle but not using medications had a
262 lower mortality rate than patients using drugs and adhering to a healthy lifestyle (*Lu et al., 2022*).
263 This highlights the significance of promoting a healthy lifestyle, especially for individuals whose
264 blood pressure remains inadequately controlled despite the use of antihypertensive medications.
265 In managing hypertensive patients, healthcare professionals should prioritize lifestyle
266 interventions, complementing pharmacological management, to improve blood pressure control,
267 particularly for those with suboptimal outcomes even with antihypertensive drug therapy.

268 The analysis investigating blood pressure control in relation to individual lifestyle factors
269 indicated that healthy dietary habits, active physical activity, normal BMI, never smoking, and
270 no alcohol consumption were independently and inversely correlated with uncontrolled
271 hypertension. These findings align with previous studies examining the associations between
272 individual lifestyle factors and hypertension control (*Börjesson et al., 2016; Foti et al., 2022;*
273 *Kudo et al., 2015; Qin et al., 2021; Yang et al., 2022*). The present study contributes to the
274 evidence that healthy dietary habits, active physical activity, normal BMI, and never smoking,
275 and no alcohol consumption contribute to blood pressure management. Our findings also
276 demonstrated that individuals who adopted all five healthy lifestyle factors had better blood

277 pressure control than those who adopted only a single lifestyle factor. A study involving 1018
278 Irish adults revealed that individuals with four or more protective lifestyles had a lower risk of
279 developing hypertension than those with a single lifestyle (*Villegas et al., 2008*). The Aerobics
280 Center Longitudinal Study found that individuals with only a single lifestyle were more likely to
281 develop hypertension than those with five healthy lifestyles (*Banda et al., 2010*). This study,
282 along with previous studies, indicates that the HLS serves as a composite indicator, capturing an
283 individual's overall commitment to a healthy lifestyle. It emphasizes the cumulative impact of
284 multiple healthy lifestyle factors on blood pressure management.

285 Our study possesses certain strengths. Firstly, a key advantage of this study lies in its
286 extensive sampling of Chinese adults with hypertension. Furthermore, the investigation explores
287 the relationship between HLS and blood pressure control across both treated and untreated
288 hypertensive patient groups.

289 Nevertheless, this study is subject to several limitations. Firstly, a large number of
290 participants were excluded due to incomplete data, which could lead to selection bias and impact
291 the generalizability of our findings. The findings may be more applicable to middle-aged and
292 elderly patients with hypertension. Secondly, the potential for recall bias exists due to self-
293 reported lifestyle factors. Despite efforts to minimize this bias through professional training of
294 health workers, it cannot be completely ruled out. Thirdly, the reliability and validity of the HLS
295 were not evaluated. Future studies could conduct reliability tests or focus on direct assessments
296 of diet, physical activity, and other lifestyle factors, alongside BMI, to enhance the accuracy and
297 reliability of the HLS. Fourthly, the definition of healthy dietary habits relied on simple dietary
298 habits due to a lack of data on nutrient intake. The evaluation of various nutrient intakes,
299 particularly sodium, which significantly influences blood pressure, was not possible. Therefore,

300 our definition of healthy dietary habits may be specific to our study population, and
301 generalization of results could be limited. However, a cohort study in Japan also defined a
302 healthy eating factor based on dietary habits (*Yokokawa et al., 2014*). Fifthly, the inherent
303 reverse-causality bias in cross-sectional analyses prevents confirmation of a causal association
304 between a healthy lifestyle and controlled hypertension. Sixthly, although we addressed
305 confounding bias through adjustments in the multivariate mixture model and stratified analysis.
306 Residual confounders may persist since certain critical variables, such as hypertension duration
307 and medication adherence, were not considered. Seventhly, our definition of controlled blood
308 pressure relies on a single measurement rather than the average of multiple measurements.
309 However, we measured blood pressure in both arms and averaged the readings. Lastly, as our
310 study is cross-sectional, information on lifestyle and medications was collected only once at
311 baseline. The investigation of the relationship between changes in lifestyle, medication
312 utilization, and blood pressure control would require prospective studies.

313

314 **CONCLUSIONS**

315 This study demonstrated that a healthier lifestyle was associated with a reduced risk of
316 uncontrolled blood pressure. Additionally, individuals who adhered to a healthy lifestyle without
317 taking medication exhibited better blood pressure management compared to those using
318 medication while following a healthy lifestyle. Adoption of a healthy lifestyle is critical for
319 improving blood pressure levels, especially in those with inadequate blood pressure control
320 despite self-reported using antihypertensive drug. The results of this study could draw public
321 attention to lifestyles factors and offer evidence for the management of hypertension, guiding the
322 development of prevention and therapeutic strategies. Additional prospective studies are

323 warranted to confirm our findings and assess the impact of lifestyle changes on blood pressure
324 control in individuals with hypertension.

