

## Advertisement call and genetic structure conservatism : good news for an endangered Neotropical frog

Lucas R Forti, William P Costa, Lucas B Martins, Carlos H L Nunes-de-Almeida, Luís Felipe Toledo

**Background.** Many amphibian species are negatively affected by anthropogenic habitat change. Populations distributed over modified landscapes may be subject to local extinction or may be relegated to remaining, likely isolated and possibly degraded, patches of available habitat. Isolation without gene flow can lead to variability in phenotypic traits due to differences in local selective pressures, such as environmental structure, microclimate or site-specific species assemblages.

**Methods.** Here we tested this microevolution hypothesis by evaluating the acoustic parameters of 349 advertisement calls from 15 males representing six populations of the endangered species *Proceratophrys moratoii*. In addition, we analyzed the genetic distance between populations and the genetic diversity by haplotype network. We carried out a cluster analysis by Bray-Curtis index of similarity using acoustic data by UPGMA method. We correlated acoustic dissimilarities (calculated by Euclidean distance) with geographic and genetic distances among populations.

**Results.** Spectral traits of the advertisement call of *P. moratoii* presented lower coefficients of variation than did temporal traits both within and among males. Cluster analyses placed individuals without population and geographical distance congruence, but recovered the species topology in relation to sister species. The genetic distance was low among populations: it did not exceed 0.4% for the most distant populations, and was not correlated with acoustic distance.

**Discussion.** Both acoustic features and genetic sequences are highly conserved, suggesting that populations may be connected by recent migrations or that they are subject to stabilizing selective forces. Although future studies are needed, these findings contribute to a growing body of literature suggesting that this species would be a good candidate for a reintroduction program without negative effects on communication or even genetic heritage.

21 **ABSTRACT**

22 **Background.** Many amphibian species are negatively affected by habitat change due to  
23 anthropogenic activities. Populations distributed over modified landscapes may be subject to  
24 local extinction or may be relegated to the remaining—likely isolated and possibly degraded—  
25 patches of available habitat. Isolation without gene flow could lead to variability in phenotypic  
26 traits owing to differences in local selective pressures such as environmental structure,  
27 microclimate, or site-specific species assemblages.

28 **Methods.** Here, we tested the microevolution hypothesis by evaluating the acoustic parameters  
29 of 349 advertisement calls from 15 males from six populations of the endangered amphibian  
30 species *Proceratophrys moratoi*. In addition, we analyzed the genetic distance among  
31 populations and the genetic diversity by the haplotype network. We performed cluster analysis  
32 on acoustic data based on the Bray-Curtis index of similarity, using the UPGMA method. We  
33 correlated acoustic dissimilarities (calculated by Euclidean distance) with geographical and  
34 genetic distances among populations.

35 **Results.** Spectral traits of the advertisement call of *P. moratoi* presented lower coefficients of  
36 variation than did temporal traits, both within and among males. Cluster analyses placed  
37 individuals without congruence in population or geographical distance, but recovered the species  
38 topology in relation to sister species. The genetic distance among populations was low; it did not  
39 exceed 0.4% for the most distant populations, and was not correlated with acoustic distance.

40 **Discussion.** Both acoustic features and genetic sequences are highly conserved, suggesting that  
41 populations could be connected by recent migrations, and that they are subject to stabilizing  
42 selective forces. Although further studies are required, these findings add to a growing body of  
43 literature suggesting that this species would be a good candidate for individuals reintroduction  
44 program without negative effects on communication or genetic heritage.

45

## 47 INTRODUCTION

48           The greatest threat to endangered amphibians is habitat change caused by anthropogenic  
49 activities, which alters resource availability, environmental quality, and ecological processes  
50 (Metzger, 2001; Stuart et al., 2004). Such negative impacts have important implications for  
51 organisms that face new selective pressures exerted by habitat conversion (Forman, 1995). In  
52 addition, habitat fragmentation causes isolation of populations, and places them at risk of  
53 extinction owing to demographic stochasticity, genetic depression, social dysfunction, and  
54 exogenous factors such as strong climatic variations and disasters (Simberloff, 1986). Therefore,  
55 it is predicted that species affected by these changes would (1) migrate to appropriate adjacent  
56 areas; (2) undergo local decline and extinction; or (3) undergo local adaptation.

