

Heterobranch sea slugs (Gastropoda: Heterobranchia) from the Región de Atacama, northern Chile, with the description of a new species of *Berthella* Blainville, 1825

Juan Francisco Araya, Ángel Valdés

The coasts of the Región de Atacama, in northern Chile, have been sparsely studied in regard to its invertebrate fauna, with just a few works reviewing the distribution of their local mollusks. This work reviews the littoral communities of heterobranch sea slugs currently occurring around the port of Caldera (27° S), in the Región de Atacama, northern Chile. Nine species of sea slugs were found in this study: *Baptodoris peruviana* (d'Orbigny, 1837), *Diaulula punctuolata* (d'Orbigny, 1837), *Doris fontainei* (d'Orbigny, 1837), *Ercolania evelinae* (Marcus, 1959), *Onchidella marginata* (Couthouy in Gould, 1852), *Peltodoris marmorata* (Bergh, 1898), *Phidiana lottini* (Lesson, 1831), *Tyrinna nobilis* Bergh, 1898 and the new species *Berthella schroedli* sp. nov., described herein. All of the species found in the area are endemic to South America, having distributions in the southeastern Pacific and south Atlantic Oceans, from Ancash, Perú to Peninsula Valdés, Argentina; two species are endemic to the Chilean coasts (*Berthella schroedli* and *Peltodoris marmorata*), and three species, *Diaulula punctuolata*, *Ercolania evelinae* and *Phidiana lottini*, constitute new distribution records in the area. Further surveys, particularly in subtidal and deeper waters, are essential to improve the knowledge on this neglected fauna.

ABSTRACT

The coasts of the Región de Atacama, in northern Chile, have been sparsely studied in regard to its invertebrate fauna, with just a few works reviewing the distribution of their local molluscs. This work reviews the littoral communities of heterobranch sea slugs currently occurring around the port of Caldera (27° S), in the Región de Atacama, northern Chile. Nine species of sea slugs were found in this study: *Baptodoris peruviana* (d'Orbigny, 1837), *Diaulula punctuolata* (d'Orbigny, 1837), *Doris fontainei* (d'Orbigny, 1837), *Ercolania evelinae* (Marcus, 1959), *Onchidella marginata* (Couthouy in Gould, 1852), *Peltodoris marmorata* (Bergh, 1898), *Phidiana lottini* (Lesson, 1831), *Tyrinna nobilis* Bergh, 1898 and the new species *Berthella schroedli* sp. nov., described herein. All of the species found in the area are endemic to South America, having distributions in the southeastern Pacific and south Atlantic Oceans, from Ancash, Perú to Peninsula Valdés, Argentina; two species are endemic to the Chilean coasts (*Berthella schroedli* and *Peltodoris marmorata*), and three species, *Diaulula punctuolata*, *Ercolania evelinae* and *Phidiana lottini*, constitute new distribution records in the area. Further surveys, particularly in subtidal and deeper waters, are essential to improve the knowledge on this neglected fauna.

INTRODUCTION

The mollusks of the Región de Atacama, in northern Chile, have been sparsely studied; most of the species commonly present in the area were described in the nineteenth century

(Broderip & Sowerby, 1832; Sowerby, 1832, 1833; d'Orbigny, 1835-1847; Gould, 1852; Hupé in Gay, 1854, among others), with a few works reviewing species during the past century (Dall, 1909; Gigoux, 1932, 1934; Rehder, 1945) and, more recently, with several works describing new species (Osorio, 2012; Araya, 2013; Miquel & Araya, 2013; Araya, 2015a, 2015b; Collado, 2015) or giving new records for them (Araya & Araya, 2015). Regarding Heterobranch sea slugs in particular, only the studies by Marcus (1959), Schrödl (1996a, 1996b, 1997, 2003) and most recently Labrín, Guzmán & Sielfeld (2015) have included species from the northern Chile. However, a few recent papers dealing with the Peruvian fauna, including some species commonly found in Chilean waters (e.g., Millen *et al.* 1994; Nakamura 2006, Martynov & Schrödl 2011; Uribe *et al.* 2013; Schrödl & Hooker, 2014 and others), have also contributed to the knowledge of this group in the southeastern Pacific.