325 **ACKNOWLEDGMENTS**

326 We gratefully acknowledge the participation and contribution of the participants; without them,
327 this study would not have been possible.

539 **Fig. 2 Association between controlled hypertension and individual lifestyle factors and HLS.**

540 Dietary habits, physical activity, body mass index, smoking and alcohol consumption factors

541 with a score of 0 and HLS with a score of 0-2 were used as reference groups. Adjusted for age,

542 sex, ethnicity, educational level, marital status, history of diabetes, family history of

543 hypertension, self-reported using antihypertensive drugs, as well as other components of healthy

544 lifestyle score. Stratified factors were not adjusted in each model. HLS, healthy lifestyle score.

545

Figure 1

Fig. 1 Flow chart of study participants' recruitment

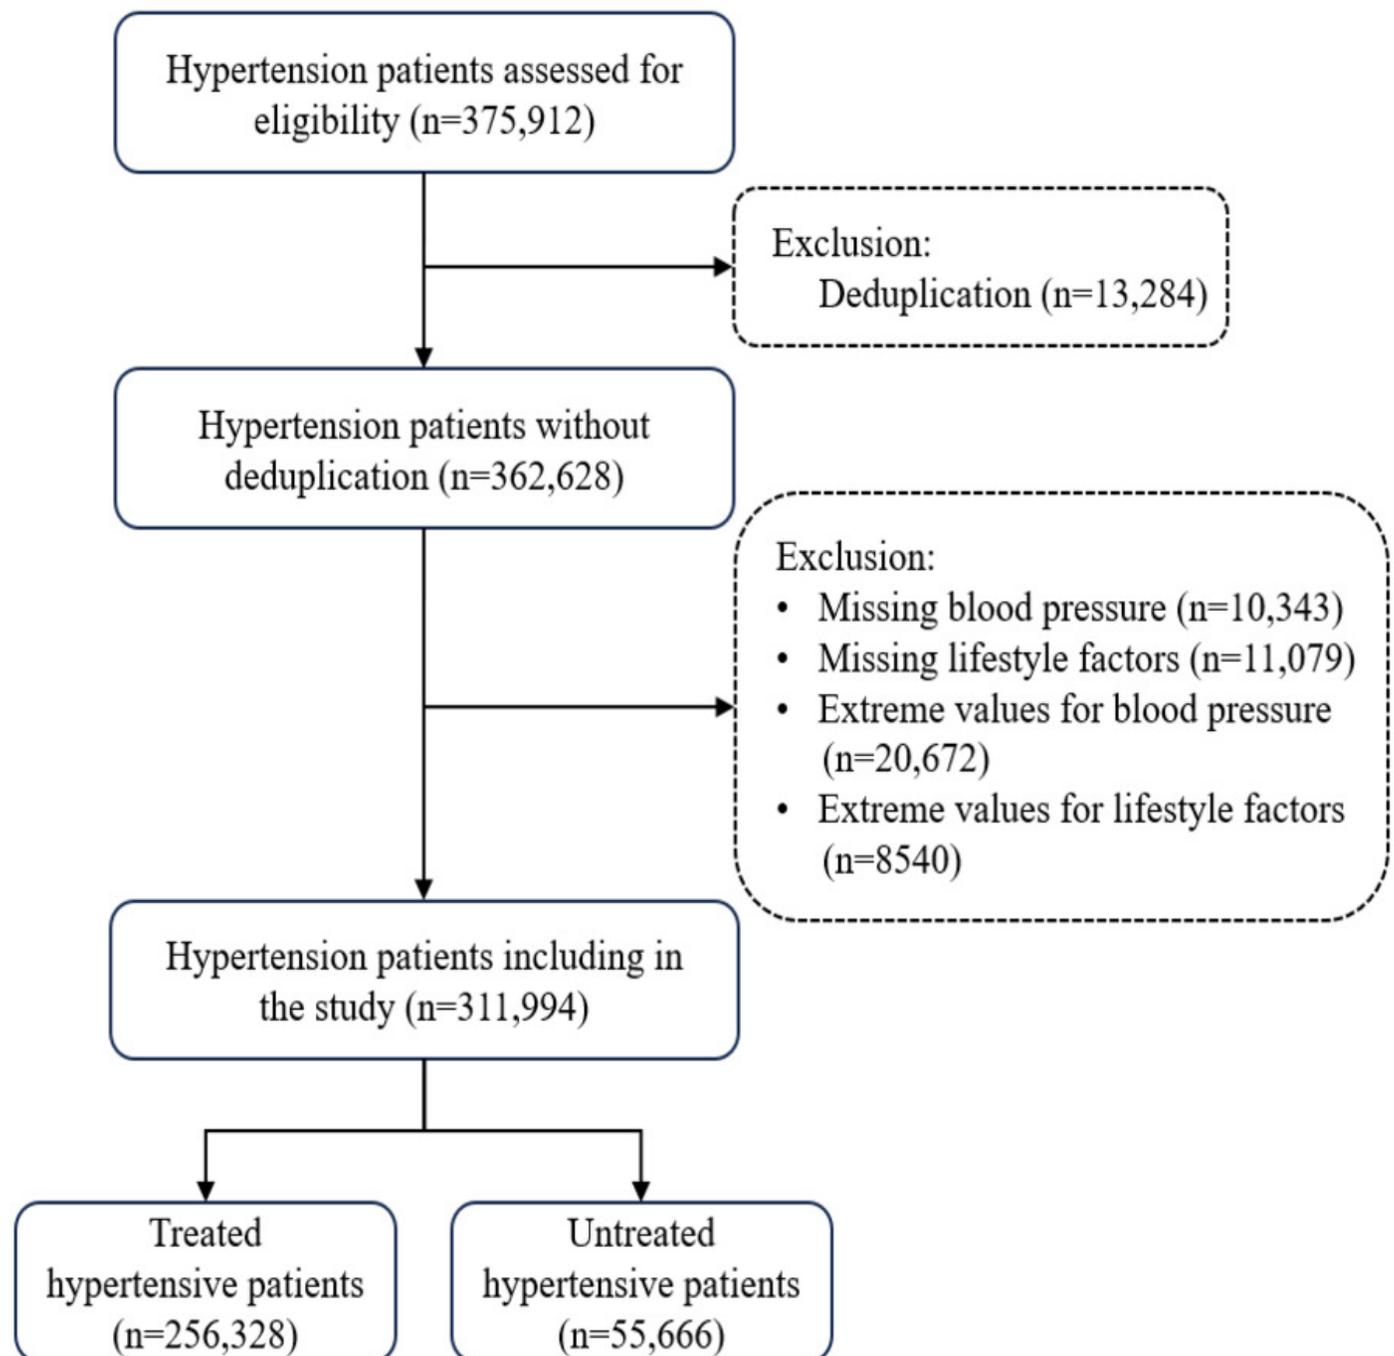

Figure 2

Fig. 2 Association between controlled hypertension and individual lifestyle factors and HLS

Dietary habits, physical activity, body mass index, smoking and alcohol consumption factors with a score of 0 and HLS with a score of 0-2 were used as reference groups. Adjusted for age, sex, ethnicity, educational level, marital status, history of diabetes, family history of hypertension, antihypertensive drugs use, as well as other components of healthy lifestyle score. Stratified factors were not adjusted in each model; HLS, healthy lifestyle score.

