Background. To evaluate the efficacy and safety of Brolucizumab for neovascular age-related macular degeneration (n-AMD) by systematic review and meta-analysis.

Materials and Methods. A comprehensive electronic search was conducted in Cochrane, PubMed, Embase, and Web of Science databases for relevant studies. Stata and RevMan5.4 were used for meta-analysis and bias risk assessment, respectively. Data on the best-corrected visual acuity (BCVA), central subfield thickness (CSFT), presence of intraretinal (IRF) and/or subretinal fluid (SRF), participants with ≥ 1 serious adverse events, and participants with ≥ 1 adverse events were analyzed.

Results. Six studies were included. According to the meta-analysis, there were statistical differences in BCVA [SMD=-0.65, 95%CI (-0.17, -0.23)], the presence of intraretinal (IRF) and/or subretinal fluid (SRF) [RR=0.67, 95%CI (0.56, 0.79)] and the safety of participants with ≥ 1 serious adverse events [RR=0.57, 95%CI (0.39, 0.84)] between the experimental group and the control group. However, no statistical differences were observed in CSFT [SMD=-1.16, 95%CI (-2.79, 0.47)] or the safety of participants with ≥ 1 adverse events [RR=1.07, 95%CI (0.97, 1.17)].

Conclusions. Compared to other anti-VEGF drugs such as Aflibercept and Ranibizumab, intravitreal injection of 6mg Brolucizumab for neovascular AMD is more effective and safe in the treatment of n-AMD, especially in the presence of IRF and/or SRF, and on participants with ≥ 1 serious adverse events.

The efficacy and safety of Brolucizumab for neovascular age-related macular degeneration (AMD): A Systematic Review and Meta-analysis

Abstract

Background. To evaluate the efficacy and safety of Brolucizumab for neovascular age-related macular degeneration (n-AMD) by systematic review and meta-analysis.

Materials and Methods. A comprehensive electronic search was conducted in Cochrane, PubMed, Embase, and Web of Science databases for relevant studies. Stata and RevMan5.4 were used for meta-analysis and bias risk assessment, respectively. Data on the best-corrected visual acuity (BCVA), central subfield thickness (CSFT), presence of intraretinal (IRF) and/or subretinal fluid (SRF), participants with ≥ 1 serious adverse events, and participants with ≥ 1 adverse events were analyzed.

Results. Six studies were included. According to the meta-analysis, there were statistical

differences in BCVA [SMD=-0.65, 95%CI (-0.17, -0.23)], the presence of intraretinal (IRF) and/or subretinal fluid (SRF) [RR=0.67, 95%CI (0.56, 0.79)] and the safety of participants with ≥ 1 serious adverse events [RR=0.57, 95%CI (0.39, 0.84)] between the experimental group and the control group. However, no statistical differences were observed in CSFT [SMD=-1.16, 95%CI (-2.79, 0.47)] or the safety of participants with ≥ 1 adverse events [RR=1.07, 95%CI (0.97, 1.17)].

Conclusions. Compared to other anti-VEGF drugs such as Aflibercept and Ranibizumab, intravitreal injection of 6mg Brolucizumab for neovascular AMD is more effective and safe in the treatment of n-AMD, especially in the presence of IRF and/or SRF, and on participants with ≥ 1 serious adverse events.

Keywords: AMD; anti-VEGF; Brolucizumab; Meta-analysis; Aflibercept; Ranibizumab

Introduction

As we all know, neovascular age-related macular degeneration (n-AMD) is one of the most common causes of blindness (1-3). Current treatment guidelines suggest intravitreal injection of anti-vascular endothelial growth factor (VEGF) agents has become the first-line therapy for n-AMD over the last decade (4, 5). Currently, main agents includes ranibizumab (Lucentis; Genentech, South San Francisco, CA, USA) (6, 7) and aflibercept (Eylea; Regeneron, Tarrytown, NY, USA, and Bayer HealthCare, Berlin, Germany) (8). It is reported that anti-VEGF drugs, such as Aflibercept and Ranibizumab, are effective and safe in the treatment of n-AMD (3, 9-11). Based on safety and efficacy studies of the intravitreal injection of anti-VEGF drugs, Brolucizumab as a new anti-VEGF drug bring us a brand new page on treating n-AMD. Brolucizumab is a humanized single-chain antibody fragment that consists of the tips of the Fab

region of the antibody, linked by a peptide linker. Alike ranibizumab, brolucizumab inhibits all isoforms of VEGF-A. Therefore, we conducted this meta-analysis to analyze the differences in the efficacy and safety between this new drug, Brolucizumab, and other anti-VEGF drugs, in the treatment of n-AMD (12-18).