57           Surprisingly, several species thrive in modified sites even after profound anthropogenic  
58 transformation. Because these landscapes often exhibit physical, climatic, and biological (e.g.,  
59 species assemblage) shifts, the ability of the remaining species to persist is likely a consequence  
60 of phenotypic plasticity in traits such as behavior, morphology, and reproduction (Mayr, 1963;  
61 Pulido & Berthold, 2004; Merckx & Dyck, 2006).

62           One of the most important phenotypic traits in evolutionary studies of anurans is the male  
63 advertisement call, because components of these calls are fundamental to species recognition and  
64 mate choice, and are thus under sexual selection (Ryan, 1991; Wycherley, Doran & Beebee,  
65 2002; Smith, Osborne & Hunter, 2003; Kaefer & Lima, 2012; Grenat, Valetti & Martino, 2013).  
66 Moreover, calls are subject to natural selection over larger geographic ranges, mainly when  
67 populations are isolated by physical barriers (Simões et al., 2008; Kaefer, Tsuji-Nishikido &  
68 Lima, 2012; Tsuji-Nishikido et al., 2012). Because anurans tend to not disperse over long  
69 distances (Blaustein, Wake & Sousa, 1994; Tozetti & Toledo, 2005; Loughheed et al., 2006),  
70 sexual phenotypic traits in anurans are likely influenced by local environmental conditions  
71 (Bosch & de la Riva, 2004; Ey & Fischer, 2009).

72           The anuran advertisement call is a multidimensional signal that can be viewed as a  
73 collection of spectral and temporal acoustic traits that are influenced, for example, by body size,  
74 air temperature, and social context (Wells & Taigen, 1986; Gerhardt, 1991; Bee, 2002; Gerhardt  
75 & Huber, 2002; Wong et al., 2004; Toledo et al., 2015a). Therefore, sexual selection, habitat  
76 structure, and climatic conditions might all cause variation in call traits among populations (Jang  
77 et al., 2011; Faria et al., 2009 Kaefer & Lima, 2012; Kaefer, Tsuji-Nishikido & Lima, 2012;

78 Narins & Meenderink, 2014). In addition, other biotic processes, such as interspecific acoustic  
79 interactions, which generate distinctive background noise, can affect call variation among  
80 populations (Littlejohn, 1976; Höbel & Gerhardt, 2003).

81 Different traits of advertisement calls may have distinct roles in anuran communication,  
82 and therefore, may evolve by distinct selective pressures (Cocroft & Ryan, 1995; Erdtmann &  
83 Amézquita, 2009; Goicoechea, De La Riva & Padial, 2010). As a result, call traits should vary in  
84 unique and predictable ways. Gerhardt (1991) classified these traits as static or dynamic acoustic  
85 traits. Typically, spectral acoustic traits show low variability (static) and are related to  
86 conspecific recognition. Consequently, static traits are subject to stabilizing or weakly directional  
87 selection by female choice. On the other hand, most temporal acoustic traits show higher  
88 variability (dynamic) and are thought to indicate a male's investment in reproduction; these may  
89 be subject to directional selection by females for values above species means (Gerhardt, 1991;  
90 Gerhardt & Bee, 2007).

91 However, acoustic variation is not always related to genetic variation at the population  
92 level (Heyer & Reid, 2003; Loughheed et al., 2006; Kaefer et al., 2013). In these cases, despite  
93 some phylogenetic signal being recorded in vocalizations (Erdtmann & Amézquita, 2009;  
94 Goicoechea, De La Riva & Padial, 2010; Tobias, Evans & Kelley, 2011; Gingras et al., 2013),  
95 the evolution of genotypes and phenotypes (as acoustic traits) may be decoupled (Loughheed et  
96 al., 2006) or asynchronous (Kaefer et al., 2013).

97 Herein, we speculated that historical modification of landscapes by agricultural crops has  
98 created barriers among persistent populations, and affected phenotypic and genetic traits in an  
99 endangered Neotropical toad, *Proceratophrys moratoi*. We tested the hypothesis that unique  
100 selective pressures among these remaining populations have led to divergence in acoustic traits  
101 and increased genetic structure.