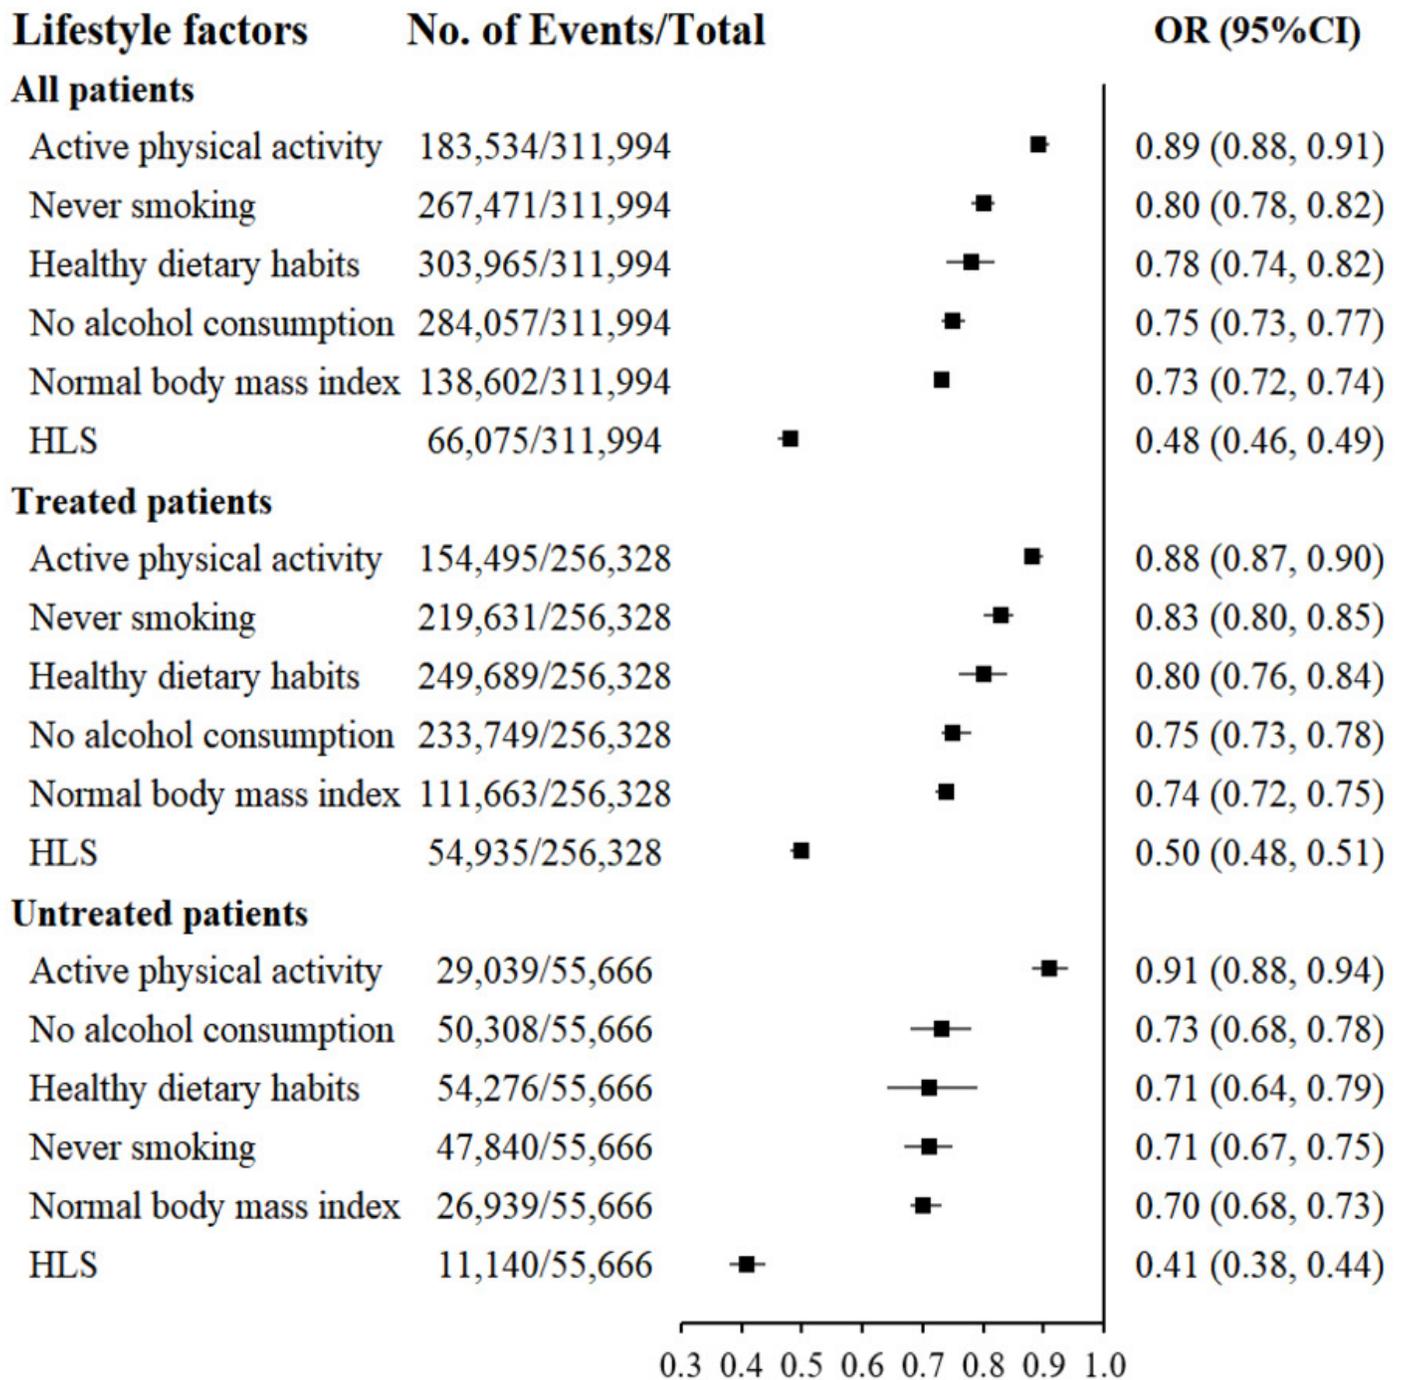

Table 1 (on next page)