Furthermore, exploring the efficacy and safety of Brolucizumab (1, 19), which is a new monoclonal antibody anti-VEGF drug for the treatment of n-AMD, is even more meaningful than other anti-VEGF drugs (1, 4, 12, 19).

Although several reticular meta-analyses have been conducted to compare the efficacy of Brolucizumab with other anti-VEGF drugs, no meta-analysis has been published regarding the safety and efficacy of this monoclonal antibody (20, 21). Hence, we conducted this meta-analysis to analyze the safety and efficacy of Brolucizumab in the treatment of n-AMD, so as to provide a reference for the clinical treatment of this condition.

Materials and Methods

This meta-analysis was registered with the International Prospective Register of Systematic Reviews (PROSPERO) (CRD42023389716).

Literature search

Relevant studies were retrieved from foreign databases, including Cochrane, PubMed, Embase, and Web of Science. According to the “PICO” retrieval strategy, the English search words, “Brolucizumab” and “Macular Degeneration”, were used. All studies were retrieved with a combination of subject headings and free words, and the reference lists of the included studies were also manually searched to avoid missing eligible studies. The search strategy (performed by Ran Dou and Jian Jiang who served as screeners) is described in Table S1. And Dongchang Zhang

took place of referee. However, there were no disagreements between the screeners.

Inclusion and exclusion criteria

Inclusion criteria

- 1) Patients: patients were diagnosed with n-AMD;
- 2) Intervention: the experimental groups were treated with the intravitreal Brolucizumab;
- 3) Comparison: the control groups were treated with the intravitreal injection of other anti-VEGF drugs, including Aflibercept or Ranibizumab, which are recognized as effective drugs for AMD.
- 4) Outcomes: the primary outcome measures included best-corrected visual acuity (BCVA) and central subfield thickness (CSFT), while the secondary outcomes were the presence of IRF and/or SRF, presence of sub-RPE fluid, participants with ≥ 1 serious adverse events, and participants with ≥ 1 adverse events.
- 5) Study type: randomized controlled trials (RCTs).

Exclusion criteria

- 1) Animal experiments, meta-analyses, meeting abstracts, letters, or systematic reviews;
- 2) Duplicate literature or suspected plagiarism;
- 3) The original passages were unobtainable;
- 4) Data of interest were unobtainable;
- 5) Non-English literature.

Data Extraction

Two researchers (Ran Dou and Jian Jiang) independently screened the literature according to the inclusion and exclusion criteria. Then they extracted relevant data and cross-checked their results. Extracted data included basic information about the selected studies (e. g., title, first author, journal publication time, region), intervention measures of the control group and the experimental group,

major elements of the risk of bias assessment, and outcome measures of interest.

Quality evaluation

According to the Risk of Bias Assessment tool of Cochrane Collaboration, two investigators (Ran Dou and Jian Jiang) assessed the risk of bias in the included studies. The assessment includes 7 items: random allocation method, allocation scheme hiding, blinding of the research objects and personnel, blinding of the outcome measures, integrity of the outcome data, selective reporting, and other bias. Each item can be evaluated as "low risk," "high risk," or "unclear."

Statistical Analysis

The STATA software was used for the meta-analysis, and the RevMan software provided by the Cochrane Collaboration was used for bias assessment.

Because the doses used in the experimental groups were different, subgroup analysis was performed according to 6mg Brolucizumab and <6mg Brolucizumab. In this meta-analysis, standardized mean difference (SMD) and relative risk (RR) was used as the effect sizes, and a 95% confidence interval (CI) was provided for each effect size. Q-test was used for qualitative analysis, and the I^2 statistic was used to quantify the heterogeneity. When $P > 0.1$ and $I^2 \leq 50\%$, the homogeneity among the studies was considered, and a fixed-effects model was used for meta-analysis. If $P \leq 0.1$, $I^2 > 50\%$, and no clinical heterogeneity was determined, a random-effects model was used for meta-analysis. If clinical heterogeneity was found, subgroup analysis or sensitivity analysis was used to explore the source of heterogeneity.

Results

Literature search process and results

According to the retrieval strategy, a total of 511 studies were obtained. After the duplicates were

removed, 322 studies remained. After reading the titles and abstracts, 290 ineligible articles were excluded. Based on a full-text-review, 6 studies were included. The basic characteristics of the included studies are shown in Figure 1.