102

## 103 **METHODS**

### 104 **Species**

105 The genus *Proceratophrys* includes 40 South American toad species (Frost, 2015).  
106 *Proceratophrys moratoi*, originally described in the genus *Odontophrynus* (Jim & Caramaschii,  
107 1980), is a member of the *P. cristiceps* species group (Giaretta et al., 2000), lacking palpebral  
108 appendages and postocular swellings. It was described from the municipality of Botucatu, state

109 of São Paulo (Jim & Caramaschii, 1980), from where it is now extirpated (Brasileiro, Martins &  
110 Jim, 2008). Despite recent reports of new populations outside Botucatu (Brasileiro, Martins &  
111 Jim, 2008; Rolim et al., 2010; Maffei, Ubaid & Jim, 2011; Martins & Giaretta 2012), according  
112 to the current Brazilian red list, the species is endangered (EN) (MMA, 2014).

113 *Proceratophrys moratoi* is endemic to the Brazilian Cerrado and is found in open  
114 grasslands near small streams or swamps (Rolim et al., 2010; Maffei, Ubaid & Jim, 2011;  
115 Martins & Giaretta, 2012). Males call during the rainy season (generally from October to  
116 February). The advertisement call of *P. moratoi* is characterized by a single train of regularly  
117 repeated pulses. Call duration is approximately 250 ms, and the frequency ranges from 700 to  
118 1900 Hz (Brasileiro, Martins & Jim, 2008; Martins & Giaretta, 2012).

119

## 120 **Sites**

121 We studied six populations of *P. moratoi*, which represent almost its entire known  
122 geographic distribution (Martins & Giaretta, 2012). We sampled the populations in two  
123 southeastern Brazilian states (Figure 1): São Paulo (Avaré, Bauru, Itirapina and São Carlos) and  
124 Minas Gerais (Ituiutaba and Uberlândia). These regions represent an important center of  
125 agricultural and livestock production (MMA, 2005) with a remarkable history of land use  
126 modification and natural habitat devastation (Dean, 1995). With the exception of the populations  
127 from Itirapina, Bauru, and Uberlândia, which were in protected natural reserves, all populations  
128 inhabited modified landscapes.

129

## 130 **Acoustic analyses**

131 We analyzed 349 calls from 15 males of *P. moratoi* from 6 localities, 18 calls from 2  
132 males of *Odontophrynus americanus* and 6 calls from one male of *Proceratophrys boiei*. Calls  
133 were recorded using the following combinations of microphones and recorders: (1) an  
134 Audiotecnica AT 835b microphone and a Marantz PMD-222 recorder, (2) a Dynamic  
135 microphone and an Uher 4000 recorder, (3) a Sennheiser ME67/K6 microphone and a Boss 864  
136 recorder, (4) a Sennheiser ME67/K6 microphone and a Marantz PMD671 recorder, or (5) a  
137 Sennheiser ME66/K6 microphone and an M–audio Microtrack II recorder. All recordings were  
138 made with sample rate of 44.1 or 48 kHz, and at 16-bit resolution. Acoustic recordings used in  
139 the present study are available in the Fonoteca Neotropical Jacques Vielliard, with collection

140 numbers FNJV 10498, 10577, 12222–24, 12228, the Smithsonian Institution website  
141 ([http://vertebrates.si.edu/herps/frogs\\_boraceia/list.htm](http://vertebrates.si.edu/herps/frogs_boraceia/list.htm)), and the personal collection of Arioaldo  
142 A. Giaretta, which are detailed in the appendix of Martins & Giaretta (2012).