Table 1 Components of lifestyle score

1 **Table 1 Components of lifestyle score**

Lifestyle factors	Category	Healthy/Unhealthy	Score
Dietary habits	Balanced consumption of meat and vegetable, moderate salt consumption, moderate oil consumption, and moderate added sugar consumption	Healthy	1
	Prefer meat/prefer vegetarian diet/high salt consumption/high oil consumption/high added sugar consumption	Unhealthy	0
Physical activities	Exercise frequency ≥ 2 times weekly	Healthy	1
	Exercise frequency < 2 times weekly	Unhealthy	0
Body Mass Index	18.5–23.9 kg/m ²	Healthy	1
	< 18.5 kg/m ² / ≥ 24.0 kg/m ²	Unhealthy	0
Smoking	Never	Healthy	1
	Current/former	Unhealthy	0
Alcohol consumption	Never	Healthy	1
	Current/former	Unhealthy	0

2

Table 3 (on next page)

Table 3 Association of healthy lifestyle score with hypertension control

1 **Table 3** Association of healthy lifestyle score with hypertension control

	Healthy Lifestyle Score				P_{trend}
	0-2	3	4	5	
Total					
No of patients	24,863	81,284	139,772	66,075	
Model 1 ^a	1.00	0.84 (0.82, 0.87)	0.66 (0.64, 0.67)	0.53 (0.52, 0.55)	<0.001
Model 2 ^b	1.00	0.76 (0.74, 0.78)	0.59 (0.57, 0.60)	0.48 (0.46, 0.49)	<0.001
Untreated					
No of patients	4633	15,061	24,832	11,140	
Model 1 ^a	1.00	0.72 (0.68, 0.77)	0.55 (0.52, 0.59)	0.46 (0.43, 0.49)	<0.001
Model 2 ^c	1.00	0.65 (0.61, 0.70)	0.49 (0.46, 0.52)	0.41 (0.38, 0.44)	<0.001
Treated					
No of patients	20,230	66,223	114,940	54,935	
Model 1 ^a	1.00	0.87 (0.85, 0.90)	0.68 (0.66, 0.71)	0.55 (0.53, 0.57)	<0.001
Model 2 ^c	1.00	0.79 (0.76, 0.81)	0.61 (0.59, 0.63)	0.50 (0.48, 0.52)	<0.001

2 ^a Unadjusted OR (95%CI).3 ^b OR was adjusted for age, sex, ethnicity, educational level, marital status, history of diabetes,
4 family history of hypertension, and self-reported using antihypertensive drugs.5 ^c OR was adjusted for age, sex, ethnicity, educational level, marital status, history of diabetes,
6 and family history of hypertension.

7

Table 4 (on next page)

Table 4 Association between healthy lifestyle score and hypertension control stratified by antihypertensive drugs use

1 Table 4 Association between healthy lifestyle score and hypertension control stratified by
 2 treatment status of hypertension

Healthy lifestyle score		Treatment status of hypertension	
		Treated	Untreated
0-2	OR (95%CI)	1.00	1.00
3	OR (95%CI)	0.79 (0.76, 0.81)	0.65 (0.61, 0.70)
	P^a	<0.001	
4	OR (95%CI)	0.61 (0.59, 0.63)	0.49 (0.46, 0.52)
	P^a	<0.001	
5	OR (95%CI)	0.50 (0.48, 0.52)	0.41 (0.38, 0.44)
	P^a	<0.001	
	$P_{\text{interaction}}$	<0.001	

3 OR was adjusted for age, sex, ethnicity, educational level, marital status, history of diabetes, and
 4 family history of hypertension.

5 ^a P value for difference between the treated group and the untreated group, is given by 2-

6 sample z-test: $z = (\beta_1 - \beta_2) / \sqrt{(SE_1)^2 + (SE_2)^2}$, where β_1 and β_2 indicate the estimates for each

7 subgroup, and SE_1 and SE_2 represent their respective standard errors.

8