The present study provides records of sea slugs found in shallow waters around Caldera (27° S), Region of Atacama, northern Chile. The coast of this area consists of rocky formations with sparse sandy beaches and a comparatively narrow intertidal zone. Rocky platforms, boulder fields and intertidal pools are common; however some sheltered areas have open sandy beaches, usually exposed to strong surf. The sea slug fauna recorded in the area in this study consisted of nine species, including *Baptodoris peruviana* (d'Orbigny, 1837), *Diaulula punctuolata* (d'Orbigny, 1837), *Doris fontainei* (d'Orbigny, 1837), *Ercolania evelinae* (Marcus, 1959), *Onchidella marginata* (Couthouy in Gould, 1852), *Peltodoris marmorata* (Bergh, 1898), *Phidiana lottini* (Lesson, 1831), *Tyrinna nobilis* Bergh, 1898 and *Berthella schroedli* sp. nov., a new pleurobranchomorph species described herein. All of these species are endemic to southern South America; with three of them presenting new distributional records in Chile. The aim of this preliminary study is to contribute additional information to the knowledge of the molluscan fauna in Chile, particularly from the largely neglected northern coasts.

MATERIALS AND METHODS

The material examined was collected in the summers of 2010, 2011 and 2012 in diverse locations near the port of Caldera (27° S), Region of Atacama, northern Chile. All the collecting was made manually in the intertidal areas, mostly on rocky outcrops and tidal pools. The specimens were deposited in the collections of the Museo de Paleontología de Caldera (MPCCL), Caldera; Museo de Zoología de la Universidad de Concepción (MZUC), Concepción,

Chile, and in the collection of the Natural History Museum of Los Angeles County Museum (LACM), Los Angeles, California, USA. Field study permits were not required for this study and none of the species studied herein are currently under legal protection. All the collected specimens were preserved in 95 % ethanol. Photographs of living animals were taken with a Canon A530 digital camera and a 10x geologic loupe. All sizes given are living measurements, radular features were examined by scanning electron microscopy (SEM). Color plates were composed with basic image programs and colors of the images were not modified. The electronic version of this article in Portable Document Format (PDF) will represent a published work according to the International Commission on Zoological Nomenclature (ICZN), and hence the new names contained in the electronic version are effectively published under that Code from the electronic edition alone. This published work and the nomenclatural acts it contains have been registered in ZooBank, the online registration system for the ICZN. The ZooBank LSIDs (Life Science Identifiers) can be resolved and the associated information viewed through any standard web browser by appending the LSID to the prefix <http://zoobank.org/>. The LSID for this publication is: urn:lsid:zoobank.org:pub:088D994A-9E1E-4324-A6DF-FCCC2B0E3437. The online version of this work is archived and available from the following digital repositories: PeerJ, PubMed Central and CLOCKSS.

RESULTS

Systematic Account

Heterobranchia

Infraclass Opisthobranchia

Order Nudibranchia Cuvier, 1817

Superfamily Aeolidioidea Gray, 1827

Family Facelinidae Bergh, 1889

Genus *Phidiana* Gray, 1850

Type species *Eolidea patagonica* d'Orbigny, 1836, by subsequent designation by Alder & Hancock (1855).

Phidiana lottini (Lesson, 1831)

(Fig. 1A)