143 Acoustic analyses were performed in Raven Pro 64 1.4 for Windows (Cornell Lab of  
144 Ornithology), with the following settings: FFT (Fast Fourier Transformation) = 1024; Overlap =  
145 50 for spectral evaluations; and FFT = 256 and Overlap = 50 for temporal variables. Both  
146 temporal and spectral values were extracted from the spectrogram. We analyzed the following  
147 quantitative traits: frequency range, maximum frequency, minimum frequency, peak of dominant  
148 frequency, call duration, number of pulses per note, and pulse rate (pulses per second). Spectral  
149 measurements were obtained by selecting four variables in the source “choose measurements” in  
150 Raven: (1) Frequency 5% (Hz); (2) Frequency 95% (Hz)—these two measures include maximum  
151 frequency and minimum frequency, ignoring 5% below and above the total energy in the  
152 selected call; (3) Bandwidth 90% (Hz)—frequency range that included 90% of the energy  
153 distribution, i.e., the difference between Frequency 95% and Frequency 5%; (4) Max Frequency  
154 (Hz)—peak of dominant frequency (the frequency in which the power is maximum within the  
155 call). For temporal properties, we made precise selections on calls in the spectrogram, and  
156 visually counted the pulses.

157 We calculated the variation in quantitative acoustic variables through coefficient of  
158 variation (CV; SD/mean) for both among-males and within-males level. As defined by Gerhardt  
159 (1991), CVs can be used to determine if a call trait is static ( $CV < 5\%$  within males and  $< 12\%$   
160 among males) or dynamic ( $CV > 12\%$  within males and among males).

161

## 162 Genetic analyses

163 Liver and muscle samples from 26 *P. moratoi* individuals from six populations were  
164 collected: four populations in the state of São Paulo: Itirapina (n = 5), São Carlos (n = 5), Bauru  
165 (n = 5), and Avaré (n = 2); and two populations in the state of Minas Gerais: Ituiutaba (n = 4)  
166 and Uberlândia (n = 5). This small sample size is in part attributable to the rarity of the species,  
167 and collection restrictions, as it is endangered and apparently extinct in at least two populations.  
168 Tissues were preserved in 95% ethanol. Voucher specimens were deposited in the Coleção  
169 Científica Jorge Jim indexed in Museu Nacional, Rio de Janeiro, Brazil (CCJJ 7925, 7928-7938,  
170 7944, 7950-7952, 7958). Tissue collection can be found in the Collection of tissue and

171 chromosome preparation Shirlei Maria Recco Pimentel, Universidade Estadual de Campinas  
172 (UNICAMP), Campinas, São Paulo, Brazil (SMRP 469.01-469.14, 469.26-469.42). Total  
173 genomic DNA was extracted according to Veiga-Menocello et al. (2014). We targeted a 650-bp  
174 region of the 16S mitochondrial gene using the primers 16Sar and 16Sbr (Palumbi et al., 1991).  
175 Fragments were purified using a purification kit (GE Healthcare Life Science, São Paulo, SP,  
176 Brazil); sequences were obtained using the same primers and BigDye™ 3.1 cycle sequencing  
177 kits (Applied Biosystems Foster City, CA, USA), and were read on an ABI 3700/Prism.  
178 Sequences were checked by eye using BioEdit v.5.0.9 and aligned with Muscle (Edgar, 2004).  
179 Genetic distances (*p* distances) were computed from mitochondrial loci using MEGA 5.1  
180 (Tamura et al., 2011).

181 We verified haplotypes using DnaSP v. 5.10.01 (Librado & Rozas 2009). We obtained a  
182 haplotype network using the Median-joining network method (Bandelt, Forster & Rohl, 1999)  
183 with NETWORK 4.6.1.2.

184

### 185 **Statistical analyses**

186 We performed cluster analyses based on acoustic similarities using the Bray-Curtis index,  
187 through the UPGMA method and bootstrap with 1000 randomizations (see Toledo et al., 2015b).  
188 We calculated the values for Euclidean distance among populations for acoustic traits, and  
189 correlated them with the values for geographical and genetic distance through Mantel tests with  
190 1000 permutations. Geographical distance was estimated in Google Earth as the straight-line  
191 distance between two sites. We conducted statistical analyses in Past 2.17 (Hammer, Harper &  
192 Ryan, 2001)

193

## 194 **RESULTS**

### 195 **Acoustic similarities and variability**

196 The structure of calls from all individuals presented the same pattern of a single periodic  
197 pulse train (Figure 2a). However, we found slight differences in spectral and temporal traits  
198 among calls from distinct localities (Table 1). Male calls from Avaré had the lowest frequencies,  
199 whereas calls from Ituiutaba had the highest frequencies. The individual from São Carlos  
200 presented the longest calls, whereas the individual from Bauru emitted the shortest calls. Males  
201 from Itirapina emitted calls with the highest pulse rates; the call from the male from Avaré had