Basic characteristics table of the included literature

The 6 included studies (12-17) were all RCTs. The intervention for the experimental group was intravitreal injection of Brolucizumab, while the intervention for the control group was intravitreal injection of other anti-VEGF drugs, such as Aflibercept and Ranibizumab. (show in Table 1)

Offset risk assessment chart

All 6 included studies (12-17) were randomized, double-masked, multicentre clinical trials. All the included studies mentioned the allocation concealment, the blinding of the researchers and subjects, as well as the blinding of the evaluators (Figure 2, Figure 3).

Meta-analysis results

BCVA

As shown in the forest plot, the prismatic figure of indicator fell to the left of the invalid line and did not intersect with the invalid line in the Brolucizumab group. The results showed that the intravitreal injection of Brolucizumab had a worse effect on BCVA than the control [SMD=-0.65, 95%CI (-0.17, -0.23)], and the difference was statistically significant. (show in Figure 4)

As shown in the forest plot for subgroup analysis, the prismatic figure of the indicator fell to the left of the invalid line and intersected with the invalid line in the experimental subgroup treated with 6mg of Brolucizumab. The results showed that no significant difference was present between the subgroup of 6mg Brolucizumab and the control group [SMD=-0.50, 95%CI (-1.19, -0.20)]. In the experimental subgroup treated with <6mg of Brolucizumab, the prismatic figure of the indicator fell to the right of the invalid line and did not intersect with the invalid line. The results

showed that there were differences between the experimental subgroup of <6mg Brolucizumab and the control group [SMD=-0.99, 95%CI (-1.14, -0.84)].

Sensitivity analysis was performed. The results showed that the data were distributed within the interval, indicating that the analysis results were stable.

CSFT

As shown in the forest plot, the prismatic figure of the indicator intersected with the invalid line in the experimental group. The results showed that there was no statistical difference between the experimental group and the control group [SMD=-1.16, 95%CI (-2.79, 0.47)]. (show in Figure 5)

As shown in the forest plot for subgroup analysis, in the experimental subgroups treated with both 6mg Brolucizumab and <6mg Brolucizumab, the prismatic figure of the indicator intersected with the invalid line. The results showed that there was no statistical difference between the experimental subgroup and the control group [6mg Brolucizumab: SMD=-2.52, 95%CI (-6.05, 1.00); <6mg Brolucizumab: SMD=-0.38, 95%CI (-1.98, 1.23)].

Sensitivity analysis was performed. The results showed that the data were distributed within the interval, indicating that the analysis results were stable.

Presence of IRF and/or SRF (F3)

As shown in the forest plot, in the experimental group, the prismatic figure of the indicator fell to the left of the invalid line and did not intersect with the invalid line. The results showed that there were statistical differences between the experimental group and the control group [RR=0.67, 95%CI (0.56, 0.79)].

Sensitivity analysis was performed. The results showed that the data were distributed within the interval, indicating that the analysis results were stable. (show in Figure 6)

Participants with ≥ 1 serious adverse events (F5)

As shown in the forest plot, in the experimental group, the prismatic figure of the indicator intersected with the invalid line. The results showed that there were statistical differences between the experimental group and the control group [RR=0.57, 95%CI (0.39, 0.84)].

As shown in the forest plot for subgroup analysis, in the experimental subgroup treated with 6mg of Brolucizumab, the prismatic figure of the indicator fell to the left of the invalid line and did not intersect with the invalid line. The results showed that there were statistical differences between the experimental group of 6mg Brolucizumab and the control group [RR=0.51, 95%CI (0.28, 0.92)]. In the subgroup treated with <6mg of Brolucizumab, the prismatic figure of the indicator fell to the left of the invalid line and intersected with the invalid line. The results showed that no statistical differences were observed between the experimental group of <6mg Brolucizumab and the control group [RR=0.72, 95%CI (0.53, 0.97)].

Sensitivity analysis was performed. The results showed that the data were distributed within the interval, indicating that the analysis results were stable. (show in Figure 7)

Participants with ≥ 1 adverse events (F6)

As shown in the forest plot, in the experimental group, the prismatic figure of the indicator fell to the right of the invalid line and intersected with the invalid line. The results showed that there was no statistical difference between the experimental group and the control group [RR=1.07, 95%CI (0.97, 1.17)].

As shown in the forest plot for subgroup analysis, in the experimental subgroup, the prismatic figure of the indicator fell to the right of the invalid line, and intersected with the invalid line. The results showed that there was no statistical difference between the experimental subgroup and the

control group [6mg Brolucizumab: RR=1.06, 95%CI (0.91, 1.23); <6mg Brolucizumab: RR=1.07, 95%CI (0.95, 1.26)].