123 *Eolidia lottini* Lesson, 1831: 290, pl. 14, fig. 6.
 124 *Cavolina lottini* (Lesson): d'Orbigny, 1837: 194.
 125 *Phidiana lottini* (Lesson): Schrödl 1996a: 41, pl. II, fig. 13. pl. VII, fig. 41; Schrödl 2003: 83,
 126 figs. 51, 63, 64, 88; Schrödl *et al.* 2005: 7, pl. 2, fig. 17; Uribe *et al.* 2013: 52, fig. 3. Schrödl &
 127 Hooker 2014: 54, figs. 12, 13.
 128 *Phidiana inca* (d'Orbigny, 1837): Gray, 1850: 108; Bergh, 1867: 100, pl. 3, figs. 1–13. Marcus,
 129 1959: 79, figs. 184–190; Álamo & Valdivieso, 1997: 85.
 130 A detailed chresonymy can be found in Schrödl (2003).
 131 **Material examined:** Two specimens (MZUC XXXX); in a tidal pool in a rocky outcrop, Playa
 132 Brava (27°03' S; 70°49' W), Caldera, Región de Atacama, Chile and one specimen (MZUC
 133 XXXX); collected inside empty *Austromegabalanus psittacus* (Molina, 1782) shells in Calderilla
 134 (27°05' S; 70°50' W), Caldera, Región de Atacama, Chile (MPCCL XXXX).
 135 **Description:** Elongate body of white to sometimes reddish color, covered by 20-26 parallel rows
 136 of conspicuous cerata. Dorsum with a white line. Cerata orange-brown and white in colour.
 137 Rhinophores annulate, whitish. Oral tentacles long and pinkish-white. Anterior foot corners
 138 slightly extended.
 139 **Distribution:** *Phidiana lottini* has been recorded in Chile from Los Hornos (29°38' S; 71°20' W)
 140 to the Guaitecas Islands (44° S), southern Chile (Schrödl & Hooker 2014). This species has also
 141 been recorded from Ancash, Isla Santa, Lima, and Callao, central Peru (12°02' S) (Uribe *et al.*
 142 2013; Schrödl & Hooker, 2014). This is the northernmost record for the species in Chile.
 143 **Remarks:** *Phidiana lottini* is easily recognizable from other aeolid sea slugs because of the
 144 cerata arranged in parallel rows and the presence of a white dorsal line between the rhinophores.
 145
 146 **Superfamily Doridoidea**
 147 **Family Chromodorididae Bergh, 1891**
 148 **Genus *Tyrinna* Bergh, 1898**
 149 **Type species** *Tyrinna nobilis* Bergh, 1898, by monotypy.
 150
 151 ***Tyrinna delicata* Abraham, 1877**
 152 **(Fig. 1B)**
 153 *Doris delicata* (Abraham, 1877): 211, pl. XXX, figs. 20-22.

Tyrinna nobilis Bergh, 1898: 523, pl. 30, figs. 21–29, pl. 32, figs. 21–24; Marcus, 1959: 31, figs. 45–53; Muniaín, Valdés & Ortea, 1996: 265, figs. 2–6; Schrödl 1996a: 22, pl. 3, fig. 15; 1997: 41; Schrödl 2003: 31, figs. 15, 70; Schrödl *et al.* 2005: 4, pl. 1, fig. 8; Schrödl & Millen 2001: 1146, figs. 1–6; Uribe *et al.* 2013: 48, fig. 2A.

Tyrinna pusae Marcus, 1959: 33, figs. 54–64.

A detailed chresonymy can be found in Schrödl (2003: 31)

Material examined: One specimen (MZUC XXXX); under rocks at low tide, in tidal pools in rocky outcrops, North of Obispito (26°45'51" S; 70°45'07" W), Caldera, Región de Atacama, Chile.

Description: Body oval-elongate, translucent-whitish, with opaque white lines surrounding the edges of foot and mantle. Dorsum smooth, lacking tubercles, with irregular and submarginal rows of orange spots, absent from the central region of mantle. Oral tentacles longitudinally enrolled. Anterior part of foot bilabiate, forming a thick lip. Posterior end of the foot extending beyond the mantle in crawling individuals (After Uribe *et al.* 2013).

Distribution: From Valdés Peninsula, in the Atlantic Magellan Strait, to Los Piqueros Beach (26°12' S; 70°39' W), Chañaral (Schrödl & Millen 2001). This species has been also recorded in the Juan Fernández Islands, Chile and in Perú at San Juan de Marcona, Ica and Isla Blanca, Arequipa (Uribe *et al.* 2013).

Remarks: This species is clearly distinguishable from other nudibranchs in the dorsal row of orange spots, which are very visible in the mantle.

Family Discodorididae Bergh, 1891

Genus *Baptodoris* Bergh, 1884

Type species *Baptodoris cinnabarina* Bergh, 1884, by monotypy.

Baptodoris peruviana (d'Orbigny, 1837)

(Fig. 1C)

Doris peruviana d'Orbigny, 1837: 188, pl. XV, figs. 7–9.

Doriopsis peruviana Dall, 1909: 203.

Platydorid punctatella Bergh, 1898: 521, figs 12–20; Dall, 1909: 203; Schrödl, 1996a: 23, pl. IV, fig. 27.