202 the lowest pulse rate. Temporal traits of the advertisement call presented high coefficients of  
203 variation among males (above 12%), and were considered dynamic (Figure 2b). Among the  
204 spectral traits, frequency range showed the highest coefficient of variation among males, whereas  
205 the other three spectral traits presented an intermediate variation (between 5 and 12%; Figure  
206 2b). All call traits presented low variation within males, with CVs of lower than 8% (Figure 2c),  
207 and the majority was considered static, with <5% variation.

208 Cluster analysis placed *O. americanus* and *P. boiei* as outgroups in relation to the focal *P.*  
209 *moratoi* individuals (Figure 3). Individuals were not grouped by population, except for the males  
210 from Itirapina. The male from Avaré had the most distinct call, and was grouped with two  
211 individuals from Uberlândia. However, other males from Uberlândia were placed in the other  
212 two major groups, and individuals were not organized according to geographical distance among  
213 populations. This was confirmed by the absence of a correlation between geographical distance  
214 and the acoustic distance between populations ( $r = -0.23$ ;  $P = 0.73$ ).

215

#### 216 **Haplotype network and genetic distance**

217 We found 7 haplotypes in the 26 partial sequences of the mitochondrial 16S gene (Figure  
218 4). Most haplotypes (H1–H4) were shared among multiple populations, but three haplotypes  
219 (H5–H7) were found in one individual each, and were limited to Uberlândia (H5, H6) or  
220 Ituiutaba (H7). Genetic distances of *P. moratoi* averaged 0.2% (0.0–0.4) between populations  
221 (Table 2) and 0.25% (0.0–0.5) within populations. Acoustic and geographical distance between  
222 populations was not correlated with genetic distance ( $r = -0.32$ ;  $P = 0.86$ ; and  $r = -0.32$ ;  $P =$   
223 0.87).

224

#### 225 **DISCUSSION**

226 In the present study, we found a common structural pattern (a single periodic pulse train;  
227 Fig. 1) for all individuals, which is consistent with the findings of previous reports on the  
228 advertisement call of *P. moratoi* (Brasileiro, Martins & Jim, 2008; Martins & Giaretta, 2012).

229 The variability in the advertisement call of *P. moratoi* follows a general pattern among  
230 anurans; spectral traits exhibit lower variation than do temporal ones, with the exception of  
231 frequency range (Gerhardt, 1991; Gerhardt & Huber, 2002). The low coefficients of variation in  
232 call traits we observed among males (showing highly stereotyped signals) could be attributed to

233 stabilizing selection (Kaefer & Lima, 2012; Kaefer, Tsuji-Nishikido & Lima, 2012), which is  
234 usually a result of generalized female choice (Jennions & Petrie, 1997). Alternatively, it could  
235 reflect the absence of selection and the presence of neutral/stochastic processes (Edrtmann &  
236 Amézquita, 2009; Kaefer et al., 2013; Toledo et al., 2015b). Because sexual signals carry  
237 important information for mate recognition (Ryan, 1991), spectral traits would not be expected to  
238 diverge rapidly. Temporal traits, which are generally dynamic, have been shown to vary with  
239 social or environmental conditions (Bosch & de la Riva, 2004; Ey & Fischer, 2009). For  
240 example, some species respond to vocal interactions and chorus composition with rapid temporal  
241 adjustments in their calling behavior (Schwartz, 2001). Therefore, temporal traits such as pulse  
242 rate and call duration may be affected by social context. In species wherein females make  
243 choices based on temporal traits alone (Littlejohn, 1965), these temporal traits would be  
244 predicted to minimize the patterns observed in spectral traits. However, we observed that mate  
245 choice by acoustic properties remains to be tested, since we do not know how female *P. moratoi*  
246 individuals select males.