Sensitivity analysis was performed. The results showed that the data were distributed within the interval, indicating that the analysis results were stable. (show in Figure S1)

Evaluation of Publication Bias

The outcome measures of this study were BCVA, CSFT, presence of IRF and/or SRF, participants with ≥ 1 serious adverse events, and participants with ≥ 1 adverse events. Therefore, funnel plots were drawn for the outcome measures. It was visually observed that the scattered distribution on both sides of the funnel plots was asymmetric, indicating the presence of publication bias. (show in Figure S2)

Discussion

In this study, meta-analysis was used to evaluate the effects and safety of different anti-VEGF drugs on n-AMD. 6 studies (21-26) were included and evaluated the efficacy and safety based on BCVA, CSFT, presence of IRF and/or SRF, participants with ≥ 1 serious adverse events, and participants with ≥ 1 adverse events (4, 27, 28). Subgroup analysis was performed according to different doses of Brolucizumab.

Safety of Brolucizumab is the primary consideration in clinical medication. Three studies (21, 24, 25) reported the safety of participants with ≥ 1 adverse events, and the meta-analysis showed that there was no statistical difference between the experimental group and the control group. This indicates that intravitreal injection of Brolucizumab is as safe as other anti-VEGF drugs in participants with ≥ 1 adverse events. In addition, the meta-analysis results of five studies (23-26, 29) showed that intravitreal injection of 6mg Brolucizumab ended in better results regarding the

safety (30) of participants with ≥ 1 serious adverse events. That is to say, brolucizumab is as safe as other anti-VEGF drugs for n-AMD, especially for those with serious adverse events, which provides us with a safe guarantee for clinical application.

On the premise that safety is not inferior to other anti-VEGF drugs, effectiveness analysis has become the most important indicator of clinical medication. It is well known that BCVA, CSFT and presence of IRF and/or SRF are the basis for judging whether Brolucizumab is effective or not in the treatment of n-AMD. The meta-analysis results of three studies (22, 25, 26) reported on BCVA showed that the intravitreal injection of 6mg Brolucizumab had the same efficacy as the control, although other concentrations used in the experimental groups showed a poorer effect. Therefore, in order to obtain the same BCVA as aflibercept, Brolucizumab at a dose of 6mg should be administered. As regards CSFT, the meta-analysis results showed that Brolucizumab did not have superiority (31, 32). Brolucizumab did not outperform the control agents in CSFT. Then if a concentration of $>6\text{mg}$ Brolucizumab was used, could it be better on the BCVA and CSFT Under the premise of non-inferior safety to other anti-VEGF drugs? Which dose would be the best? This may be explored further in the future.

The meta-analysis results showed that intravitreal injection of Brolucizumab had a better effect than aflibercept on the presence of IRF and/or SRF. In treatment cases, we found that the Brolucizumab group showed better results than the control group on morphology. Furthermore, about the molecule characteristics, just like ranibizumab, Brolucizumab inhibits VEGF-A alone. However, because of its low molecular weight and high stability and solubility, it can be highly concentrated and administered in molar doses 12 times higher than that of aflibercept, and 22 times higher than that of ranibizumab (19). The anatomical impact of such high-dose administration of Brolucizumab on the choroid might result in a more successful resolution of SRF and IRF.

Combined with the above-mentioned effects on BCVA and CSFT, although the drug is able to be accumulated in high concentrations, it did not show superiority in reducing CSFT, despite its excellent morphological performance. In brief, if brolucizumab could play a better role in CSFT, it may have a more impressive curative effect.

In the global phase III HAWK and HARRIER trials, intravitreal injections of Brolucizumab every 3 months after the loading phase yielded visual outcomes similar to those of intravitreal aflibercept injections administered every 2 months (19), which is a more convenient and cheaper choice for the patients with n-AMD. Brolucizumab might bring much better therapeutic effects for clinical treatments. However, the evaluation indicators of the included studies were different, and the sample sizes of the same outcome indicators were limited. Therefore, the results of this meta-analysis should be interpreted carefully. Also, the scope of this study was limited to English papers, and some high-quality studies reported in other languages may be ignored. More large-sample, multicenter, and high-quality clinical studies are needed to demonstrate the efficacy and safety of Brolucizumab.

Conclusions

Compared to other anti-VEGF drugs such as Aflibercept and Ranibizumab, intravitreal injection of 6mg Brolucizumab for neovascular AMD is more effective and safe in the treatment of n-AMD, especially in the presence of IRF and/or SRF, and on participants with ≥ 1 serious adverse events.