185 *Dendrodoris peruviana* (d'Orbigny, 1837): Álamo & Valdivieso, 1997: 85.

186 *Platydoris peruviana* (d'Orbigny, 1837): Schrödl, 2003: 34, figs. 17, 54, 71.

187 *Baptodoris peruviana* Fischer & Cervera, 2005a: 515, figs. 1–8.

188 *Baptodoris? peruviana* Schrödl & Hooker, 2014: 48, fig. 4.

189 **Material examined:** One specimen (MZUC XXXX); under rocks at very low tide, Playa

190 Ramada (27°00' S; 70°48' W) Caldera, Región de Atacama, northern Chile.

191 **Description:** Elevated, oval and slightly convex white-yellowish body, with minute brown spots
192 over the notum which is densely covered by very small rounded caryophyllidia. Rhinophores and
193 gills hyaline white, not elevated. Rhinophores are perfoliate with 7–10 lamellae. The branchial
194 tuft consists of 6 uni-bipinnate gills, which form a circle around the anus at the posterior end of
195 the body. Ventrally, the head is small with short digitiform oral tentacles. The foot is narrow,
196 with the anterior edge notched at the mid-line and grooved. The notal margin is white and wider
197 than the foot (After Fischer & Cervera, 2005a).

198 **Distribution:** According to Fischer & Cervera (2005a), this species has been recorded from
199 South of San Lorenzo Island, Lima, Peru to Valparaiso, (33°02' S; 71°38' W) Chile.

200 **Remarks:** The subtle granulose texture of the notum produced by the presence of very small
201 rounded caryophyllidia and their inconspicuous appearance is useful to difference this species
202 from all other sea slugs found in the area.

203

204 **Genus *Diaulula* Bergh, 1884**

205 **Type species** *Doris sandiegensis* (Cooper, 1863), by monotypy.

206

207 ***Diaulula punctuolata* (d'Orbigny, 1837)**

208 (Fig. 1D)

209 *Doris punctuolata* d'Orbigny, 1837: 187, pl- 16, figs. 4–6.

210 *Diaulula punctuolata* (d'Orbigny, 1837): Valdés & Gosliner 2001: 136, figs. 22, 23; Schrödl
211 2003: 39, figs. 20, 56, 74; Fischer & Cervera 2005b: 173. Detailed bibliography and synonymy
212 can be found in Schrödl (2003: 39)

213 **Material examined:** One specimen (MZUC XXXX); under rocks at very low tide, North of
214 Obispito (26°45' S; 70°45' W), 40 km N of Caldera, Región de Atacama, Chile.

Description: Whitish-yellowish body with minute black spots over the notum, which is densely covered by small and narrow caryophyllidia. Wide free mantle rim. Rhinophoral and branchial sheaths elevated, covered with caryophyllidia. Six to seven gills, ramified up to four-five times. Oral tentacles long and digitiform. Foot bilabiate, with upper lip notched. Lip cuticle smooth. Rhinophores have more than 15 lamellae (After Schrödl, 2003).

Distribution: According to Fischer & Cervera (2005b), this species has been recorded from Valparaíso, Chile (33°02' S; 71°38' W) to the Argentinian Patagonia. This is the northernmost record for the species in Chile.

Remarks: The velvety texture of the dorsum produced by the presence of caryophyllidia is useful to difference this species from similar sea slugs.

Genus *Peltodoris* Bergh, 1880

Type species *Peltodoris atromaculata* Bergh, 1880, by subsequent designation by O'Donoghue (1926)

***Peltodoris marmorata* (Bergh, 1898)**

(Fig. 1E)

Anisodoris marmorata Bergh, 1898: 515, pl. 30, figs. 5–7 (non *Archidoris marmorata* Bergh, 1881). Marcus, 1959: 45, figs. 98–103.

Anisodoris rudberghi Marcus & Marcus, 1967: 69; Schrödl, 1996: 25, pl. IV, figs. 21–22.

Peltodoris marmorata (Bergh, 1898): Valdés & Muniaín, 2002: 349, figs. 1D, 4, 5.

Diaulula variolata (D'Orbigny, 1837): Schrödl, 2003: 41, figs. 21, 57, 75.

Material examined: Two specimens (MZUC XXXX); under rocks in very low tide, Calderilla (27°05' S; 70°50' W), S of Caldera, Región de Atacama, Chile.