247         Habitat structure, background noise, and other environmental differences are pivotal in  
248 the evolution of acoustic communication in frogs (Goutte, Dubois & Legendre, 2013; Schwartz  
249 & Bee, 2013). These factors certainly contribute to regional divergence in call traits among  
250 individuals (Amézquita et al. 2006). Each reproductive environment could present distinct  
251 species composition and considerably different acoustic qualities. Based on this ecophenotypic  
252 hypothesis, we expected that local pressures would modulate call features in *P. moratoi* males  
253 from distinct localities, because populations of this threatened species surrounded by human-  
254 transformed landscapes could show low connectivity. In contrast, cluster analyses failed to group  
255 individuals by population (geographical context). Taken together, these results indicate minimal  
256 pressure for signal divergence, which could be explained by the following, non-exclusive  
257 hypotheses: (1) the reproductive environment in the sampled localities is similar with respect to  
258 habitat structure and background noise; (2) the female choice drives stable selection, which  
259 equalizes the general acoustic features of males from different localities; (3) the populations  
260 were recently connected, presenting traces of recent genetic flow; and (4) random evolutionary  
261 processes act on the calls (Toledo et al., 2015b). We did not test these hypotheses, but it is  
262 unlikely that populations were recently connected, as genetic distance was not correlated with  
263 acoustic distance among populations. Furthermore, although some studies have reported a

264 correlation between genetic and acoustic distances (Smith, Osborne & Hunter, 2003; Amézquita  
265 et al., 2009), many others have shown that geographical variation in sexual signals and genetic  
266 distances among populations do not co-vary (Heyer & Reid, 2003; Lougheed et al., 2006; Pröhl  
267 et al., 2007). In these cases, it is possible that evolution has been decoupled for genotypic and  
268 phenotypic features (Lougheed et al., 2006). Cluster analysis demonstrated that a phylogenetic  
269 signal in anuran advertisement call (as a phenotypic trait) might not evolve as rapidly as DNA  
270 differences appear, a finding corroborated by Kaefer et al. (2013). Consequently, our results  
271 suggest that a phylogenetic signal would be apparent only when higher taxonomic levels are  
272 compared, for example, different species, genera, or families. This finding could be explained, in  
273 part, by the conservative nature of the molecular marker used—the 16S gene—which is  
274 commonly employed to separate different species (Fouquet et al. 2007; Brusquetti et al. 2014;  
275 Yang et al., 2014; Lourenço et al. 2015).

276         Although our dataset is limited, we observed that acoustic and genetic variation appears  
277 to be conserved among individuals distributed across human-altered landscapes. Our preliminary  
278 results showed similar call types and genotypes (also presenting low genetic divergence) among  
279 different populations. Such reduced acoustic and possible genetic structure could be considered  
280 in future conservation actions; for example, these findings suggest that communication barriers  
281 (prezygotic) would pose no obstacle to reproduction (Dobzhansky, 1951; Tucker & Gerhardt,  
282 2011) if a reintroduction program were initiated for this species. Nevertheless, playback  
283 experiments are required for testing this hypothesis first. From the genetic point of view, if the  
284 actual molecular marker used in the present study could represent the genomes of all individuals,  
285 the genetic barrier (postzygotic) would pose no obstacle to reproduction too (Dobzhansky, 1951;  
286 Tucker & Gerhardt, 2011). The type locality of this species (Botucatu) is still preserved, and a  
287 reintroduction could be considered after complementary genetic, natural history, and  
288 experimental research. The causes of the decline of this population are unknown, and therefore, a  
289 reintroduction initiative could also aid in understanding past decline (if the cause is still active)  
290 and help to prevent further decline here (for example, of *Bokermannohyla izecksohni*—another  
291 species that could be threatened in Botucatu; L. F. Toledo & C. Z. Torres, unpublished data) and  
292 elsewhere. Thus, the findings of the present study add to the growing body of literature  
293 supporting *P. moratoi* as a potential candidate for conservation actions, although additional work  
294 is necessary before an action plan could be initiated

295

296 **ACKNOWLEDGMENTS**

297 Ariovaldo A. Giaretta helped in fieldwork and recorded specimens in Uberlândia and  
298 Ituiutaba. We are grateful to Luciana B. Lourenço and Shirlei M. Recco-Pimentel for their  
299 support in genetic analysis. Pertinent comments and English language review were provided by  
300 Kristine Kaiser from the Society for the Study of Amphibians and Reptiles (SSAR).