Description: Brownish-white body, a plain brownish mantle covered by very small rounded tubercles of different sizes. Six to eight tri- to quadripinnate gills. Oral tentacles long and digitiform. Foot bilabiate, with a notched anterior edge. Lip cuticle smooth (After Schrödl, 2003)

Distribution: This species has records in Chile from Arica (18° S) Schrödl (2003) to Bernardo O'Higgins Park (51° S), Aysén (Aldea, Céspedes & Rosenfeld, 2011). This species was rare in the area and it was found only in two places, under rocks in the lower intertidal zone.

Remarks: This is a very inconspicuous sea slug, some uncollected specimens were found under large rocks among encrusting algae and bryozoans; they can be easily identified, however, by the notched anterior edge and the plain, dark mantle. This species has a complex taxonomic history and it is also regarded as a synonym of *Diaulula variolata* (d'Orbigny, 1837).

Family Dorididae Rafinesque, 1815

Genus *Doris* Linnaeus, 1758

Type species *Doris verrucosa* Linnaeus, 1758, by monotypy.

***Doris fontainii* d'Orbigny, 1837**

Doris fontainii d'Orbigny, 1837: 189, pl. 15, figs. 1–3.

Anisodoris fontaini (d'Orbigny, 1837): Odhner, 1926: 85, figs. 70–72, pl. 3, figs. 47–49; Schrödl, 1996a: 24, pl. III, fig. 19. Schrödl, 2000b: 73, fig. 2–3.

Doris fontainei (d'Orbigny, 1837): Gay, 1854: 76; Valdés & Muniaín, 2002: 346, figs. 1A–B, 2A–C, 3 A–B. Uribe *et al.* 2013: 51, fig. 3E. Schrödl & Hooker, 2014: 47, fig. 2.

Archidoris fontaini (d'Orbigny, 1837): Schrödl, 2003: 45, figs. 24, 58, 76; Schrödl *et al.* 2005: 4, pl. 2, fig. 9; Schrödl & Grau, 2006: 5, fig. 2A–B.

Material examined: Two specimens (MZUC XXXX); in tidal pools at El Jefe Beach (27°03'46" S; 70°49' W), Bahía de Caldera, Región de Atacama, Chile.

Description: Orange to brownish body coloration, with a highly arched body. Notum covered with many small (up to 5 mm in diameter) rounded tubercles. Five to seven tri- to quadripinnate gills. Gills and rhinophores surrounded by elevated sheaths with small tubercles. Oral tentacles triangular, grooved. Foot broad, anteriorly bilabiate and notched. Lip cuticle smooth (After Schrödl, 2003).

Distribution: This species has been recorded from Ancash, Islote Ferrol, Peru (Uribe *et al.* 2013) to northern Argentina (Valdés & Muniaín, 2002).

Remarks: This species is easily recognizable due to its large size, brilliant orange body color and a mantle covered with conspicuous rounded tubercles. Of the examined specimens, none had the dark brown pigment between the tubercles, which Schrödl *et al.* (2005), regarded as characteristic of central and northern Chilean specimens. This was the most common species in the area; they are usually found in the subtidal zone but specimens were also collected from tidal

pools at low tide. According to some commercial divers this species is common below 3 m depth near Bahía Inglesa (27°07' S; 70°52' W), south of Caldera.

Order Pleurobranchomorpha Schmekel, 1985

Superfamily Pleurobranchoidea Gray, 1827

Family Pleurobranchidae Gray, 1827

Genus *Berthella* Blainville, 1824

Type species *Bulla plumula* Montagu, 1803, by original designation.

***Berthella schroedli* sp. nov.**

(Figs. 2A-C, 3A-D, 4, 5C)

Type material: Holotype: 22 mm alive, 18 x 7 mm, preserved in ethanol, Playa El Pulpo (27° 01' 22" S; 70° 48' 30" W), Caldera, Región de Atacama, Chile, intertidal under sunken rocks in rocky coast, 1 m depth, 29 December 2012, coll. & leg. JF Araya, MZUC XXXX. Paratypes 1-3 LACM XXX-XXX, paratypes 4-6 MPCCL XXX-XXX. All the type material is preserved in ethanol 96%.

Diagnosis: *Berthella* with a dark brown-reddish shell decorated with pale radial lines; visible through the translucent yellowish mantle, with an oval and slightly crenulated margin and very small tubercles covering the notum.

Description: Body reaching lengths up to 25 mm in fully extended living specimens (Figs. 2A, 2B, 5A). Body uniformly pale yellowish, translucent; with an internal shell of brownish-reddish color, visible through the mantle. Mantle with a smooth appearance, but with very small tubercles covering the dorsum which gives the animal, at high magnification, a somewhat wrinkled appearance. The mantle processes do not show obvious spicules. Dark and minute eyes located at the base of the rhinophores, hidden beneath the anterior edge of the mantle (Fig. 2B). Notum wide, oval and slightly crenulated, with a broad free margin around. Gill and foot covered by the notum in living specimens, and oral veil and rhinophores partially covered in their posterior part. Mantle lacking an anterior notch. Rhinophores short and stout, joined together at the base. Foot bilabiate anteriorly. Oral veil trapezoidal, protruding from the mantle. Gill located on the right side of the body, lying longitudinally between the mantle and the foot; it is attached

to the body for more than half of its length. Gill bipinnate, with 13 pinnae on either side of the rachis. Rachis smooth, lacking tubercles. Anus located dorsal to the central area of the gill. Egg masses are small white spiral ribbons, up to about 25 mm in diameter (Fig. 4A).

Shell: Shell fully internal, flattened, rectangular/oval in shape, elongate and located centrally in the dorsal area, where it covers completely the viscera. Shell reddish brown in color, somewhat nacreous/iridescent, with radial rays of pale yellowish which are visible through the mantle in living specimens. Margins of shell sharp and fragile. Protoconch of about 300 µm in diameter, smooth under low magnification. Teleoconch with fine concentric ridges crossed by very fine radial striae, the first whorls have a cancellated sculpture (Fig. 2C). **Radula:** Jaws with elongate cruciform elements rather slender, elongate and lanceolate with a narrower base; each element consisting of a central cusp flanked by 2-3 denticles on either side of a prominent central cusp (Fig. 3D). Radular formula: 50 x 45.0.45. Radular teeth hook-shaped lacking denticles (Fig. 3A). Innermost lateral teeth slightly smaller than those from the middle portion of the half row (Fig. 3B). Outermost lateral teeth with a much more elongate cusp than the mid laterals (Fig. 3C). **Reproductive system:** The ampulla is long and muscular, merging proximally into the female gland complex. The penis is wide, with an elongate tip; it connects proximally into a short deferent duct that splits into the prostate and the elongate, muscular penial gland. The prostate is convoluted and connects proximally to the female gland complex. The vagina is elongate, straight; it narrows and connects to the round and large bursa copulatrix. The seminal receptacle is elongate, muscular and about twice as long as the bursa copulatrix; it connects to the vagina before it enters the bursa copulatrix. A uterine duct could not be observed (Fig. 4).

Habitat: This species is found exclusively under rocks sunken at low tide in an almost infaunal habitat; it can be found associated to encrusting sponges, bryozoans, encrusting algae and to communities of micromollusks including *Acar pusilla* (Sowerby, 1833), *Brachidontes granulata* (Hanley, 1843), *Liotia cancellata* Gray, 1848 and *Mitrella unifasciata* (Sowerby, 1832). This particular habitat is also unique for the endemic minute chitons *Callistochiton pulchellus* (Gray, 1828) and *Calloplax vivipara* (Plate, 1899) (Araya & Araya, 2014).

Distribution: This species is somewhat rare but broadly distributed in the area of study; small populations were found only in four localities, in about 40 km of coast, always under rocks (table 1). According to Schrödl (2003) this genus has records in South America from the southernmost Patagonian shelf (Burdwood Bank), south-eastern Atlantic Ocean to southern Chile and north to

Quiriquina Island, central Chile. The genus thus extends its distribution in Chile more than 1100 km to the north.

Etymology: Named in honor of Michael Schrödl (Zoologische Staatssammlung München, München, Germany), for his extensive contributions to the Chilean Opisthobranchia.

Remarks: Of the 16 valid species of *Berthella* known worldwide (Hermosillo & Valdés, 2008), only two have been reported for southern South America: *Berthella patagonica* (d'Orbigny, 1837) and *Berthella platei* (Bergh, 1898). The western Atlantic *Berthella patagonica*, distributed from Central Argentina to Peninsula Valdés, southern Argentina (Schrödl, 2003), differs from the new species in having smaller body dimensions, with a very narrow free mantle rim and a notum apparently lacking a porous texture and not covering completely the foot which, in contrast to the new species, has a quadrangular outline (Schrödl, 1999, 2003). The Magellanic *Berthella platei*, distributed from the Burdwood Bank, southeastern Atlantic Ocean to Quiriquina Island, Central Chile (Schrödl, 1999), differs from the new species in having a more translucent body, of uniform pale pink to pale orange or whitish coloration of living animals (Fig. 5A, 5B), a higher number (15-24) of branchial lamellae versus 11-14 in *B. schroedli* sp. n. and a paler internal shell, translucent brown to greyish in color, in contrast to the reddish-brown shell with faint whitish axial streaks of the new species. The radular formula and the elements of the jaws also differ; *Berthella schroedli* sp. n. have fewer radular rows and less teeth per half row than *B. platei*, and it has also larger elongate and lanceolate elements with a narrower base and thin denticles, while *B. platei* have smaller and more triangular elements with a broader base and slightly broader denticles (see Schrödl, 1999). The shell length in relation to the body size in *B. schroedli* is also comparatively larger than in *B. platei*. In regard to their habitat; the new species has been found almost solely under sunken rocks in relatively shallow water in the intertidal; while *Berthella platei* is found only subtidally, living in the ocean floor usually under 5 m depth (Dirk Schories pers. comm.)

Other Eastern Pacific species of *Berthella* include *Berthella agassizi* (MacFarland, 1909); *Berthella californica* (Dall, 1900); *Berthella grovesi* Hermosillo & Valdés, 2008; *Berthella martensi* (Pilsbry, 1896); *Berthella stellata* (Risso, 1826) and *Berthella strongi* (MacFarland, 1966). All these species differ from *Berthella schroedli* sp. n. chiefly in their external coloration, by having opaque white spots (*B. agassizii*, *B. strongi*) or light brown spots and/or an orange body with dark brown lines and spots (*B. martensi*), a marginal notal band (*B. californica*), dark

spots in the middle of thick opaque white ringlets (*B. grovesi*) or a dorsal streak of white running perpendicularly across the notum, which is translucent white or honey colored (*B. stellata*).

Order Sacoglossa Ihering, 1876

Superfamily Limapontioidea Gray, 1847

Family Limapontiidae Gray, 1847

Genus *Ercolania* Trinchese, 1872

Type species *Ercolania siottii* Trinchese, 1872, by original designation.

***Ercolania evelinae* (Marcus, 1959)**

(Fig. 1F)

Stiliger (*Stiliger*) *evelinae* Marcus, 1959: 22, figs. 28–33. *Ercolania evelinae* Schrödl, 1996a: 44, fig. 2.

Material examined: One specimen photographed alive (not collected); on filamentous algae in tidal pool at very low tide, Playa Brava (27°03' S; 70°49' W), Caldera, Región de Atacama, Chile.

Description: Body minute, up to about 5 mm in examined specimen, with an elongated body, narrowed anteriorly; of brown to deep greenish-black color, with two clear areas at the sides of the head. Two rows of longitudinal cerata in the border of the mantle, with up to six cerata per row (After Schrödl, 1996a).

Distribution: *Ercolania evelinae* has a discontinuous distribution from Paracas (13° S), Peru to the Magallanes Strait (55° S) in Chile (Schrodl & Hooker, 2014). This is the northernmost distribution record of this species in the country.

Remarks: This tiny sacoglosan is one of the smallest and most inconspicuous sea slug in the area.

Order Systellommatophora Pilsbry, 1948

Superfamily Onchidioidea Rafinesque, 1815

Family Onchidiidae Rafinesque, 1815

Genus *Onchidella* J. E. Gray, 1850

Type species *Onchidium nigricans* Quoy & Gaimard, 1832, by subsequent designation by Fischer and Crosse (1878).

***Onchidella marginata* (Couthouy in Gould, 1852)**

Peronia marginata Couthouy in Gould, 1852: 292; atlas, 1856: pl. 22, figs. 386a–c. *Onchidium chilense* Gay, 1854: 120. *Onchidella marginata* Marcus, 1959: 16, fig. 17–20. Dayrat, 2009: 13. Rosenfeld & Aldea, 2010: 35, figs. 1A–B. A more complete synonymy can be found in Dayrat (2009).

Material examined: Twenty specimens (four of them at MZUC XXXX); under small rock slabs at low tide, Playa El Pulpo (27°03' S; 70°49' W), Caldera, Región de Atacama, Chile.

Description: Body elongate ovate, narrowed anteriorly; back very convex, deep greenish-black, very thickly covered with minute tubercles; margin ornamented with alternate bars of black and white; head broad, bilobed in front, and projecting considerably beyond the mantle when the animal is in motion, of a pale yellow color, tinted bluish about the mouth; tentacles rather long, and bulbous at the extremity, pale slate-color, except at the tips, which are black; under side of the mantle pale yellowish, becoming greenish at the margin, where it shows alternate bands of green and pale yellow (After Gould, 1852).

Distribution: *Onchidella marginata* has a discontinuous distribution from Iquique (20° S) to the Magallanes Strait (55° S) in Chile, and to the Isla de los Estados in the South Atlantic of Argentina.

Remarks: This is the only pulmonate sea slug found in Chile (Valdovinos, 1999; Dayrat, 2009); it is usually found in small communities living in under rocks and camouflaging against their surroundings. In the area under study this species share its habitat with other molluscs as the limpet *Lottia orbigny* (Dall, 1909), and the chitons *Chaetopleura peruviana* (Lamarck, 1819) and *Radsia barnesi* (Gray, 1828). This species is easily identifiable from similar intertidal gastropods in the region due to the absence of a shell, the alternating white and green bands in the edge of the mantle and its small size.

DISCUSSION

The present work updates the knowledge on the marine fauna of northern Chile; from the 65 species of sea slugs (only including Nudibranchia and Pleurobranchioidea) recorded to live in

Chilean waters (Schrödl, 2003), nine species were recorded in the Region of Atacama, accounting for about 15 % of the Chilean sea slug fauna. All of the species occurring in the area have widespread ranges in the southeastern Pacific Ocean, from Ancash, Peru to the Strait of Magellan, in southern Chile and in the South Atlantic Ocean, to Peninsula Valdés, in Argentina. With the exception of *Berthella schroedli* sp. n., all of the species found in the Region of Atacama also occur in central and southern Chile. The absence of species previously cited for the area (Schrödl, 1996a, 2003; Schrödl & Hooker, 2014), for example *Corambe lucea* Marcus 1959; *Janolus rebecca* Schrödl, 1996; *Okenia luna* Millen, Schrödl, Vargas & Indacochea, 1994 and *Thecacera darwini* Pruvot-Fol, 1950, among others) could be explained due to the limit of sampling depth, which was restricted to the lower intertidal areas with a maximum of 2 m depth.

Heterobranch sea slugs have been rarely treated in studies reviewing the biodiversity of mollusks from northern Chile in general (e. g. Marincovich, 1973; Guzmán *et al.* 1998), despite the comparatively high number of species recorded in the country. This is in part explained by the current lack of experts working actively in the field and the difficulties involved in collecting and preserving marine slugs. The preservation of specimens usually changes some characteristics of the slugs, mostly their colors. The finding of a new species of *Berthella* in northern Chile also highlights the need of further studies in the area or in northern Chile in general, which have recently revealed new invertebrate species (Reiswig & Araya, 2013; Collado, 2015) or new distributions for obscure or rare species, both from shallow and deeper waters (Araya & Araya, 2015b; Araya & Aliaga, 2015; Araya *et al.* 2015).

ACKNOWLEDGMENTS

We are very grateful to Marta Araya (Caldera, Chile) for her assistance in field collecting, to Carlo Magenta Cunha (Academy of Natural Sciences of Drexel University, Philadelphia, USA), Michael Schrödl (Zoologische Staatssammlung München, München, Germany) and to Cecilia Osorio (Universidad de Chile, Santiago, Chile) for their help with essential bibliography and to Dirk Schories (University of Rostock, Rostock, Germany) for his help with the images and information on *Berthella platei* from southern Chile.
